The United States Government was represented by the Director of this Office and the State government by the governor, superintendent of public instruction, and other officials. Matters relating to the general interests of education throughout the country were presented by Superintendent L. D. Harvey, of Wisconsin, and A. E. Winship, editor of the *Journal of Education*, Boston. Most of the sessions were held in buildings of the University of California, and President Wheeler and a considerable number of members of the university faculty took part in the meetings. Other universities and the normal schools were also represented. The interests of various grades of schools from the university down to the kindergarten were discussed. Members of the legislature, city officials, editors, librarians, farmers, and business men also participated.

It was, therefore, of unusual significance that at such a meeting the claims of agricultural education to a place in the public school system in secondary and elementary schools, as well as in the college, were elaborately and earnestly presented and discussed by a considerable number of speakers. More significant even was the general atmosphere of sympathy with the idea that the industrial element must in one form or another become a permanent and pervasive constituent of our public school system.

This was impressively enforced by the earnest and thoughtful address of Governor Pardee, in which unanswerable statistics were made to show that the children, and especially the boys, were in the vast majority of cases leaving school at so early an age that the schools were making little impression on their minds or characters; that there was little in the school curricula to aid them in their life work, and

that as a result of the present educational conditions very many of the youth of the State at the best were becoming inefficient industrial workers or at the worst were drifting into criminal courses.

Thus it was made easier for other speakers to emphasize the importance of the industrial element in education as a means both of holding children longer in the schools and of training them for the actual duties of life. And in the discussion of industrial education it was made plain that in order to prepare the children of the country for life on the farm and to interest them in the business of farming as a life work, the atmosphere of the rural schools must be favorable to country life, and the instruction in these schools must open the minds of the children to the rational interest which may be connected with farming, and to the aid which the farmer may get from the application of science to his art.

Ample opportunity was given for the presentation of various phases of the problem of agricultural education. The progress which has been made in different States and foreign countries in introducing instruction in agriculture into the schools was also shown. That there was great public interest in the question of agricultural education was evidenced by the relatively large attention which was given to this feature of the meeting by the press throughout the State.

The importance of such a meeting at this juncture is relatively great, because it gives the friends of agricultural education an opportunity to reach the great body of school officers and teachers, whose support must be enlisted before any scheme for agricultural instruction in the public schools can be made effective in our educational system. It helps, moreover, to give the general public some idea of what is really involved in such instruction in the public schools and to remove erroneous notions of the extent and character of the proposed innovation.

The important fact was brought out that already some instruction in agriculture and closely related subjects is being successfully given in quite a number of schools in California, and an organization was formed for the more definite formulation of school courses in this subject for use in the public schools throughout the State.

The California meeting is an impressive evidence of the interest which in many parts of the United States is now being manifested in the wider diffusion of agricultural education. By bringing schoolmen and farmers together to discuss this question the Californians took a course well adapted to promote the cause of agricultural education, and it is hoped that this line of effort may be repeated in the near future in many States.

The decision to establish an institute of animal nutrition is the latest step in the direction of specialization in agricultural investigation.

This was determined upon at a recent meeting of the board of trustees of the Pennsylvania State College, and will be put into effect at an early date. As an outgrowth of experiment station work the matter is of unusual interest, and as indicating a determination to make the investigation in this line an even greater feature at the Pennsylvania Station it is matter for sincere congratulation.

The institute will correspond in organization and general character to the institutes common at European universities. The action is in effect the elevation of this important department of research to a position coordinate with that of the experiment station itself, and in a sense independent of it. It will be conducted as a department of the college and will be presided over by a separate director responsible to the college authorities, but will be affiliated with the station in its work. The organization, therefore, is different from anything we have had in the past.

Dr. H. P. Armsby, who has been since 1888 director of the Pennsylvania Station, has been indicated as the director of the new institute. As such he will be relieved of all duties relating to the general administration of the experiment station, and will be left free to confine himself to his special lines of research. Coming as it does at the close of a long period of service, in which Doctor Armsby has displayed high ability as a research worker in this field, this action of the board is to be regarded as a marked compliment to him and a declaration of confidence and appreciation. It is a decided promotion, carrying with it greater freedom and opportunity, and is understood to be entirely in accord with Doctor Armsby's tastes and wishes.

There would seem to be great opportunity for an institute of this character. Its work will be of interest and value to all the stations and to the science of animal nutrition. It will conduct investigations which very few stations are in position to undertake on account of the expense involved, the intricate apparatus and equipment required, and above all the indispensable special training. The work is not spectacular and not likely to appeal so strongly to men looking for immediate practical ends. Support for it must come mainly from investigators and others who appreciate its importance. It calls for a patient investigator, who is a thorough scholar in disposition and temperament, and is content to make haste slowly. In all these respects Doctor Armsby will be recognized as preeminently qualified.

A point has been reached in the feeding studies where further knowledge of the physiology of nutrition is indispensable if progress is to be made in working out the laws which underlie practice. The more superficial work has been done. The composition and digestibility of all the principal feeding stuffs have been determined, as well as their general effects when fed. The practical feeder has been overtaken and his empirical rules largely mastered. But to build up a science of

feeding requires a more thorough understanding of the fundamentals of animal nutrition, the relations of supply to demand in animal economy and between cause and effect.

There is a feeling that the limit of scientific advancement in feeding by the ordinary methods of investigation has about been reached. Many experimenters, realizing the weakness of their present position, are making feeding work a less prominent feature than formerly. We are ready for the more fundamental work, and the need of it is far more widely felt than it was a few years ago. The real problems of feeding and nutrition are felt to be very intricate, far too much so for the experimenter without special training and equipment. They demand the undivided attention of specialists, with a reasonable assurance of continued support for a term of years.

Little advancement in scientific cheese making was made until the nature of the changes, the causes operative, and the effect of conditions on the development of these causes had been found out. Then a sound, intelligent basis for action was at hand. The same applies to the feeding question, although there the problem is even more complex and individuality will always have to be taken into account.

With the sentiment which has developed in recent years there should be abundant support for this higher research work in animal nutrition. The problems presented are national ones in their breadth of interest and importance, and hence the participation of the General Government in carrying on the investigations seems particularly fitting and desirable. Having devised and built in this country an apparatus which is regarded as a model for this character of investigation, it is greatly to be desired that opportunity be afforded for utilizing it to the fullest extent and getting the most possible out of it.

From every point of view, therefore, the action of the Pennsylvania board of trustees in setting this work off by itself and indicating a policy of fostering it by liberal appropriations seems worthy of special commendation. Investigation of this high order lends solidity to the station work in animal husbandry, and by reflection affects the standing of the work as a whole.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

On the formation of ammonia from the elements, F. HABER and G. VAN OORDT (*Ztschr. Anorgan. Chem., 44 (1905), No. 4, pp. 341–378, figs 3; abs. in Chem. Ztg., 29 (1905), No. 46, Repert. No. 12, p. 162*).—The ammonia equilibrium at various temperatures up to 1,020° C. was restudied.[a]

The ammonia content of a mixture of nitrogen, hydrogen, and ammonia in equilibrium under a pressure of one temperature was found to be 98.51 per cent at 27° C., 8.72 per cent at 327° C., 0.21 per cent at 627° C., 0.024 per cent at 927° C., and 0.012 per cent at 1,020° C. It is claimed that the reversible reaction $Ca_3N_2 + 3H_2 \rightleftarrows 3CaH_2 + N_2$ takes place readily at red heat in connection with the reaction $N_2 + 3H_2 = 2NH_3$. Calcium compounds of nitrogen assist in synthesis of ammonia at such high temperatures as to make their use impracticable. Manganese may possibly prove of value as a catalyser in such reactions, although the high temperatures required with this substance, as with calcium compounds, render its use of doubtful practicability.

The direct synthesis of ammonia, E. P. PERMAN (*Proc. Roy. Soc. [London], Ser. A, 76 (1905), No. A 508, pp. 167–174*).—This article records the results of attempts to synthesize ammonia with a view to determining whether there is a state of equilibrium between ammonia and its constituent elements at various temperatures ranging as high as 1,100° C. The experiments were conducted with carefully dried and purified mixtures of nitrogen and hydrogen prepared (1) by decomposing ammonia in red-hot iron tubes, and (2) by mixing 1 volume of nitrogen obtained by heating ammonium chlorid and sodium nitrite and 3 volumes of hydrogen obtained by action of potash solution on metallic aluminum.

The influence not only of different degrees of temperature but also of the presence of various catalyzing agents was studied. Comparative studies of synthesis by explosion and by electric discharges were also made.

The author concludes from the results obtained that ammonia can not be synthesized by heat except under certain special conditions. He therefore regards the decomposition of ammonia by heat as an irreversible reaction.

He shows that "ammonia may be synthesized in small quantities from its constituent elements (*a*) by heating with many of the metals, (*b*) by exploding with oxygen, (*c*) by sparking. These are reversible reactions.

"It would appear that the synthesis of ammonia is effected only when the gases are ionized; the ionization would be brought about by sparking, or by the high temperature of the explosion of hydrogen and oxygen. The immediate decomposition of the ammonia formed would be prevented by its sudden cooling. The metals in the presence of moisture also produce 'nascent' or ionized hydrogen.

"It does not appear that nitrids of the metals form an intermediate stage in the formation of ammonia, for it was found that metals readily forming nitrids, e. g., magnesium, did not produce more ammonia than the others.

[a] For account of previous studies see Ztschr. Anorgan. Chem., 43 (1905), p. 111.

"There is a close analogy between ozone and ammonia with regard to their synthesis and decomposition; both are formed by sparking, and both are completely decomposed by heat."

The author criticizes the attempt of Haber and van Oordt, noted above, to fix the dissociation constant of ammonia at different temperatures as based upon entirely insufficient data.

On the formation of ammonia from the elements, F. HABER and G. VAN OORDT (*Ztschr. Anorgan. Chem., 47 (1905), No. 1, pp. 42–44*).—This is a defense of the authors' investigations on this subject against the criticism of Perman, noted above. It is also pointed out that Perman's article is not clear as to the part played by vapor of water in the synthesis of ammonia by heat.

The action of nitrogen on water vapor at high temperatures, O. F. TOWER (*Jour. Amer. Chem. Soc., 27 (1905), No. 10, pp. 1209–1216*).—Studies are reported of the rate and extent to which nitrogen combines with the oxygen of water vapor at high temperatures. The amounts of nitric acid which were formed in the experiments reported were very small, and it is shown that theoretically only 0.33 per cent of a gaseous mixture of 3 parts nitrogen and 1 part water vapor can be expected to be converted into nitric oxid at a temperature of 2,000° C. and 1.5 per cent at a temperature of 3,000° C.

The action of nitrogen on water vapor, O. F. TOWER (*Ber. Deut. Chem. Gesell., 38 (1905), No. 12, pp. 2945–2952*).—Noted above from another source.

Nitric acid from air, H. R. CARVETH and C. L. RAND (*Sibley Jour. Engin., 1905, May; abs. in Engin. and Min. Jour., 80 (1905), No. 11, p. 485*).—The authors review the various processes which have been devised for the production of nitric acid by electrical discharges through air, and give a table showing the approximate yields obtained by various experimenters as follows:

Nitric acid produced by different electrical methods.

Date.	Experimenter.	Nitric acid per kilowatt hour.
		Grams.
1897..	Rayleigh	49.1
1900..	McDougal and Howles (best yield)	33.8
1902..	Kowalski	55.0
1903..	Muthmann and Hofer	70.0
1897..	Crookes	74.0
1902..	Bradley and Lovejoy	83.0
1904..	Birkeland and Eyde	110.0

It is thought that these results "indicate that commercial success may yet be attained. The main improvements which may possibly have an advantageous influence on the yield of nitric acid by the electric flame are: (*a*) A vessel so designed as to produce the best hot-cold effect; (*b*) spark long drawn out; (*c*) low current and rapid alternations; (*d*) increased pressure; (*e*) rapid passage of gases and the introduction of the gases in the correct proportions; (*f*) temperature below 1,200° C."

It is considered probable, however, that indirect methods, such as the nitrid or cyanid process, may be found to be more economical.

On the oxidation of the nitrogen of the air by means of electrical discharges, F. VON LEPEL (*Ber. Deut. Chem. Gesell., 38 (1905), No. 11, pp. 2524–2533, figs. 2*).—This is a continuation of previous investigations (E. S. R., 15, p. [illegible]) in which the author describes apparatus and results obtained in experiments in which [illegible] oxidation was observed in case of electrodes rotating in opposite directions. The effect of previous warming of the air and of altering the form of the apparatus was also studied.

Oxidation of atmospheric nitrogen in the high tension arc, A. STAVENHAGEN (*Ber. Deut. Chem. Gesell.*, *38* (*1905*), *No. 9, pp. 2171–2177; abs. in Jour. Chem. Soc.* [*London*], *88* (*1905*), *No. 514, II, p. 517*).—"Air was forced at known rates through a cooled porcelain tube containing two iron electrodes; the tension was about 20,000 volts and the current 0.07 ampere, the discharge being a continuous greenish-yellow flame. Large quantities of oxids of nitrogen were formed, the yield being a maximum when air was forced through at a velocity of 180 liters per hour. It is impossible to completely condense all the oxids of nitrogen formed in this manner even by means of liquid air."

The examination of cyanamid and applications of the method, R. PEROTTI (*Gaz. Chim. Ital.*, *35* (*1905*), *II, pp. 228–232; abs. in Chem. Centbl.*, *1905, II, No. 14, p. 1053*).—It is stated that cyanamid reacts with silver nitrate in presence of ammonia to form silver cyanamid and nitric acid, 1 cc. of hundredth-normal silver solution corresponding to 0.00021 gm. cyanamid.

To the silver nitrate made slightly alkaline with ammonia add the cyanamid solution drop by drop with shaking and gentle warming. Filter after the solution has cleared and wash the precipitate with weak ammonia, add 3 or 4 drops of iron alum and nitric acid to the filtrate, and titrate with hundredth-normal rhodan-ammonium. The method is applicable to commercial calcium cyanamid (lime nitrogen), the solution of the material to be tested being obtained by 12 hours' standing in the cold and each cubic centimeter of hundredth-normal silver nitrate used, corresponding to 0.0004 gm. calcium cyanamid.

Expulsion of ammonium salts after precipitation in their presence, P. JANNASCH (*Jour. Prakt. Chem.*, *n. ser.*, *72* (*1905*), *No. 13, p. 38; abs. in Jour. Chem. Soc.* [*London*], *88* (*1905*), *No. 515, II, p. 611*).—"Large quantities of ammonium chlorid are expelled from solutions by evaporation with concentrated nitric acid containing nitrous acid."

The true atomic weight of nitrogen, G. D. HINRICHS (*Compt. Rend. Acad. Sci.* [*Paris*], *140* (*1905*), *No. 24, pp. 1590, 1591*).—Evidence is cited to show that the atomic weight of nitrogen is exactly 14.

A revision of the atomic weight of potassium, E. H. ARCHIBALD (*Proc. and Trans. Roy. Soc. Canada, 2. ser.*, *10* (*1904*), *Sec. III, pp. 47–53, fig. 1*).—A series of studies of the atomic weight of potassium based upon analysis of potassium chlorid is reported, the average results giving an atomic weight for this element of 39.14.

On the determination of assimilable phosphoric acid in soil, A. S. KUDASHEV (*Zhur. Opuitn. Agron.* (*Russ. Jour. Expt. Landw.*), *6* (*1905*), *No. 4, pp. 437–456*).—The author recommends ½ per cent oxalic acid as a reagent for determining the assimilable phosphoric acid in soils and reports tests of the reagent on 62 samples of chernozem soil. In all cases the more fertile soils yielded the larger amount of phosphoric acid soluble in the reagent. Soils treated with manure were also found to contain more phosphoric acid soluble in the reagent than untreated soils.—P. FIREMAN.

Action of phosphates on platinum when heated with it in the presence of carbon, W. P. HEADDEN (*Proc. Colo. Sci. Soc.*, *8* (*1905*), *pp. 45–49; abs. in Jour. Amer. Chem. Soc.*, *27* (*1905*), *No. 11, Rev., p. 615*).—The deterioration of platinum crucibles when repeatedly used for the ignition of ammonium-magnesium phosphate is explained as due to the formation of platinum phosphid.

A study of various methods for the determination of aluminum in the ash of plants, H. PELLET and C. FRIBOURG (*Ann. Chim. Analyt.*, *10* (*1905*), *No. 10, pp. 376–381*).—Tests of the methods of Carnot, Lasne (E. S. R., 7, p. 915), and Sainte-Claire-Deville, as modified by L'Hôte, are reported. As a result of these tests the author prefers the method of Carnot, although he considers that of Lasne equally good but somewhat longer.

A method for the determination of carbonates in soils, A. AMOS (*Jour. Agr. Sci., 1 (1905), No. 3, pp. 322–326, fig. 1*).—The author reports the successful use on soils containing very small amounts of calcium carbonate of a form of Brown and Escombe's modification of Hart's method. This is based on absorption of the carbon dioxid driven off from the soil sample (by boiling with hydrochloric acid) in a 4 per cent solution of sodium hydroxid in a Reiset absorption apparatus, and double titration, first with phenolphthalein and then with methyl orange as indicator, of the mixed solution of sodium hydroxid and sodium carbonate obtained.

Contribution to chemical methods of water examination, A. BÖMER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), pp. 129–143; abs. in Chem. Centbl., 1905, II, No. 10, pp. 788, 789*).—This article discusses the results of examinations of various samples of water from moors, wells, and springs, especially with reference to their suitability to domestic and industrial purposes.

Some points about water analysis, C. D. HOWARD (*N. H. Sanit. Bul., 2 (1905), No. 9, pp. 145–148*).—A brief discussion of the value of analysis for judging of the sanitary condition of waters and of the sources and means of prevention of contamination of the water supply.

A modification of Winkler's method of determining oxygen in water, H. NOLL (*Ztschr. Angew. Chem., 18 (1905), No. 45, pp. 1767, 1768*).—The essential feature of the modification is the reversal of the order of addition of manganous chlorid and potassium iodid, the addition of the iodid following that of the chlorid in the Noll modification instead of preceding, as in Winkler's original method. It is claimed that in this way more accurate results are obtained.

Note on the report of the work of the international committee for the analysis of commercial fertilizers and feeding stuffs to the Fifth International Congress of Applied Chemistry at Berlin, 1903, T. B. WOOD (*Jour. Agr. Sci., 1 (1905), No. 3, pp. 366–373*).—The history of the work of this committee is briefly outlined and the recommendations which were presented and unanimously accepted at the Berlin congress are given

Chemical analysis of feeding stuffs and its relation to feeding experiments, V. STORCH (*Ber. K. Vet. og Landbohojskoles Lab. Landokonom. Forsog [Copenhagen], 58 (1905), pp. 180, charts 8*).—The author gives an historical sketch of the development of the analysis of feeding stuffs and the various methods by which attempts have been made since Thaer's time to determine feeding value. He also presents a critique of the so-called Weende methods of analysis, and explains in detail the methods employed in the analysis of feeding stuffs by the chemical department of the Copenhagen Experiment Station.

The faults of the conventional methods of determining nitrogenous components, cellulose (crude fiber), and nitrogen-free extract are discussed at length and available data summarized. The author recommends that albuminoid nitrogen be determined instead of total nitrogen. Since the variations in the nitrogen content of the various nonalbuminoid components in plants and feeding stuffs are so great as to preclude the adoption of any single conversion factor, he advocates doing away with the factor 6.25 for conversion of albuminoid nitrogen to albuminoids, and, on the basis of the results of the investigations of Ritt[illegible], [illegible]nden, and Osborne, suggests that the factors 6.0, 5.7, and 5.5 be adopted for substances of different origin, as follows: For corn, oats, buckwheat, white beans, soja beans, rape [illegible] cakes, potatoes, mangolds, hay and straw, the factor 6.0. For wheat, rye, barle[illegible]heat bran, rye bran, peas, horse beans, vetches, sesame ca[illegible] and candlenut ca[illegible] the factor 5.7; and for peanut cake, cottonseed cake, sunflower seed cake, linseed [illegible] hempseed cake, almond cake, cocoanut cake, and Brazil nut cake, the factor [illegible]

The various methods proposed for the determination of cellulose (crude [illegible] considered at length, comparative results being given. According to the [illegible] [illegible]isfactory method for determining this constituent is available as yet [illegible] rec-

ommends that it be determined by difference. The fact is recognized that the errors introduced in the proposed methods of determining protein and cellulose affect the figures for nitrogen-free extract, as well as the calculated nutritive ratios.

In general the author recommends that the following components of feeding stuffs be determined, viz, fat, albuminoids, sugar, starch, pentosans, ash, and water, with cellulose and other nondeterminable substances grouped by difference. This scheme of analysis has been in use in the chemical department of the Copenhagen station during recent years. A number of analyses made by the proposed methods are given. The bearing of these methods of analysis on digestion coefficients is discussed.—F. W. WOLL.

Methods of estimating fat, G. ROSENFELD (*Centbl. Inn. Med., 1905, No. 14; abs. in Biochem. Centbl., 3 (1905), No. 23, pp. 739, 740*).—The author concludes, from a study of different methods, that twice boiling with alcohol for a quarter of an hour and extracting 6 hours with chloroform is the most satisfactory method of estimating fat, both as regards the quantity extracted and its freedom from nitrogen.

The determination of fat and water in butter by the Gerber method, A. HESSE (*Milchw. Zentbl., 1 (1905), No. 10, pp. 433-444*).—The Gerber methods for the rapid determination of fat and water in butter were tested and found, according to the author, to be unsuitable for both control work and purposes of investigation.

Tests of Sichler's "sin-acid" butyrometry, LOTTERHOS (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 10, pp. 596-599*).—Comparative determinations by the Sichler and gravimetric methods were made on milk, skim milk, buttermilk, curdled milk, milk preserved with potassium bichromate, formaldehyde, and copper sulphate, and cream. The author concludes that the Sichler nonacid method in its present form is of equal value to the Gerber acid method.

The determination of the fat content of butter by the method of Gottlieb, A. BURR (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 5, pp. 286-290*).—The author considers the Gottlieb method of determining fat in milk applicable, with more or less modifications, to all forms of dairy products.

On the examination of curdled milk, VON WISSELL (*Milchw. Zentbl., 1. (1905), No. 9, pp. 401-417*).—Determinations of fat, total solids, and specific gravity were made on sweet and curdled milk with and without previous treatment with ammonia.

The results for fat by the gravimetric method and the methods of Gottlieb and Gerber showed practically no influence due to the souring of the milk or the addition of ammonia. Curdled milk rendered fluid by the addition of ammonia showed, however, too low a percentage of total solids and too high a specific gravity. It is believed that these determinations may be corrected by adding 0.44 to the former and deducting 0.001 from the latter.

Contribution to the knowledge of sesame oil, H. SPRINKMEYER and H. WAGNER (*Ztschr Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 6, pp. 347-353*).—Analyses were made of samples of sesame oil from India, the Levant, and Africa. No marked differences in chemical or physical properties were observed in the case of samples from the first two sources. The African oil showed higher iodin and refractometer numbers. A modification of the Baudouin test for the detection of sesame oil in butter is described.

The guaiac reaction of milk, A. ARNOST (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 9, pp. 538-540*).—The results of the author's investigations confirm those of [illegible]mann-Wender and of Liebermann that the guaiac solution used in distinguishing raw from cooked milk becomes active after exposure to light and air, and also the observation of Zink that the acetone solution gives a reaction even in a fresh condition.

The use of fermentation methods in the laboratory; a contribution to the study of starch sirups, VON RAUMER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 9 (1905),*

No. 12, pp. 705–726).—Different commercial yeasts and pure cultures were studied with special reference to the examination of sirups. In the author's opinion, since pure cultures can not always be obtained in all laboratories, beer yeast may be used and will give satisfactory results in the estimation of dextrin. When it is desirable to determine maltose in addition to glucose and dextrin, wine yeast may be used.

A new indirect method of determining aldehyde in lemon oil, E. BERTÉ (*Chem. Ztg., 29 (1905), No. 60, pp. 805, 806*).—The method depends upon the differences noted with the polariscope in liquid lemon oil before and after it has been acted upon by potassium bisulphite, as in the method previously described by Berté and Soldaini.[a]

The estimation of the fusel oil of alcoholic liquors, E. BECKMANN (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 1–2, pp. 143–152*).—Improved methods of estimating fusel oil are described.

Contribution to our knowledge of the action of pepsin, with special reference to its quantitative estimation, P. W. COBB (*Amer. Jour. Physiol., 13 (1905), No. 5, pp. 448–463, figs. 3*).—A study of the comparative merits of different methods for the quantitative estimation of pepsin is reported. Some of the conclusions which were drawn follow:

"Making all due allowances for errors due to the [Metts] method itself, pepsin solutions capable of digesting 4 mm. or over in 24 hours give results far below those anticipated by the rule of square roots from the amount of pepsin present. No calculation can be made in any case as to the absolute or relative pepsin values until the question of inhibition is eliminated. Commercial pepsin sometimes contains considerable amounts of inhibitory substance, evident in solutions of $\frac{1}{64}$ per cent strength. And in regard to the albumin-froth method of Bettman and Schroeder: Results obtained by it can not be justifiably expressed in figures indicative of pepsin-concentration, but only by such expressions as 'strong,' 'very strong,' 'moderate,' etc."

The estimation of boric acid, W. VAUBEL and E. BARTELT (*Chem. Ztg., 29 (1905), No. 46, pp. 629, 630*).—The detection of boric acid with curcuma paper and its estimation by the Jörgensen titration method are discussed on the basis of personal experience.

Among other precautions the authors note that the Jörgensen method does not give satisfactory results when phosphoric acid is present and that sulphurous acid must be removed before the method can be applied. Any strong acid other than boric should be neutralized, and when this is done methyl orange may be used as an indicator.

Modification of Hehner's test for formaldehyde, A. B. LYONS (*Pharm. Jour. [London], 75 (1905), p. 443; abs. in Jour. Soc. Chem. Indus., 24 (1905), No. 20, p. 1086*).—In using Hehner's test for the detection of formaldehyde in other solutions than milk, the author recommends the addition of beef peptone instead of milk and states that this test is capable of detecting 1 part of formaldehyde in 4,000,000.

Strychnin tannate and its use in the analysis of tanning materials, S. R. TROTMAN and J. E. HACKFORD (*Jour. Soc. Chem. Indus., 24 (1905), No. 21, pp. 1096–1100, fig. 1*).—Objections to the hide powder method and the collin method of Parker and Payne for tanning materials are pointed out, and a method based upon the precipitation of tannic acid with strychnin sulphate is described.

The use of the electric current in quantitative determinations in food analysis, G. RUPP (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 1–2, pp. 37–41*).—A paper with discussion presented before the meeting of German Food Chemists in Dresden, 1905. The method proposed depends upon the resistance of different liquids to the passage of an electric current.

[a] Chem. and Drug., 1903, Sept.

Outlines of physiological chemistry, S. P. BEEBE and B. H. BUXTON (*New York and London: The Macmillan Co., 1904, pp. VIII+195, figs. 3, dgms. 4*).—Theoretical questions connected with physiological chemistry are discussed in this volume, special attention being paid to chemical formulas and reactions. Some of the chapters deal with the following topics: Theory of solutions, ionization; chemistry of carbon compounds, cyclic compounds, proteids, enzyms, and disease and immunity.

Studies and observations of agricultural chemical experiment stations in continental Europe, H. G. SÖDERBAUM (*Meddel. K. Landtbr. Styr. [Stockholm], 1905, No. 102, pp. 52*).—The observations refer to the following stations visited by the author: Berlin, Halle, Leipsic, Möckern, Dresden, Pommritz, Prague, Vienna, Kronenburg, Leopoldskron, Munich, Hohenheim, Nancy, Paris, Gembloux, Wageningen, Groningen, Bremen, Kiel, and Copenhagen.

METEOROLOGY—WATER.

Report of Interstate Astronomical and Meteorological Conference, Adelaide, May, 1905 (*Adelaide: C. E. Bristow, 1905; rev. in Nature [London], 73 (1905), No. 1879, p. 8*).—This report, prepared in view of the possible reorganization of the astronomical and meteorological service under the federal government of Australia, describes briefly present arrangements for such work in the several colonies of the commonwealth.

It also outlines a plan for future observations, based upon "the idea of the establishment of a central federal institution for theoretical and scientific meteorology, 'where the observations for the whole of Australia should be collected, discussed, and published, and where all the higher problems of meteorological science may be investigated; but such institution should have nothing to do with the daily weather service and issue of forecasts.' Duties connected with the latter services, according to the scheme, are to be entrusted to an official in each state."

Report on the climate and weather of Baltimore and vicinity, O. L. FASSIG (*Md. Weather Serv. Spec. Pub., 2 (1905), pt. 1b, pp. 145–310, pls. 12, figs. 47*).—This is a second section of the report on this subject (E. S. R., 16, p. 1058) and completes the part dealing with climate. The second part of the report is to deal with the weather of Baltimore and its vicinity.

Data based on observations by the U. S. Weather Bureau and U. S. Army Medical Department on humidity, precipitation, sunshine and cloudiness, winds, and electrical phenomena are summarized. Diurnal, annual, and irregular variations are considered. The general character of the season is shown graphically by a series of diagrams, "in which eight selected factors, expressed as departures from the normal climatic conditions at Baltimore, are presented for each season and year from 1871 to 1904." A brief account is given of the instrumental equipment and the history of observations of the Maryland Weather Service.

The mean precipitation for 1871–1903 was 43.34 in., the heaviest monthly rainfall being in July and August (4.66 and 4.20 in., respectively) and the lowest in October and November (2.99 in.). The average number of rainy days was 131. The heaviest rainfall occurs in spring and summer, the lightest in fall and winter.

Meteorology [of Tunis], winter of 1904–5, G. GINESTOUS (*Bul. Dir. Agr. et Com. [Tunis], 9 (1905), No. 35, pp. 304–315*).—A summary of observations on pressure, temperature, rainfall, evaporation, humidity, etc., at a large number of stations in different parts of Tunis.

On the cyclonic distribution of rainfall, J. A. UDDEN (*Augustana Libr. Pubs., No. 4, pp. 21, figs. 10*).—A series of observations on the occurrence of precipitation or cloudiness at Davenport, Iowa, with reference to the position of the center of the cyclonic area at the time of the observations is recorded and discussed, and results are platted on charts.

It was found that precipitation was most frequent at this point when it was to the west of the central low and most infrequent when it was to the southeast of the center. "From this distribution of precipitation it is evident that if forecasts were made on the supposition that precipitation is greatest on the southeast side of the central low, a large percentage of the predictions would announce the stormy weather ahead of time. For it would often happen that the center of the low would have to move east some two or three hundred miles before it would bring up that tract, where rains and snow are actually most frequent."

A similar study of data for other regions of the United States (the southwest plains, the Northwest, the upper Missouri valley, and Detroit and Buffalo) shows "clearly that the area of the greatest rain and snowfall is not in the same position with regard to the centers of low areas in different climatic regions. In every case it is eccentric and lies to the west, northwest, north or northeast, in the cases studied, but in no instance to the southeast."

The influence of eclipses on the movement of the atmosphere, W. DE FONVIELLE and P. BORDÉ (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), No. 13, pp. 901, 902*).—Discusses Clayton's work on this subject published in Memoirs of Harvard College, Vol. XLIII.

The pioneer forecasters of hurricanes, W. M. DRUM (*Havana, Cuba: Observatory of Belén, 1905, pp. 29*).—A brief review of the meteorological work of the Observatory of Belén in Havana, especially with reference to the forecasting of hurricanes in which, it is claimed, this institution was the pioneer.

Lunar influences, C. FLAMMARION (*Bul. Mens. Off. Renseig. Agr. [Paris], 4 (1905), No. 8, pp. 948–950*).—The results with peas, beans, beets, carrots, leeks, onions, potatoes, and other vegetables planted in different phases of the moon were inconclusive as to the influence of lunar radiation on vegetation. The observations are to be continued through a series of years.

On the influence of climatic factors on the development of plants, V. IVANOV (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 6 (1905), No. 1, pp. 11–23*).—The author points out that in interpreting the results of their studies on the influence of any climatic factor (light, heat, or humidity) on the yield, investigators as a rule base their conclusions on a comparison of the curves of the changes of the factor under consideration with the curves of the changes in yields, the remaining factors being ignored. Such a method can hardly be considered as scientific and does not give positive results.

The author describes a method which, in his opinion, is more reliable. This is based upon a consideration of observations on all climatic factors—mean temperature, precipitation, humidity of the air, soil moisture, hours of sunshine, etc.—during a number of years, compared with the total yields for the same period, as well as the increase in weight of the plants during certain intervals of time. It is also of importance to know the normal rates of increase of weight of plants at different stages of growth under controlled conditions as determined in laboratory experiments.—P. FIREMAN.

Investigations on the chemical composition of atmospheric precipitation as dependent upon meteorological factors, A. POSNJAKOW (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 5 (1904), No. 6, pp. 740–788; abs. in Centbl. Agr. Chem., 34 (1905), No. 5, pp. 289, 290*).—Systematic studies of the chemical composition (nitrous acid, nitric acid, ammonia, and sodium chlorid) of atmospheric precipitation, made at the magnetic-meteorological observatory of the University of Odessa during the period from April 1 to December 31, 1903, are reported.

The investigations included also studies of the influence of the direction and velocity of the wind on the frequency, amount, and composition of the rain, snow, dew, frost, etc. Dews were most frequent preceding a rainy period, but the heaviest dews followed such periods. The larger proportion of the dews occurred when the

velocity of the wind was from 4 to 5 meters per second, although the heaviest dew was observed when the velocity of the wind was from 5 to 6 meters per second. The average chlorin content of the precipitation was 17.9 mg. per liter, of ammonia 0.9 mg. per liter, nitric acid 0.8 mg. per liter.

The content of nitric acid as well as ammonia declined as the length of the rainy period increased. Thunderstorms exerted no influence on the composition of the precipitation. The ammonia content was higher after periods of drought. Precipitation which occurred during a sea wind contained the smallest amounts of ammonia and nitric acid; that which occurred during a wind from the direction of the town contained the largest amounts. The highest ammonia content was observed with a wind velocity of 46 meters per second; the maximum nitric acid content with a velocity of 3 to 5 meters per second.

Dew, frost, etc., contained nearly 2½ times as much ammonia, a correspondingly smaller amount of nitric acid, and a relatively larger amount of chlorin than rain, snow, etc. They also almost always contained some nitrous acid. The variations in the ammonia content of dew, frost, etc., depending upon the direction of the wind, were similar in character to those observed in case of rain, snow, etc., and as in the case of the latter, the composition of the dew, frost, etc., was not affected by thunderstorms. An increase in the velocity of the wind during precipitation resulted in a lowering of the ammonia content.

It is estimated that during the whole period of observation the precipitation carried down to the soil 1.22 lbs. of combined nitrogen per acre. The precipitation richest in nitrogen occurred during the warmest months, July and August.

The amounts of nitrogen as ammonia and as nitric acid, and of chlorin in the rain water collected at Rothamsted, N. H. J. MILLER (*Jour. Agr. Sci., 1 (1905), No. 3, pp. 280-303*).—This is a detailed summary and discussion of data relating to this subject, which have been more briefly reported elsewhere (E. S. R., 16, p. 856). In addition to the full tabulated data, a bibliography of 125 references to literature relating to the composition of atmospheric precipitations is given.

Nitrous acid in sea water, E. BÖDTKER (*Chem. Ztg., 29 (1905), No. 73, p. 956*).—Determinations by means of the Natterer iodin-zinc-starch solution or Greiss's reagent showed 0.002 to 0.01 mg. of nitrous acid (N_2O_3) per liter of sea water taken at Dröbak Biological Station on Christiania Fiord. This is about as much as the author found in rain water and makes it questionable whether nitrous acid generally plays any part in the nitrogen absorption of sea plants.

Neolithic dew ponds and cattle ways, A. J. and G. HUBBARD (*New York: D. Van Nostrand Co., 1905, pp. XII+70, figs. 25*).—This book is interesting as showing how a primitive people solved the problem of securing a water supply in their hill settlements where springs and streams were not available. The thermodynamics of the dew ponds, which condensed and collected the moisture of the air, is explained.

Recent progress in matters of water supply and sewage disposal, G. W. FULLER (*Jour. Amer. Med. Assoc., 45 (1905), No. 15, pp. 1059-1065*).—A paper read in the section on hygiene and sanitary science of the American Medical Association, at the fifty-sixth annual session, July, 1905, discussing the use of copper sulphate for purification of water supplies and reviewing progress in purification of water by sedimentation, filtration, etc., in water-supply control, and in disposal of sewage (by dilution, filtration, and septic treatment). The sewage pollution of oysters and other shellfish is also referred to.

A contribution to the study of the purification of waste waters of towns and of industries, A. CALMETTE, E. BOULLANGER, and E. ROLANTS (*Ann. Inst. Pasteur, 19 (1905), No. 9, pp. 529-540*).—The methods used and results obtained in a series of studies of the rate of destruction of the organic impurities of sewage by anaerobic fermentation in septic tanks are reported.

It was found that about half of the carbon of the sewage disappeared during 14 days, part in form of gas and part deposited in insoluble form. During the same period about 64 per cent of the organic nitrogen disappeared, but the amount of ammoniacal nitrogen increased, the total loss of nitrogen being about 8 per cent. A study of the relative rate of decomposition of the solid matter of the sewage in covered and uncovered tanks showed very slight differences as regards the efficiency of aerobic and anaerobic fermentation in dissolving the solid matter.

SOILS—FERTILIZERS.

The gist of four years' soil investigation in the Illinois wheat belt, C. G. Hopkins, J. H. Pettit, and J. E. Readhimer (*Illinois Sta. Circ. 99, pp. 4*).—The sources of supply of nitrogen, potassium, and phosphorus for wheat crops grown on the soils of this region are described, and the results of 4 years' experiments with different fertilizers, showing a profit only in case of applications of commercial phosphates, are briefly summarized.

The gist of four years' soil investigation in the Illinois corn belt, C. G. Hopkins, J. H. Pettit, and J. E. Readhimer (*Illinois Sta. Circ. 100, pp. 4*).—The sources of supply of nitrogen, potassium, and phosphorus for corn crops grown on the soils of this region are described, and the results of 4 years' experiments with different fertilizers, showing a profit only in case of applications of commercial phosphates, are briefly summarized.

Contribution to the solution of the question of the water content of the soil and the water requirements of plants, C. von Seelhorst and Müther (*Jour. Landw., 53 (1905), No. 3, pp. 239–259*).—This is an account of a continuation during 1904 of similar work carried on in previous years (E. S. R., 16, p. 856) and records results of observations on soils under oats, clover, and bare fallow in large cylinders (1½ cubic meters contents) sunk in a trench and so arranged that they can be weighed at regular intervals. In case of the oats the surface soil of one cylinder was kept stirred between the rows, while that of a second cylinder was compressed by rolling.

A detailed record is given of the rainfall, the hours of sunshine, and temperature of the air and soil, as well as of the changes in weight of the cylinders. The total rainfall during the period of growth of the oats was 109.8 mm. Of this, all was evaporated except 20.8 mm. in the case of the cultivated soil and 30.4 mm. in the case of the rolled soil. Of the 67.9 mm. of rainfall received by the clover up to the time of the first cutting, 47.2 mm. was evaporated.

The water requirements of both oats and clover were very much in excess of that supplied by rainfall during the growing season, hence the water supply of the soil derived from previous winter rains was drawn on. In case of oats grown on cultivated soil, 1 gm. of dry matter required 256.7 gm. of water, on rolled soil 270.2 gm. While the absolute amount of water required in case of oats grown on rolled soil was smaller than that of oats grown on cultivated soil, the relative amount was larger, due to the smaller yield on the rolled soil.

This lower yield on rolled soil is ascribed to poorer aeration, resulting in slower transformation of plant food and interference with root transpiration and not to lack of water. One gram of dry matter in the first cutting of clover required 423 gm. of water, in the second cutting 1,124 gm. There was very little drainage water in case of the cropped soils, and the loss of nitrogen in this way was very small, 6 kg. per hectare (5.34 lbs. per acre) under oats and 11.8 kg. per hectare (10.51 lbs. per acre) under clover. The amount of drainage water from the bare soil was much larger and the loss of nitrogen in this way was 60 kg. per hectare (53.44 lbs. per acre).

The hygroscopic capacity of soils, C. M. Luxmoore (*Jour. Agr. Sci., 1 (1905), p. 3, pp. 304–321*).—This article reports laboratory studies of the capacity of soils to

retain moisture in equilibrium with the atmosphere as influenced by proportion and character of organic material, relative proportions of mineral particles of different sizes, chemical and physical nature of mineral constituents, and temperature and humidity of the atmosphere. The studies were made with fine earth passing a sieve with meshes 3 mm. in diameter.

A mathematical exposition is given of the bearing of the analytical data on the first three factors named, and two series of experiments are reported. In the first of these "a number of small weighing bottles were prepared, containing respectively a gram each of five different soils and of their six fractions. These were put under a bell-jar, together with a dish which contained during most of the experiments a solution of calcium chlorid of which the concentration was determined when the bottles were removed for weighing; at the conclusion of the series the dish was filled with granular calcium chlorid in order to obtain the weight of the samples in equilibrium with a dry atmosphere. The water lost at 95° and the loss on ignition were also found, but all results are calculated to the weight of the material dried in this manner in the cold."

In order to overcome irregularities in individual figures observed in the first series, "the second series of experiments was extended over a greater number of observations, and more duplicates were used. The standard weights attained in a cold, dry atmosphere were determined eight times, five times over granular calcium chlorid, and three times over fused caustic potash, and the results obtained were in most cases in satisfactory agreement."

The more important conclusions reached are that "the organic substance not only has a powerful direct influence in attracting moisture, but it also acts indirectly, so that the joint effect of the organic substance and the surface of the mineral particles is not merely an additive property. The organic material probably serves to keep the finer grades of mineral matter apart and free to exercise surface attraction far more effectually than the coarser mineral particles are able to do. It appears that the organic substance in different fractions has not always the same hygroscopic power. . . . Mineral particles of the same size in different soils have not identical hygroscopic power. . . . The finest grade particles, especially the clay fraction, show specially high attraction for water in atmospheres of extreme moistness. . . .

"It follows from the foregoing that the attraction of mineral particles for moisture can not be strictly expressed as simply proportional to their surface, and it is readily seen that many apparent irregularities in the tables are due to the causes [noted above]. But within certain limits as to moisture in the atmosphere, and in spite of the disturbing influence of other factors such as the varying attraction of the organic material, its indirect action, and the special hygroscopic action of iron oxid and perhaps other soluble minerals, there is a regularity in what is here called the moisture multiple, so that it tends to assume a value inversely proportional to the diameter raised to the two-thirds power. . . .

"It appears as if the use of the two-thirds power ratio was most suitable for the majority of cases, but in the case of the finest particles in a very moist atmosphere the increase in moisture gained proceeds at a far higher rate."

The moisture of the soil in the climate of Tunis, F. Bœuf and Tourniéroux (*Bul. Dir. Agr. et Com. [Tunis], 9 (1905), No. 35, pp. 286–303, fig. 1, chart 1*).—A large number of determinations of moisture in cultivated and uncultivated soil and during different seasons (rainy and dry) of the year ended June 30, 1904, are summarized.

In the soils studied the moisture varied from 4 to 20 per cent. In soil which had been dug up to a depth of 0.15 meter (5.91 in.) the moisture varied from 8 to 20 per cent, in soil which had been cultivated after removal of the crop of wheat the variation was from 5 to 15 per cent, and in uncultivated soil 5 to 18 per cent. The improvement of the capacity of the soil for storing and retaining water by digging was quite

marked. On the other hand, light cultivation of the surface soil appeared to hasten drying out. The evaporation from the uncultivated soil was about the same as from that lightly cultivated, but it showed the advantage of absorbing more water in winter.

Oxidation in soils and its connection with fertility, E. J. RUSSELL (*Jour. Agr. Sci., 1 (1905), No. 3, pp. 261-279, figs. 2*).—Previous studies by Dehérain, Demoussy, and Wollny on oxidation in soils have been based on measurements of the carbon dioxid produced by soil kept at constant temperature in a given volume of air. The author reports studies based upon measurements of the actual oxygen absorbed.

The apparatus used consisted of "a flask of about 100 cc. capacity with two tubes sealed into its neck. One of these (*A*, fig. 1) is bent at right angles and terminates in a bulb *B;* higher up is the narrower one, *C*, of about 4 mm. diameter, also bent at right angles, but open at the end. A weighed quantity of the air-dried soil is introduced into the flask, a definite amount of water is added, and the neck of the flask is either sealed up or closed with a very well-fitting rubber cork. Potash solution (1 KOH : $2H_2O$) is run into *B* by the little side tube *D*, which is then sealed, and the end of *C* is dipped under mercury, thus converting it into a gage. The apparatus is now placed in a water-bath at constant temperature, oxygen is absorbed, and doubtless a complex reaction takes place, but the only gas likely to be set free from ordinary soils is carbon dioxid, and this is so rapidly absorbed by the potash that at any given moment the quantity present in the first state is negligible.

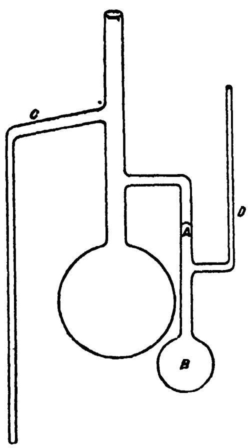

FIG. 1.—Apparatus for measuring the oxidation of soils.

"The absorption of oxygen is indicated by the rise of mercury in *C*, and from a measurement of the height of the column above the surface the amount of oxygen taken up is readily found. A cathetometer and millimeter scale are used for this purpose."

By this means the author studied the relation of various factors, such as quantity of soil, moisture content, lime and calcium carbonate content, horizon of soil (surface soil or subsoil), sterilization, and age of samples to oxidation. The rate of oxidation in a number of soils of known but varying fertility was also investigated.

The significance of the results is somewhat fully discussed and the following conclusions are drawn:

"(1) The rate at which oxygen is absorbed by a soil can be easily and accurately measured by the method here described.

"(2) The rate increases with the temperature, the amount of water (up to a certain point), and the amount of calcium carbonate, and is favored by the conditions obtaining in the surface soil as opposed to those in the subsoil.

"(3) These are also the conditions favoring fertility. It is found that with different soils of the same type the rate of oxidation varies in the same way as the fertility, and may be used to measure it. Pasture soils are at present excluded, however.

"(4) It is suggested that the oxygen absorbed measures the total action of the micro-organisms, which, by producing enzyms and in other ways, hasten decomposition in the soil. Plant food is thus produced, and the general conditions are rendered more favorable for plant life. Ceteris paribus, the more rapid these changes the more productive the soil will be."

On the fixation of ammoniacal nitrogen by zeolites in the soil, T. PFEIFFER and A. EINECKE (*Mitt. Landw. Inst. Breslau, 3 (1905), No. 2, pp. 299-310*).—Experiments were made with barley grown in glass vessels holding about 4,000 gm. of sand to

which was added 100 to 300 gm. of a zeolite prepared by mixing cement, fine-ground silica, and ocher, allowing the mixture to harden under water, grinding to a fine powder, and extracting with calcium chlorid and sodium chlorid solutions and water. The material thus obtained is designated a potassium-sodium-calcium zeolite. Superphosphate and ammonium sulphate were also applied. Data showing the balance of nitrogen in soil, fertilizers, and crops are reported, for soils receiving zeolite and those not so treated. The results indicate that the fixation of nitrogen by the zeolites was greater than the loss of ammonia due to the addition of calcium carbonate.

A new apparatus for the determination of ammonia absorption by soils, WOHLTMANN and P. SCHNEIDER (*Chem. Ztg., 29 (1905), No. 60, pp. 810, 811; abs. in Chem. Centbl., 1905, II, No. 8, p. 650*).—A graduated tube surrounded with a cooling mantle is filled with mercury, the mercury is partly replaced by dry ammonia cooled to 15° C., and a pellet of the soil is introduced into the tube through the mercury at the bottom of the tube. The absorption of ammonia is measured by the change in height of the mercury in the tube. The apparatus used is a modification of that devised by Hilgard for similar purposes.

The direct solution of the silicates of the soil and the experiments of Daubrée, L. CAYEUX (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 11, pp. 509, 510*).—The contention of Delage and Lagatu (E. S. R., 17, p. 226) that the mineral constituents of the soil—feldspars, etc.—are directly dissolved and so made available to plants and are not decomposed is refuted, as is the claim that the work of Daubrée[a] supports such a conclusion.

Agricultural charts, J. GRAFTIAU (*Ann. Gembloux, 15 (1905), Nos. 1 pp. 11–18; 2, pp. 57–63; 4, pp. 196–204; 5, pp. 260–266*).—A discussion of the nature and value of such charts.

Soil fertility, J. B. DANDENO (*Pop. Sci. Mo., 67 (1905), No. 7, pp. 622–625*).—In this article various factors of soil fertility are discussed and an attempt is made to show that soil fertility "is not so much a chemical as it is a physical, bacteriological, and ecological problem."

The microscopic world and agriculture, L. GRANDEAU (*Ann. Sci. Agron., 2. ser. 10 (1905), I, No. 3, pp. 450–473*).—After general notes on micro-organisms, this article discusses the reproduction, multiplication, and nutrition of micro-organisms, the bacterial population of the soil, and nitrification and the nitrifying organisms. The transformation of organic nitrogenous matter first into ammonia, then into nitrites, and finally into nitrates is traced.

Suggestions concerning legume inoculation, L. T. CLARK (*Michigan Sta. Bul. 231, pp. 223–230*).—The history of investigation relating to this subject is briefly reviewed, the practical possibilities of soil inoculation are discussed in a popular way, and methods of preparing pure cultures and studying the inoculating organisms are described.

Experiments on the action of lime nitrogen, E. HASELHOFF (*Landw. Jahrb., 34 (1905), No. 3–4, pp. 597–616, pls. 2*).—The preparation of this material is briefly described and previous experiments to determine its agricultural value are reviewed.

The experiments here reported were made during 1903 and 1904 at the Marburg station, and included investigations on the influence of the lime nitrogen on the germination of seeds and on the fertilizing value of the nitrogen in the material as determined in pot and field experiments. The germination experiments were made with clover and mustard seed in soil and sand to which lime nitrogen was added at the rate of 0.025, 0.05, and 0.1 per cent.

The results obtained were not uniform, but indicated in general an injurious effect of the lime nitrogen on germination, the injury being lessened or entirely prevented in dependence upon the length of time the material was applied before

[a] Étude synthétique de géologie expérimentale, 1879.

planting the seed. The injurious effect was greater in sand than in soil and with mustard seed than with clover seed.

In case of the soil, the addition of 0.05 per cent of lime nitrogen did not injuriously affect either the clover or the mustard seed when they were planted 8 days after the application of the material, while in sand the germination of clover seed was slightly interfered with even when planted 14 days after the application of the lime nitrogen, and when planted at an earlier period germination was entirely prevented. With mustard seed germination was reduced fully one-half even when planting was done 28 days after the application of the lime nitrogen. The same conditions were observed with the larger applications of lime nitrogen, only the injurious effects were more marked.

Pot experiments with mustard on a sandy loam soil to test the relative fertilizing value of lime nitrogen and nitrate of soda, and with carrots to determine the effect of adding lime to the nitrogenous fertilizers, are reported, as well as field experiments with rye and potatoes on light loamy soils and with barley, potatoes, and mangolds on heavier soils.

The general conclusions from the results of these experiments are that while lime nitrogen applied shortly before seeding injuriously affects germination, when the injurious constituents of the matèrial have had time to be transformed in the soil, the nitrogen serves as a plant food and possesses a value very nearly the same as that of the nitrogen of nitrate of soda. The time required for the decomposition of the injurious constituents of the lime nitrogen, however, varies with different kinds of soil, and until definite information on this point has been obtained the author advises that lime nitrogen should be used with caution and on a small scale in practice.

On the effect of ammonium salts on the assimilation of phosphoric acid by higher plants, D. N. Prianishnikov (*Ber. Deut. Bot. Gesell., 23 (1905), No. 1, pp. 8–17*).—The author briefly reviews experiments extending over several years, which show that ammonium salts, especially ammonium sulphate, exert an important influence in rendering the phosphoric acid of mineral phosphates available to higher plants, while sodium nitrate exerts no such influence. For this reason ammonium sulphate is designated "physiologically acid" and sodium nitrate "physiologically alkaline."

A series of sand and water cultures with barley, oats, buckwheat, flax, peas, and vetches to determine the status of ammonium nitrate with reference to acidity or alkalinity as thus defined is reported. The results show that this salt is intermediate in its action between ammonium sulphate and sodium nitrate and indicate that it may under certain conditions be physiologically acid. It was shown to increase the assimilability of the phosphoric acid of insoluble phosphates even in sterile cultures where nitrification did not occur.

Nitrate of soda as a fertilizer, M. Weitz (*Der Chilisalpeter als Düngemittel. Berlin: Paul Parey, 1905, pp. 492, pls. 8, figs. 228*).—This is a very complete treatise by the secretary of the Association of United Nitrate Producers on the occurrence and exploitation of nitrate deposits, the nitrogen requirements of soils and plants, the action of nitrate of soda on different kinds of plants as determined by experiments of various kinds, nitrate of soda as a means of protection against frost, plant diseases and enemies of various kinds, comparative value of nitrate and other forms of nitrogenous fertilizers, recent work on the fixation of the free nitrogen of the air, increasing yields by rational use of commercial fertilizers, the trade in nitrate of soda, and nitrate statistics.

Experiments with Lützeler meat guano, E. Haselhoff (*Landw. Jahrb., 34 (1905), No. 3–4, pp. 642–646*).—This material is a low-grade tankage treated with sulphuric acid and contains on the average 2 to 3 per cent of nitrogen and 1 to 2 per cent of phosphoric acid.

The results of the pot experiments with the guano in comparison with nitrate of soda and sulphate of ammonia indicate that the phosphoric acid is nearly as effective as that of Thomas slag and the nitrogen but slightly less effective than that of ammonium sulphate.

Experiments on the fertilizing value of mixtures of Thomas slag and steamed bone meal with kainit, E. HASELHOFF (*Landw. Jahrb., 34 (1905), No. 3-4, pp. 623-634, pls. 2*).—Pot experiments in 1902 and 1903 with wheat and barley are reported in detail.

Observations on the after-effects of the fertilizers and the influence of lime in connection with the other fertilizer mixtures are also recorded. The results show in general that the addition of kainit increased the effectiveness of the phosphoric acid in the case of both Thomas slag and bone meal. This was due apparently to the action of the kainit in rendering the phosphoric acid more readily available to the plant. The addition of lime in form of carbonate reduced the efficiency of the phosphoric acid in the bone meal to a marked extent.

Experiments on Thomas slag rich in silicic acid, E. HASELHOFF (*Landw. Jahrb., 34 (1905), No. 3-4, pp. 635-637*).—Comparative tests of Thomas slag poor in silicic acid and that in which the silicic acid had been increased by Hoyermann's process showed a somewhat lower efficiency of the latter.

Experiments with steamed Thomas slag, E. HASELHOFF (*Landw. Jahrb., 34 (1905), No. 3-4, pp. 637-641*).—Ground Thomas slag and that which had been reduced to powder by treatment with steam under pressure were tested in pot experiments with barley. The results show no marked difference in effect between the two forms of slag.

Potash salts, M. MAERCKER and M. HOFFMANN (*Die Kalisalze. Berlin: Deut. Landw. Gesell., 1905, 3. ed., pp. VII+61*).—This is the third edition of this treatise intended for the use of practical farmers. The second edition, published about 10 years ago, has been revised and brought up to date in this edition, which is published under the auspices of the fertllizer section of the German Agricultural Society.

On liming, O. LOEW (*Ztschr. Landw. Versuchsw. Oesterr., 8 (1905), No. 6, pp. 583-602*).—This article reviews quite fully recent investigations, including those of the author and his associates, on the use of lime as a fertilizer, concluding that the results confirm the author's well-known views regarding the necessity of maintaining a definite relation between lime and magnesia in the soil in order to insure the highest productiveness. It is also necessary that neither lime nor magnesia should fall below a certain limit. For this reason it is urged that in soil analysis determinations should always be made of the magnesia as well as of the lime.

Fertilizer suggestions, E. R. FLINT (*Florida Sta. Bul. 81, pp. 365-390*).—The formulas and suggestions contained in this bulletin are compiled from experiments made by the station in Florida and those of neighboring States. The fundamental facts underlying the use of fertilizers are discussed, the raw materials used in preparing fertilizers are described, and formulas for fertilizers for various field crops, fruits, and vegetables commonly grown in Florida are given.

Commercial fertilizers and chemicals, T. G. HUDSON ET AL. (*Bul. Ga. Dept. Agr., 1905, No. 42, pp. 205*).—This is a report on inspection of fertilizers on sale in Georgia during the season of 1904-5, including the text of the fertilizer laws of the State and miscellaneous information regarding fertilizers, as well as statistics by counties of the cotton crop of Georgia, 1900-1904.

Fertilizer analyses, A. J. PATTEN (*Michigan Sta. Bul. 232, pp. 23*).—This bulletin gives the text of the State fertilizer law, a list of dealers in fertilizers in the State, and analyses of 123 samples examined during 1905.

AGRICULTURAL BOTANY.

Experiments showing the effects of mutilation, or cutting, on growth, G. E. Stone (*Massachusetts Sta. Bul. 105, pp. 28–33*).—A series of experiments is reported which show the influence of mutilation of various kinds upon the growth of plants. The experiments were carried on with seedlings of sunflowers, broad beans, and lupines, as evenly paired plants as possible being selected and different lots subjected to mutilation by cutting the primary roots, splitting the primary roots, cutting the secondary roots, etc.

The effect of mutilation on growth, as shown in the experiments, gives some idea of the shock produced by this form of stimulation. The first effect is a disturbance of the normal activities of the plant, which, so far as growth is concerned, is more or less retarded. This is followed by an attempt of the organism to recover. The maximum period of retardation appeared shortly after cutting, and the maximum period of acceleration took place about 24 hours later. The degree of retardation and acceleration appears to be more marked in rapidly growing plants, or those that are more plastic, and is especially marked in the less differentiated cryptogams. In some of the lower organisms the retardation was so brief and the acceleration and growth so rapid that very close intervals in time of measurement were necessary to observe the effects of mutilation.

The experiments have a practical bearing in indicating the effect of pruning secondary organs on the growth of primary ones, and, conversely, the effect of pruning primary organs on the growth of secondary ones. The pruning of primary organs induces a marked stimulus to secondary organs and the pruning of secondary organs induces changes in the growth of primary organs. In the splitting of roots the injuries were of an insignificant character, since none of the essential organs were removed from the plant. By the destruction of the leaders of any terminal organ the normal geotropic irritability was interfered with, and mutilation of this character was sufficient to induce quick and decided responses. The degree of irritability or response to stimulation was more marked in secondary organs when the primary ones were cut, and vice versa.

The author concludes that "mutilation acts as a severe shock and sets the self-regulatory functions of the organism into activity, inducing a series of changes and responses which manifest themselves according to the nature, degree of intensity, and method of applying the stimulus, and they are also dependent upon the nature of the organism stimulated."

The effect of light and Bordeaux mixture on plants, R. Ewert (*Landw. Jahrb., 34 (1905), No. 2, pp. 233–310, pls. 3*).—The author carried on a series of experiments with potatoes to ascertain the effect of light and Bordeaux mixture on the physiological processes of the plant, the investigation being in part designed to test the claim of Schander (E. S. R., 17, p. 451) that the principal beneficial effect of Bordeaux mixture is to be attributed to the protective action that the film of the fungicide exerts on the chlorophyll of the leaf.

After briefly reviewing some recent literature relating to the subject, the author's experiments are described at length. These consisted of growing potatoes in pots under varying conditions of light and shade and with and without applications of fungicides. The effect of the varying degrees of light and of the presence of Bordeaux mixture on the yield of tubers, the starch and water content of the tubers, the foliage, etc., is described. It is said that the cultural and respiration experiments showed that the activity of the plant was reduced in direct proportion to the reduction of the sun's energy when cut off by the Bordeaux mixture.

In the practical use of fungicides the author thinks best not to recommend too complicated mixtures or those which are too expensive. Care should be exercised

in the preparation of Bordeaux mixture not to use iron sulphate in connection with the copper sulphate, as the iron compound not only weakens the solution, but increases its corrosive action. The use of too strong solutions is not to be advised, as they not only injure through their corrosive action, but retard the metabolism of the plant through the shutting off of the sunlight from the tissues of the leaves.

In this connection the author criticises the recommendation of Schander that 4 per cent solutions of Bordeaux mixture should be used on grapevines during bright seasons and weaker ones during cloudy seasons, as it is impossible to foretell what the entire season will be. The use of solutions stronger than those required to prevent fungus attacks is also liable to cause permanent injury to the vines by prolonging their growth late into the period when killing frosts may be expected. A 0.5 to 1 per cent solution of Bordeaux mixture will be found sufficiently strong for most cases.

The action of ether and chloroform on dry seeds, P. Becquerel (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), No. 15, pp. 1049-1052*).—On account of the difference of opinion regarding the action of ether and chloroform on dry seeds, the author has made a study of the subject, in which previous experiments have been repeated and a number of new investigations made.

A study was made of the effect of chloroform and ether in the liquid state. The seeds examined were peas, lupines, clover, alfalfa, and wheat, and they were divided into different lots, in one of which the seed coats remained intact, while in another they were perforated. One lot was in the ordinary condition of stored seed, while other lots were dried over chemicals until there was no further loss in weight. All were placed in chloroform and ether on March 24, 1904, and on March 22, 1905, they were taken from the flasks and spread upon filter paper to allow the liquids and vapors to evaporate.

They were then tested for germination, and the seed of the peas, alfalfa, clover, and lupine, whose seed coats remained intact, germinated after having been 363 days in the chloroform and ether. In all cases where the seed coat had been perforated the seeds lost their germinating power. In addition the wheat, the integument of which is permeable, was similarly affected. It seems that on dry seed, as long as the seed coats remain impermeable, the liquids and vapors of chloroform and ether are without effect.

The transformation of nitrogenous material during the ripening of seeds, G. André (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), No. 21, pp. 1417-1419*).—A study is reported on the changes in the total, albuminoid, and amid nitrogen, etc., of seeds of the white lupine during their ripening.

Vegetable albumin, which is present in the seed, disappears rapidly upon germination. Legumin is also present in the seed, but disappears after germination, reappearing and increasing in amount as the period of ripening advances.

It is shown that the transformation of a nitrogenous material during the ripening of the seed is the inverse of that which takes place during germination. Albumin appears late during the period of ripening and disappears very speedily after the beginning of germination. Legumin makes its appearance earlier during ripening and persists in the ripe seed in larger quantity than albumin.

The reserve carbohydrates of evergreen trees, Leclerc du Sablon (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), No. 24, pp. 1608-1610*).—The author has studied at different times of the year the reserve carbohydrates in the stem and roots of live oak, Austrian pine, and Japanese euonymus.

The carbohydrate content of the roots and stems of the live oak examined are shown in tabular form, and comparisons are made with similar examinations of chestnut stems and roots. In the case of the deciduous tree the maximum reserves were present at the end of October when the leaves were falling, and the minimum took place in the spring when the new shoots were being rapidly developed. In the

case of the live oak the maximum reserve was found in the spring of the year, while the minimum occurred in midsummer.

The Austrian pine gave similar results to those observed for the live oak, its maximum reserve being observed in May, after which there was a sharp reduction to a minimum in July. With the Japanese euonymus, whose growth begins early in the spring, the maximum reserve of carbohydrates was found to be in March, with the minimum in August.

The proteases of plants, II, S. H. VINES (*Ann. Bot., 19 (1905), No. 73, pp. 149–162*).—In continuation of the author's investigations on this subject, a report is given of experiments with papain from different sources and under different conditions.

In explanation of the action of papain two interpretations are offered, "(1) that a single protease is present, capable of both fibrin digestion and peptolysis, and that one or other of these activities may be more or less inhibited by the antiseptics, or (2) that two proteases are present in papain, which may respond differently and independently to the action of antiseptics." Of these two explanations the author prefers the second, which indicates that papain contains a fibrin-digesting protease of the nature of pepsin, and also a peptolytic protease of the nature of erepsin.

In continuation of other investigations (E. S. R., 14, p. 1051) the author has studied the proteolytic action of the foliage-leaves of various plants, and has added to the previous results, extending them to include the linden, rhubarb, and pokeweed (*Phytolacca decandra*).

The biology of Melanpyrum pratense, L. GAUTIER (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), No. 21, pp. 1414–1416*).—A note is given on the biology of *Melanpyrum pratense*, a plant which is shown to be semiparasitic in its habit of growth, attacking through mycorrhiza the roots of a number of forest trees and many grasses. It seems to prefer the beech as a host plant.

The bast cells of the hypocotyl of flax, A. HERZOG (*Separate from Ztschr. Farb. u. Textil Indus., 3 (1904), Nos. 20, 21, 22, pp. 15, figs. 20*).—The results of a microscopical study of the bast cells of the flax plant are given.

How to know wild fruits, MAUDE G. PETERSON, illus. by MARY E. HERBERT (*New York and London: The Macmillan Co., 1905, pp. XLIII+340, pls. 18, figs. 60*).—This book is intended as a guide to the identification of plants in the northeastern United States by means of their fruits and leaves.

Evolution of cellular structures, O. F. COOK and W. T. SWINGLE (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 81, pp. 26, pl. 1, figs. 2*).—A discussion is given of a number of factors that are believed to have a bearing on the evolution of plants and animals.

FIELD CROPS.

The book of the Rothamsted experiments, A. D. HALL (*London: John Murray, 1905, pp. XL+294, pls. 8, dgms. 49*).—This is a general account of the Rothamsted experiments intended for the use of the student of agricultural science as well as the practical man.

It summarizes the mass of information which has already been published in the long series of Rothamsted Memoirs, adding "other facts and deductions arising out of the experiments which the original investigators had not hitherto been able to publish." The author attempts to make the subject "plain to the nontechnical reader and to elucidate the subject by diagrams and simplified tables, leaving the specialist to consult the original papers for fuller information."

The book contains a biographical introduction, including obituary accounts by R. Warington of Sir John Lawes and Sir Henry Gilbert; chapters on the sources of nitrogen of vegetation, meteorological observations, the composition of the Rothamsted

soil, experiments upon wheat, experiments upon barley, experiments upon oats, experiments upon root crops grown continuously on the same land, experiments upon the continuous growth of leguminous crops, experiments upon grass land mown for hay every year, experiments upon crops grown in rotation, nitrification, and the composition of drainage waters, feeding experiments, and miscellaneous inquiries; and appendixes giving lists of publications issued from the Rothamsted Experimental Station, 1843–1905, publications by other investigators dealing with material from Rothamsted, and other publications dealing with the Rothamsted experiments, and present officials and past and present workers at the Rothamsted Experimental Station.

"In this book little has been said of the work now in progress; speaking generally, the old plats as described are being continued without essential change, but the current investigations deal chiefly with the composition of the crops produced and with the soil. The bacterial life of the soil forms indeed the unknown territory which promises the greatest reward to the explorations of the agricultural chemist of to-day."

The Woburn field experiments, 1903, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England, 65 (1904), pp. 288–306*).—The results here reported represent the twenty-seventh season of the experiments.

The plan of the experiments has been described in former abstracts (E. S. R., 16, p. 352). In alternate years, including this season, some of the plats received in addition to mineral fertilizers, ammonia salts, or nitrate of soda, in quantities furnishing the same amount of nitrogen as 100 lbs. of ammonia. In the continuous wheat-growing experiments the crop this season was considerably below the average. The unmanured plat produced 9.5 bu. of grain and 10 cwt. of straw. Nitrate of soda alone increased the yield to 16 bu., and an equal quantity of nitrogen in the form of ammonia salts where lime had been previously used gave practically the same results. Nitrate of soda and ammonia salts given in moderate amounts with the minerals gave nearly equally good yields.

Heavy applications of nitrogenous salts showed injurious effects, but the highest yield of the season, 34.1 bu. per acre, was secured where mineral manures and nitrate of soda, in quantities furnishing the same amount of nitrogen as 100 lbs. of ammonia per acre, were used. The yearly application of rape cake, equal in nitrogen value to 100 lbs. of ammonia, gave a larger yield of grain and straw this season than the annual use of barnyard manure furnishing twice the amount of nitrogen.

Lime applied with ammonia salts, alone or together with minerals, produced a marked beneficial effect on barley. The unlimed plats, although treated with nitrogenous fertilizers, either with or without minerals, produced practically no crop. The best yield, 41.6 bu., was obtained with a heavy dressing of nitrate of soda given together with minerals. With the light dressing of nitrate of soda alone only 10.2 bu. per acre were obtained. The barnyard-manure and rape-dust plats gave yields below the average. The barnyard-manure plat produced the best quality of grain. As in previous years, green manuring with mustard and rape gave larger yields than green manuring with tares.

Three Canadian wheats, Preston, Red Fife, and Percy, were grown as spring and winter wheats. Red Fife gave much better yields, and the fall-sown grain was much superior in quality to the spring-sown grain. As compared with average English varieties they were superior in quality, but did not rank with them in yield.

Among varieties of clover from different sources English and Chili red clover ranked first. Seed from Oregon and Indiana also gave good yields. In experiments to improve old pasture it was found that potash increased the clovers and that barnyard manure increased the yields but at the expense of the clovers, favoring to a greater extent the more vigorous grasses.

Spraying potatoes gave the same favorable results as in former years, while the use of lime almost entirely prevented finger-and-toe disease in swedes.

The Woburn pot-culture experiments, 1903, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England, 65 (1904), pp. 306–315, figs. 2*).

The Hills experiments.—In studying the influence of the iodids and oxids of manganese, potassium, sodium, and lithium on wheat the salts were mixed in the solid state with the upper 4 lbs. of soil in the pots.

The iodids were used at the rate of 1 cwt. per acre and the oxids at the rate of 2 cwt. The iodids of the 4 metals had an injurious effect, which was most marked in the case of the iodid of manganese (MnI_2). All the oxids had a beneficial influence on the growth of wheat, particularly the oxid of lithium. In the tests with barley all applications were made at the rate of 2 cwt. per acre. The iodids proved more injurious than in the experiments with wheat, while the oxids were neither harmful nor productive of a direct benefit.

The plants treated with lithium oxid were particularly healthful and vigorous, very broad-leaved, and well tillered. The results of water-culture experiments on barley with the iodids and oxids of manganese and lithium show that the iodids had an injurious effect on the root growth, being more marked as the strength of the solution increased. The oxids remained neutral. The manganese salts produced a thin, long, wiry root, and the lithium salts a thick, short, and stunted one.

Miscellaneous experiments.—From the results of a test with large and small kernels of barley for seed it is concluded that when the grains have good germinating power the smaller grains "are just as good or even better to sow than the large grains, and so long as the small grains are unbroken and sound there is no reason for considering their germinating power inferior to that of the larger grains."

[**Work with field crops**], J. S. COLE (*South Dakota Sta. Rpt. 1905, pp. 14–19*).—The report of the department of agronomy of the station for the year ended June 30, 1905. Brief notes are given on the experimental work in the rotation of crops and the adaptation and improvement of cereals, flax, and buckwheat. In connection with this work there were grown in 1904 230 varieties of wheat, 133 of barley, 95 of oats, 6 of rye, 5 of millet, 3 of buckwheat, and 3 of flax, and in addition nearly 600 selections were grown on plant-breeding plats.

Results of experiments conducted by the agricultural winter school at Frankenthal, V. RENNER (*Deut. Landw. Presse, 32 (1905), Nos. 51, pp. 435–437; 52, pp. 451, 452; 53, pp. 463, 464; 56, pp. 484, 485*).—Of 14 varieties of wheat Rimpau Bastard, Strube Squarehead, and Pfalz were best adapted to the region.

Pfalz is recommended for conditions of soil and rotation more or less unfavorable to the more productive varieties on account of winterkilling and summer droughts, while Strube Squarehead is considered suitable for farms on which winterkilling and summer droughts are not so likely to occur, and where soil and other conditions tend to produce heavy yields. Rimpau Bastard wheat was apparently suited to soils intermediate between those recommended for Pfalz and Strube Squarehead. This variety was found to require the use of high-bred seed from time to time for the purpose of maintaining its yielding power. The dry matter content of the grain was 87.83, 87.25, and 87.59 per cent, and that of protein 11.45, 9.99, and 11.15 per cent for Pfalz, Strube Squarehead, and Rimpau Bastard, respectively.

The results with rye indicated that Heine Improved Zeelander is best adapted to give good results with sufficient moisture, and that on very dry soils French Champaign gave the best results. Hannah rye seemed also well adapted to the dry soils, and has the advantage of ripening earlier and being less subject to lodging than French Champaign. On medium to light soils Petkus rye gave the best yields. Petkus is a high-bred variety, and under certain conditions subject to rather rapid deterioration, and for this reason the use of high-bred seed at certain intervals is recommended.

Third annual report of the Wisconsin Agricultural Experiment Association, R. A. MOORE (*Ann. Rpt. Wis. Agr. Expt. Assoc., 3 (1905), pp. 188, pls. 7, figs. 2*).—This report, compiled by R. A. Moore, secretary of the association, presents the

cooperative work during 1904 with soy beans, Swedish Select oats, alfalfa, and corn. Results with treating seed grain to prevent smut are also reported by a number of parties. The constitution and by-laws of the organization and the list of members for 1905 are given, and lessons in corn judging, with quite full discussions of the principal points, are outlined.

Agriculture in the North Central States, G. STIEGER (*Arb. Deut. Landw. Gesell., 1905, No. 104, pp. 70, figs. 25*).—Observations on farm management and farm life in the northern Mississippi Valley, mainly in Nebraska, Minnesota, and Wisconsin.

Agriculture without irrigation in the Sahara Desert, T. H. KEARNEY (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 86, pp. 30, pls. 5, fig. 1*).—The country known as the Oued Souf, situated in extreme southeastern Algeria, is described and its population, climate, water supply, soils, and date gardens are discussed.

The discussion on the date gardens includes descriptions of the methods of planting, care of the palms, and the harvesting of the crop. The manuring of the soil, the removal of the drifted sand from the gardens, the yields secured, and the varieties of dates chiefly grown are also considered. It is pointed out that in the Oued Souf, renowned for the large yields of its date orchards and the high quality of their fruit, the type of agriculture practiced is not dry land farming, as it depends upon the ground water, which in the gardens is everywhere near the surface of the soil.

It is further stated that the sand hills of the region concentrate and reflect so much heat that the hollows among them act as forcing houses in producing early dates. While the same conditions with respect to ground water may not be found anywhere in the United States, it is believed that the growing of dates in the hollows between the sand hills may be applicable to the hot arid regions of the Southwest, where large sand dunes exist, and where water for irrigation is available. "It seems certain that in pockets of this character excavated among the dunes the Deglet Noor and other valuable varieties of dates could be forced to early maturity."

The ripening of grain, A. NOWACKI (*Deut. Landw. Presse, 32 (1905), Nos. 57, pp. 491, 492; 59, pp. 505, 506*).—The author concludes from numerous experiments made at different times that the uneven ripening of grain is largely due to lodging and abnormally heavy stooling.

The breeding of varieties resistant to lodging by virtue of the normal structure of the stem is recommended. Attention is called to the fact that in a normal or ideal stem the internodes from the lower to the upper one increase in length and decrease in strength, according to a definite law which gives to each internode the average length and strength of the one immediately below and the one immediately above it. The normal stem obtains the greatest strength and flexibility with the smallest quantity of material in its structure.

Grain is said to lodge when the law of the arithmetical average with reference to the internodes is disturbed. This usually takes place in the second internode above ground, when the length and the thickness of the individual cell walls as well as of the entire internode are not in the right proportion to the length and thickness of the first and third internode. To illustrate, the author states that if the length of the first, second, and third internode from below is 1, 12, and 23 cm., respectively, the proportion is normal, while in a case where the corresponding lengths are 5, 18, and 19 cm. the second internode is 6 cm. too long.

This law, applied to the 3 lower internodes, is considered very important in breeding. In selecting plants with reference to their stooling qualities the author advises the choice of individuals with 3, 4, or 5 equally strong stems, uniform in development, and heading, blossoming, and ripening at the same time.

It is stated that when the kernel of wheat, oats, barley, and rye has a decided yellow color and a cross section reveals no trace of green chlorophyll, the grain is ripe for cutting. Notes on the condition of grain at this stage are given.

Grass lands of the south Alaska coast, C. V. PIPER (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 82, pp. 38, pls. 4*).—This bulletin has been partly noted from a condensed report on the same subject (E. S. R., 17, p. 349). In addition to the matter previously published the population, markets, transportation, climate, garden products, and fuel supply are discussed, and land laws applying to Alaska are given.

Contribution to the knowledge of Argentinian grasses, T. STUCKERT (*An. Mus. Nac. Buenos Aires, 3. ser., 4 (1905), pp. 43-161*).—Descriptions are given of 179 species and varieties of grasses.

The seeds of the blue grasses, E. BROWN and F. H. HILLMAN (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 84, pp. 38, figs. 35*).—This bulletin treats of the production and handling of blue grass seed, and gives descriptions and illustrations of these seeds and their impurities.

The germination, growing, handling, and adulteration of blue grass seeds, E. Brown (pp. 9–14).—Commercial and hand-gathered seeds are described and the grades and quality of commercial seeds discussed. It is stated that the more careful dealers in Kentucky blue grass seed maintain a purity standard of from 80 to 90 per cent in the so-called "fancy" grade, which is based on the relative cleanness and on the bright appearance of the seed, and that the grade known as "extra-clean" or "extra-cleaned" consists of the cleanings from the fancy seed, the samples as offered usually containing less than 10 per cent of seed of light weight. The rougher uncleaned seed as passed through a feed cutter contains from 60 to 70 per cent of pure seed.

That the unadulterated fancy grade is usually of good quality is demonstrated by the fact that the 2,887 samples tested by the Zurich Seed Control Station from 1876 to 1903 gave an average purity of 86.3 per cent. Sixty-nine samples tested in the Seed Laboratory of this Department during the past year showed an average purity of 75.02 per cent.

Samples of Kentucky blue grass seed sent to the Seed Laboratory have contained from 30 to 50 per cent of Canada blue grass seed, which is the only kind used as an adulterant of Kentucky blue grass in this country. A sample of wood meadow grass (*Poa nemoralis*), which is sometimes adulterated with other species of Poa, contained 59.4 per cent of *P. pratensis* and 23 per cent of *P. compressa*. It is pointed out that the standard weight of a bushel of blue grass seed of any grade is 14 lbs., but that the actual weight varies from 6 to 8 lbs. for the extra clean to 27 lbs. or more for especially good samples of fancy recleaned seed.

Reports from the Zurich Seed Control Station show that the average germination of 3,069 samples of Kentucky blue grass seed tested from 1876 to 1904 was 65 per cent, while 908 samples of *Poa trivialis* showed an average of 72 per cent. As carefully cured seed will germinate from 80 to 90 per cent, the low percentage of germination in the commercial seed is considered due to the heating of freshly stripped seed thrown together in piles. Notes on the growing and handling of 9 different species of blue grasses are given.

Descriptions of the seeds of the commercial blue grasses and their impurities, F. H. Hillman (pp. 15–38, figs. 35).—This part of the bulletin furnishes the necessary information for enabling seedsmen and others to distinguish the different species. A comparison of the principal distinguishing characters of blue grass seeds is given in a table. Keys to the seeds of the more common species of Poa as found on herbarium specimens, and of commercial blue grass seeds after preparation for market, are outlined.

Yellow oat grass, D. FINLAYSON (*Aynsome Agr. Sta., Seed-Testing Lab. Farmers' Bul. 7, pp. 3, figs. 5*).—A brief description of yellow oat grass is given, with notes on the purity, germination, and weight of the seed. Directions and illustrations are given for the determination of wavy hair grass, one of the common impurities.

Tall oat grass, D. FINLAYSON (*Aynsome Agr. Sta., Seed-Testing Lab. Farmers' Bul. 8, pp. 3, figs. 7*).—The habits and value of tall oat grass are described and the purity,

germination, and weight of the seed briefly noted. Soft brome grass, rye seeded brome grass, and darnel are given as the more common impurities of tall oat grass seed.

Meadow fescue, D. FINLAYSON (*Aynsome Agr. Sta., Seed-Testing Lab. Farmers' Bul. 9, pp. 8, figs. 6*).—This grass is described and its value, together with the purity, germination, and weight of the seed, is briefly noted. The most common impurities in the seed are dock, soft brome grass, rye seeded brome grass, perennial rye grass, and velvet grass.

Report on the manuring of seeds hay, 1904, W. ALLAN (*Edinb. and East of Scot. Col. Agr. Bul. 5, pp. 21*).—The results of 21 different tests showed that nitrogen was the fertilizing ingredient most required for the crop, and that nitrate of soda gave a better result than sulphate of ammonia, while a mixture of the two gave a slightly better result than either alone.

The plat receiving 40 lbs. of nitrogen per acre, which was the largest quantity applied, gave the heaviest yield of hay and the best financial return. Nitrogen alone gave satisfactory results. Phosphates had but little effect, and potash affected the yield more than phosphates. A complete application gave the best yield and the best returns.

Composition of forage crops, S. TRETYAKOV (*Khozvain, 1903, No. 52; abs. in Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 1, pp. 102, 103*).—It is concluded that owing to a higher content of plant food, especially nitrogen, in the soil, with a dryer climate and a greater amount of sunshine the cultivated plants of southern Russia are generally richer in protein and ash than those grown in western Europe.—P. FIREMAN.

Trifolium incarnatum, D. FINLAYSON (*Aynsome Agr. Sta., Seed-Testing Lab. Farmers' Bul. 5, pp. 8, figs. 7*).—This is a popular bulletin giving a description of crimson clover with brief directions for its culture. The value of good seed is noted and some of the impurities commonly found in the seed are mentioned.

Adulteration of alfalfa and red clover seed, J. WILSON (*U. S. Dept. Agr., Office Sec. Circ. 14, pp. 2*).—A brief report on purity tests of clover and alfalfa seed bought in the open market.

Three samples of red clover seed contained from 10.55 to 26.85 per cent of yellow trefoil, this being the only adulterant, and in 19 samples of alfalfa seed the total adulteration ranged from 1.25 to 45.73 per cent. Of the samples of alfalfa seed one contained sweet clover, 7 bur clover, 3 yellow trefoil, and 8 bur clover and yellow trefoil together. The largest quantity of sweet clover found was 9.53 per cent; of bur clover, 16.86 per cent, and of yellow trefoil, 39.85 per cent.

Experiments with fodder beets in 1903–4, TOURNIÉROUX (*Bul. Dir. Agr. et Com. [Tunis], 9 (1905), No. 35, pp. 269–281*).—The experiments here reported were conducted at the Colonial Agricultural School of Tunis.

The seed was planted in December, and by February 15 the plants were in good growth. The roots began to form about the first of April and were large enough for consumption by May 15, when the lower leaves began to dry, and by August 15 all the leaves were completely dead. Four varieties were grown, ranking in decreasing order of yield as follows: Géante de Vauriac, Ovoide des Barres, Disette Mammouth, and Demi-Sucrière.

The results with commercial fertilizers indicated that during a dry year the fertilizer application remains practically without results. Barnyard manure always gave the best returns. Beets in rows 40 cm. apart gave a marked increase in yield over those in rows 50 cm. apart. The results indicated that, in general, planting in November brings much better yields than planting about a month later.

A study of the composition of the beets showed that the maximum dry matter content was reached in June, and that the proportion and quantity of sugar was subject to nearly the same variations as the dry matter. The author concludes that the

conditions of culture in Tunis are so different from those in France that the performance records of a variety in the two countries can not be compared.

Corn growing in Virginia, A. M. Soule (*Va. Dept. Agr. and Immig., Farmers' Bul. 4, pp. 31, figs. 20*).—Corn growing in Virginia is discussed, the total yield of the State compared with that of several other States, and the possibilities of improving the industry pointed out. Directions are given for the selection of corn and the growing of seed. The causes of poor yields and the influence of planting upon the yield are considered. Notes are given on a number of record crops grown within the State, and the cost of producing corn on an 8-acre tract of land under Virginia conditions is estimated.

The production of good seed corn, C. P. Hartley (*U. S. Dept. Agr., Farmers' Bul. 229, pp. 23, figs. 10*).—This bulletin comments briefly on the general demand for well-bred seed corn and the need and importance of improved strains for different localities; describes more fully the important characters the stalk, ear, and kernel should possess, and outlines completely a method of corn breeding including the choice of a strain or variety, the selection of parent ears; the location, arrangement, and management of the breeding plat, and the selection of seed.

Directions for the care of seed corn and testing its germination are also given. Notes by H. J. Webber on the selection and care of seed corn when taken from the field instead of the breeding plat are appended.

Pedigreed seed corn, C. G. Williams (*Ohio Sta. Circ. 42, pp. 11, dgm. 1*).—A paper discussing the value of corn breeding, describing the arrangement of the breeding plat with directions for its management, and outlining a system by which pedigreed and certified seed corn may be produced.

Score card for dent corn (*Ohio Sta. Circ. 43, pp. 3*).—A score card for dent corn is given, with an explanation of the different points as they are applied in corn judging.

Cultivation of cotton on the Odessa Experiment Field, Rotmistrov (*Zeml. Ghaz., 1905, No. 9, pp. 364, 365*).—Experiments were made with American upland and Turkestan cotton. The American variety gave somewhat better results than the Turkestan.—P. FIREMAN.

Fertilizer experiments with hops near Saaz, A. Mahner (*Deut. Landw. Presse, 32 (1905), Nos. 52, pp. 452–454, figs. 5; 53, pp. 465, 466*).—The results of these experiments showed that the use of barnyard manure alone had no influence upon the development of the hop plant with reference to its structure, and that the commercial fertilizers were not injurious to the quality of the hops, as is contended by many producers.

A study of the lupulin content pointed out the importance of using a complete application of commercial fertilizers. Kainit when applied in the fall or winter was preferable to 40 per cent potash salt, while for spring applications the potash salt is recommended. Although barnyard manure was injurious to the proper development of the strobile and reduced the lupulin content, the author is of opinion that its use in hop culture is necessary for the maintenance of soil fertility, and that it is largely a question of when to apply it. The importance of barnyard manure in connection with hop culture is discussed, and a method of conducting fertilizer experiments in hop yards is described.

The peanut and its culture, W. N. Roper (*Petersburg, Va.: American Nut Journal, 1905, pp. 75, figs. 12*).—A brief treatise on the peanut industry of this country, giving directions for the culture of the crop and its preparation for market.

The injurious effect of crude potash salts on the potato, H. Süchting (*Landw. Vers. Stat., 61 (1905), No. 5–6, pp. 397–449*).—A series of pot experiments to determine the effects on the potato of magnesium, sodium and chlorin contained in crude potash salts is reported.

Sodium in the form of the carbonate had no injurious effect when 3.4 gm. of sodium oxid were supplied for every 19 gm. of soil. The plants containing the highest quantity of sodium at the period of most active growth gave the best yields, and the injurious effect of sodium chlorid independent of a general action of the salt is, therefore, considered due to the chlorin. When sodium salts were supplied the variety Daber took up more sodium, while in the other variety, Leo, no increase in this element took place. The application of sodium salts increased the quantity of potash used by the plants. During the most active growth the sodium is equally distributed throughout the plant, while at the close of the growing period it gathers in the parts above ground.

The difference between varieties in the degree of injury resulting from the impurities in the potash salts is ascribed to the difference in the nutritive effect upon the varieties of the potash furnished. The excess of chlorin in the leaves during growth, which resulted from the use of sodium chlorid, is partly transported to the tubers at the close of the vegetative period. The older variety, Daber, which sustained the greatest injury, retained more chlorin in its leaves than the newer variety, Leo.

The quantity of potash translocated in the leaves was also greater in the Leo than in the Daber variety. In either variety the application of sodium chlorid did not perceptibly impede the movement of potash from the leaves. Daber was better able to use the soil potash than Leo.

Influence of environment on the composition of the sugar beet, 1904, together with a summary of the five-year investigation, H. W. WILEY (*U. S. Dept. Agr., Bur. Chem. Bul. 96, pp. 66, pl. 1, charts 10*).—In 1904 the work was continued along the same lines as previously reported upon (E. S. R., 17, p. 457).

The seed used this season, grown at Fairfield, Wash., from Kleinwanzlebener mother beets exceptionally high in quality, germinated 169.5 sprouts per 100 seed balls. The best beets in so far as size is concerned were produced at Madison, Wis., and Geneva, N. Y., the topped beets weighing about a pound. Typical yields varying from 19.9 to 14.9 tons per acre were secured at Madison, Wis., Geneva, N. Y., and Agricultural College, Mich.

The beets produced in Michigan and Indiana contained about 15 per cent of sugar; those grown at Geneva, N. Y., and Blacksburg, Va., 13 per cent; at Ithaca, N. Y., and Madison, Wis., 12 per cent; and at Lexington, Ky., and Washington, D. C., 11 per cent. The beets from Madison, Geneva, Blacksburg, Lexington, and Agricultural College had a purity of over 81, while those from Washington, Lexington, and Ithaca ranged from 72 to 76 in this regard.

The stations having the highest temperature include Washington, D. C., Lexington, Ky., and Lafayette, Ind. The rainfall was greatest at Madison and smallest at Lexington, amounting to 22 and 13 in., respectively. The largest number of clear days occurred at Lexington and the smallest at Blacksburg. The percentage of sunshine was not obtained from all the stations, but the data reported gave Lexington the highest and Agricultural College the lowest.

The results obtained at 2 irrigated stations, Pomona, Cal., and Fort Collins, Colo., show a great superiority of the product at the Colorado Station, which is attributed largely to the low temperature at that point. The mean temperature for the growing season at Pomona was 8.6° higher than at Fort Collins. The precipitation at Fort Collins was almost as great as at Lexington. Pomona had nearly 3 times as many clear days as Fort Collins and 12.5 per cent more sunshine.

It is regarded as evident that the influence of latitude has 2 components, length of day and degree of temperature. Results obtained at Blacksburg indicated that the degree of temperature is by far the more important. In general the results show little relation between the hours of sunshine and the sugar content, and in this respect are entirely in harmony with those of previous years. The figures representing the content of sugar coincided, in general, with the purity of the juice and

the average length of day, and they show that there is a tendency to diminish the content of sugar by diminishing the hours of daylight.

The data further show that a high altitude may offset a low latitude in its relation to the sugar content, and they illustrated that the most depressing effects on the sugar content are produced by the combination of low altitude and low latitude. The conclusion is drawn that beets rich in sugar are most readily produced under favorable conditions combined with a high latitude and a high altitude.

A general summary of the data for the 5 years is given in the following table:

General averages of agricultural, analytical, and meteorological data from 1900–1904.

Station.	Number of years.	Estimated yield per acre.	Sugar in the beet.	Purity coefficient.	Meteorological data.			
					Temperature.	Precipitation.	Clear days.	Sunshine.
		Tons.	*P. cent.*		*°F.*	*Inches.*		*P. cent.*
Lexington, Ky	5	8.4	9.0	71.2	69.6	14.9	90	71.6
Washington, D. C	5	15.7	9.1	71.3	68.8	21.5	83	62.9
Blacksburg, Va	3	13.3	12.9	77.7	64.4	21.9	57	53.7
Madison, Wis	5	18.2	13.0	81.4	63.3	21.1	56	....
Lafayette, Ind	4	7.5	13.2	83.2	67.4	20.8	71	64.7
Ithaca, N. Y	5	13.3	13.2	79.0	62.1	18.8	48	60.4
Ames, Iowa	3	14.2	13.8	79.6	66.6	25.0	107	64.2
Agricultural College, Mich	4	13.4	14.2	83.6	62.3	19.8	63	59.6
Geneva, N. Y	5	16.1	14.6	85.1	64.0	20.0	....	....
Irrigation stations:								
Logan, Utah	3	18.9	13.2	81.2	62.1	5.9	126	78.7
Pomona, Cal	2	8.0	14.2	82.5	68.9	3.65	124	73.8
Fort Collins, Colo	3	20.4	14.7	83.9	59.4	11.0	80	63.8

The agricultural data show that in the 5 years the yields at Washington, Blacksburg, Madison, Ithaca, Ames, Agricultural College, and Geneva were in each case over 12 tons, while at Lexington and Lafayette approximately only a half crop was produced; and that at Raleigh, N. C., for 2 years the crop was practically a failure. The general proposition established by this series of investigations is that "temperature, or, in other words, latitude, is the most potent element of the environment in the production of a beet rich in sugar."

The results at the irrigated stations show that the predominating factor in so far as yield is concerned is the distribution of the water. It is also pointed out that the purity coefficient increases with the sugar content. The beets grown at Lexington were lowest in sugar and also lowest in purity, while those at Geneva with the highest sugar content were also highest in purity.

In studying the influence of rainfall it was observed that if its distribution or its deficiency produces a small crop of undersized beets, the percentage of sugar in the beet is incidentally increased, while a very abundant and well-distributed precipitation producing a beet of extraordinary size diminishes the percentage of sugar. The renewed growth of beets, due to a period of warm wet weather after they have reached a certain degree of maturity, also reduces the sugar content. It is concluded that the average data secured show no direct relation between the content of sugar in the beet and the number of clear days and percentage of sunshine.

In comparing the composition of the soil and the yield it is shown that the soil diminishes the sugar content when an overgrowth is produced by an excess of plant food, and causes an increase in sugar content to a slight extent when the amount of plant food is insufficient to produce a normal growth. The general conclusion from these and other experiments is that the soil and the fertilizers used have only a limited influence upon the actual sugar content, and that this influence was incidental rather to the vigor of growth than to any specific action on the sugar content itself.

The culture of sugar cane and the sugar industry in Hawaii and Réunion, L. Colson (*Paris: Augustin Challamel, 1905, 2. ed., pp. 431, figs. 26, maps 2*).—In discussing the culture of sugar cane, the soil, planting, use of fertilizers, irrigation, cultivation, yield, varieties of cane, rotation of crops, labor, cost of production, methods of transportation, experiment station work with sugar cane, and planters' associations are considered.

Descriptions of a number of plantations and sugarhouses are also given. Much of the information presented is compiled from bulletins and periodicals published in the Islands. The discussions on the manufacture of sugar treat of the methods and systems of machinery employed, the yields of sugar, uses and value of the by-products, and the cost of production.

Assimilation in the sugar-cane plant, Z. Kamerling (*Meded. Proefstat. Suikerriet West-Java, 1905, No. 81, pp. 9*).—The series of investigations here reported has been previously described and the results up to date have remained approximately as those previously reported (E. S. R., 15, p. 467).

Tobacco investigations in Ohio, G. T. McNess and G. B. Massey (*U. S. Dept. Agr., Bur. Soils Bul. 29, pp. 38*).—The climate of southwestern Ohio, the best tobacco soils of the region, comprising the Miami gravelly loam and the Miami clay loam, and the 4 principal varieties of tobacco grown in the Miami Valley, namely, Zimmer Spanish, Ohio seed leaf, Little Dutch, and Ohio Cuban, are described, and a report on growing Cuban seed tobacco and on the introduction of bulk fermentation in Ohio is presented. The work in the production and preparation of the crop in 1904 is described in detail.

The changes in temperature from November 21 to January 30 during the fermentation of a bulk containing 3,950 lbs. are tabulated. The changes in temperature of the bulk after "kasing," or adding water by artificial means, are also given. In the first bulk the temperature when allowed to run as high as the moisture in the leaf would admit did not go above 120° F. Early in February this bulk was taken down and rebuilt after each hand of tobacco had been dipped in water. Within 6 days the temperature had reached 121° F., when the tobacco was again taken down, shaken out, and rebulked. In this bulk the highest temperature, 120° F., was reached on February 25, after which the thermometer indicated a decline in the fermentation. After rebulking on March 1 the temperature did not rise above 109° F. and fell to 98° on March 31. When the tobacco was sized, graded, and rebulked to age the temperature averaged 102°.

A statement is given showing that the cost of growing Cuban seed tobacco in the experiment of 1904 was 10.5 cts. and the cost of fermenting and packing 4.5 cts. per pound. The tobacco lost in shrinkage about 13 per cent from the time it was cured to the time it was baled. Sixty-nine per cent of the crop was graded as heavy filler, 15 per cent as light filler, and 14 per cent as broken and trashy leaves. On the Miami clay loam 509 lbs. of leaf per acre and on the Miami gravelly loam 770 lbs. were secured. In experiments conducted in 1902, 2,191 lbs. of fermented tobacco was obtained from 6 acres of Cuban seed leaf. Five acres of Zimmer Spanish this same year yielded 748 lbs. per acre. In 1903, 7½ acres of Cuban seed tobacco on Miami clay loam yielded 3,950 lbs. of air-cured leaf, which weighed 3,451 lbs. when fermented and baled.

In December, 1904, the Zimmer Spanish was sold at 16½ cts. per pound, but the Ohio Cuban was not sold because the leaf was a little too heavy. Neither of these types of tobacco was up to the standard of quality, due to unfavorable climatic conditions. The Ohio Cuban grown in 1903 was sold at 35 cts. per pound, less 3 per cent for cash, giving a return for the finished product of $143.85 per acre.

Complete directions are given for fermenting in bulk, together with the details of fermenting different types of leaf. Changes in temperature of bulks of Zimmer Spanish, Ohio seed leaf, and Little Dutch are recorded. The Bureau introduced the bulk

method of fermentation in 1902, when 655,200 lbs. of Zimmer Spanish was treated by this method; in 1903, 4,212,000 lbs., and in 1904, 10,208,000 lbs., consisting of Zimmer Spanish, Ohio seed leaf, and Little Dutch, were fermented in bulk under its direction.

Experiments in growing Sumatra tobacco under shelter tent, 1903, W. FREAR (*Pennsylvania Sta. Bul. 72, pp. 11*).—Cooperative experiments in growing Sumatra tobacco under shade were conducted on two farms, one on Donegal gravelly loam soil and the other on Penn sandy loam. Similar experiments were made on the Donegal gravelly loam in 1902.

Notes on the weather conditions and the culture, harvesting, and curing of the crop are given, together with statements relating to the expense involved in the different operations. The crops were bulk-sweated with other Sumatra leaf, and graded according to the Connecticut standard. In the crop from the Donegal gravelly loam soil the loss from sweating and in rejected leaf amounted to 21.9 per cent. In the sweated crop 34.2 per cent of the leaves were graded as light-colored and 47.9 per cent as dark. Of the selected leaf 58.4 per cent was regarded as fit for wrappers. About three-fifths of the crop consisted of leaves over 16 in. in length.

The results so far obtained indicate that the shade-grown leaf on the Donegal gravelly loam, lacking in luster, life, and color, is not a satisfactory substitute for imported wrapper leaf, but that on the lighter Penn sandy loam a leaf of more acceptable color, better luster, and less flimsiness is obtainable.

Tobacco investigations in Porto Rico during 1903–4, J. VAN LEENHOFF, Jr. (*Porto Rico Sta. Bul. 5, pp. 47, pls. 5, fig. 1*).—This is the Spanish edition of Bulletin 5 of the Porto Rico Station, the English edition of which has been noted (E. S. R., 17, p. 32).

Improving the quality of wheat, T. L. LYON (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 78, pp. 120*).—This bulletin contains a historical and an experimental part.

The historical part consists of a brief summary of a number of experiments made from 1845 to the present time in this and other countries, and bearing on the influence of the time of harvesting, the use of immature seed, the conditions of soil and climate, the supply of soil moisture, and the size or weight and the specific gravity of the seed on the composition and yield of wheat.

The experimental part presents the results obtained by the author in breeding experiments conducted at the Nebraska Experiment Station in cooperation with this Department. The object of the investigations was to determine whether a high or low nitrogen content may be a characteristic of an individual plant, whether this quality is transmitted to the offspring, with what constant characteristics it is correlated, and whether a high percentage of nitrogen in a normal matured wheat plant indicates a large accumulation of nitrogen by that plant.

The data indicate that when grown under the same conditions kernels of the same variety high in proteid material have a lower specific gravity, weigh slightly less, and occupy a smaller volume than kernels having a smaller percentage of proteids. The same relations obtain between individual spikes and individual plants, but the relation of light kernel and high percentage of nitrogen did not appear to hold between individual plants in different years. As between kernels, spikes, and plants the kernels of greater weight contained a larger weight of proteids, although a lower percentage.

The quality of high proteid content and its correlated properties, it was found, may be due to immaturity in the kernel, or they may belong to the normal and fully ripened kernel. It was further shown that plants bearing either the largest number or the greatest weight of kernels as well as those producing the greatest weight of proteid matter and gluten have kernels of more than medium, but not the greatest weight.

Seed wheat separated into heavy and light seed and sown at the rate of 1½ bu. per acre produced much the larger crop from the heavy kernels, but only a small difference in yield resulted from selecting heavy seed from the crop grown from heavy seed, and light seed from the crop grown from light seed, during the 3 or 4 succeeding years. After the first year the light seed produced a greater amount of protein per acre than did the heavy seed. The 2 rows of spikelets in the head presented a fairly close agreement as regards the total or the proteid nitrogen content of the kernels, and the same was found to be true for one-half the number of spikes, as compared with the other half on plants with at least an average number of spikes.

The data also show that there may be quite a large variation in the proteid nitrogen content of different spikes on the same plant. That of 800 spikes of different plants of the same variety varied from 1.12 to 4.95 per cent, and 351 plants of the same variety the following year varied from 1.20 to 5.85 per cent. As the proportion of gluten to proteids in kernels of different wheat plants was found to vary considerably in certain cases, it is recommended that selection for improvement should be based on the determination of gluten. Plants with kernels high in gluten contain a smaller proportion of other proteids than plants medium or low in this constituent.

In wheat of the same variety grown under identical conditions, the relation of gliadin to glutenin was practically the same in plants varying largely in proteid nitrogen, and it is therefore assumed that an increase in the gluten content of a given variety raised in the same region would improve, on the average, its value for bread making.

The content of proteid nitrogen, the kernel weight, and the total proteid nitrogen production by the plant are considered hereditary qualities, and it is pointed out that plants possessing any of these qualities in an extreme degree show a tendency to produce progeny in which the same qualities approach more closely to the average, but that certain exceptional plants may transmit the same or more extreme qualities.

The yield of grain per plant was decreased in proportion to its susceptibility to cold, the effect of a severe winter being to reduce its tillering capacity. Early maturing plants, as compared with later maturing individuals, gave better yields, but the grain was slightly lower in nitrogen content and the number of grams of proteid nitrogen in the average kernel was also less. Plants with heads of slightly more than medium size produced the largest yields of grain and were taller than plants with either larger or smaller heads, while plants with heads of medium size, or slightly less, tillered most extensively. The weight of the average kernel did not increase or decrease with the size of the head, although on the very largest heads it was reduced. The largest yielding plants were the tallest and tillered most.

The variability of wheat varieties in resistance to toxic salts, L. L. HARTER (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 79, pp. 48*).—Experiments were conducted to study the effect of the harmful salts present in the so-called alkali soils of the West on the growth of wheat.

Varieties representing very different conditions of climate and soil were selected and a description of each is given. The seeds were germinated in sphagnum moss, and only seedlings having healthy and vigorous rootlets were used. When the radicles were from 3 to 4 cm. long the seedlings were taken out of the sphagnum and the tips of the roots immersed in the different salt solutions. After 24 hours they were taken up, the elongation of the rootlets measured and transferred to hydrant water, where they remained for another 24 hours. The radicles showing additional growth in the hydrant water over the growth in the salt solution were considered as having survived, and those making no additional growth as being dead.

Usually the experiments lasted about 10 days, and from 60 to 100 seedlings were used to establish the toxic limit in each case. The results are brought together in the following table:

Resistance of wheat varieties to various salts in terms of fractional parts of a normal culture.

Name of wheat variety.	Magnesium sulphate.	Magnesium chlorid.	Sodium carbonate.	Sodium bicarbonate.	Sodium sulphate.	Sodium chlorid.
Zimmerman	0.0075	0.015	0.0125	0.028	0.05	0.065
Kharkof	.00625	.01	.015	.03	.0425	.055
Padui	.0075	.01	.01	.0275	.045	.0575
Kubanka	.0075	.00875	.0075	.025	.05	.0575
Turkey	.01	.0075	.015	.0275	.0425	.05
Maraouani	.0075	.01	.008	.0225	.0475	.055
Budapest	.01	.0125	.005	.025	.0375	.0475
Preston	.005	.005	.0125	.025	.035	.055
Chul	.005	.005	.0125	.025	.04	.045
Average	.00736	.0093	.0109	.026	.0433	.0542

The ash constituents of the wheat seedlings were also determined, but no correlation between the amount or the composition of the ash and the resistance of the seedlings to saline solutions was established. The author compares some of his results with those obtained by other investigators in work with lupine and maize, as follows:

Differences in the toxicity of the same salts to wheat, lupine, and maize.

Salt.	Degree of concentration.					
	Wheat.		Lupine.		Maize.	
	Parts of a normal solution.	Parts per 100,000 of solution.	Parts of a normal solution.	Parts per 100,000 of solution.	Parts of a normal solution.	Parts per 100,000 of solution.
Magnesium sulphate	0.007	39	0.00125	7	0.25	1,400
Magnesium chlorid	.009	108	.0025	12	.08	384
Sodium carbonate	.01	52	.005	26	.015	78
Sodium bicarbonate	.026	217	.02	167	.05	417
Sodium sulphate	.043	302	.0075	53	.05	353
Sodium chlorid	.054	313	.02	116	.04	232

It may be observed from this table that while magnesium sulphate is the most toxic to the wheat and the lupine of all the salts used, it is the least injurious to maize.

It is shown that the ratio of resistance of one variety of wheat to another varies for different salts, being in general greater for the more toxic salts and smaller for those less toxic in their effects. The greatest ratio of resistance between varieties, 1:3, was observed in the tests with sodium carbonate and magnesium chlorid. In the magnesium sulphate tests this ratio between the most and the least resistant varieties was 1:2. The average resistance of a variety was not correlated with its resistance to the different individual salts.

It is pointed out that a variety averaging least in resistance may be much more resistant to a particular salt than the variety averaging highest, and that this fact may be of value in selecting varieties for soils containing an excess of some one salt. Varieties from localities where toxic salts are abundant in the soil are most resistant in water cultures to these salts, while those from humid regions are less resistant. Individual variation makes the establishment of the toxic limit in some varieties more difficult than in others. In all cases the resistance of a variety must be worked out for itself.

All the salts used, except sodium carbonate and sodium chlorid, acted as stimulants, the elongation in some cases being twice that occurring in hydrant water. It was

found that absolutely pure distilled water does not hinder development, but that traces of zinc are sufficient to kill the root tips in 24 hours. It is believed that water culture experiments may be a means of saving several years of selection by indicating whether a variety is adapted to soil conditions in a particular region.

Cultivation of wheat at the Bathurst Farm, R. W. PEACOCK (*Agr. Gaz. N. S. Wales, 16 (1905), No. 5, pp. 455–459, fig. 1*).—The cultivation of wheat at the farm is described and the results with a list of varieties reported. Among 11 varieties Tarragon and Cleveland led in productiveness, with yields of 38 bu. 43 lbs. and 36 bu. 21 lbs. per acre, respectively.

Cultivation of wheat at Glen Innes Experimental Farm, R. H. GENNYS (*Agr. Gaz. N. S. Wales, 16 (1905), No. 5, pp. 459–462*).—Wheat was grown at this station at an elevation of over 3,000 ft. and with a rainfall of 14.5 in. during growth. The varieties leading in yield were Sussex, with 34.26 bu., and Tardent Blue, with 30.5 bu. per acre.

The position of the wheat grains in the head in relation to seed selection, J. ADORJÁN (*Ztschr. Landw. Versuchsw. Oesterr., 8 (1905), No. 6, pp. 609–628*).—The results of the investigation here reported show that the heaviest kernels stood lowest in mealiness and highest in protein content. In connection with these qualities these grains also ranged first in specific gravity, and the author points out the value of this fact in selecting them for seed by means of centrifugal force.

From the data obtained the author concludes that the third or fourth kernel in the spike, counting from below, is the heaviest and probably also highest in specific gravity, and recommends therefore that these kernels be selected for seed.

The quality of the seed in its relation to the yield of wheat, J. ADORJÁN (*Ztschr. Landw. Versuchsw. Oesterr., 8 (1905), No. 6, pp. 629–632*).—The results of an experiment with selected seed, conducted in duplicate, show that the seed representing the fourth kernel from the lower end of the spike produced the largest yield, and that the productivity of the seed decreased as the kernels were taken higher or lower in the head.

Variety tests with winter rape, T. REMY (*Deut. Landw. Presse, 32 (1905), No. 54, p. 472*).—Seven varieties were drilled August 15, at the rate of about 11 kg. per hectare in rows 30 cm. apart.

Canadian, one of the earliest varieties, ranked first in yield, with 26,600 kg. of seed per hectare. Dutch rape, which yielded the largest quantity of straw, was one of the lowest in seed production. Canadian also led in fat content of the grain, with 43.91 per cent. The results likewise indicated that the rank-growing Holstein rape is best adapted to a good soil and a mild winter climate, while Dwarf rape can be grown on poor soils and under more unfavorable weather conditions.

A common error in germination tests (*Abs. in Centbl. Agr. Chem., 34 (1905), No. 4, pp. 253–255*).—The germination in a seed tester of 31 samples of seed of oats and wheat ranged from 49 to 99 per cent, but the results obtained with this seed under field conditions differed widely from these figures.

Of oats having shown a germination of 94 per cent only 54 per cent was viable in the field, and of another lot with a germination of 81 per cent in the tester only 13 per cent produced plants when sown in the open soil. Two lots of wheat having shown a germination of 63 and 62 per cent contained only 8 and 4 per cent, respectively, of viable seeds under field conditions. The average difference in germination in the tester and viability in the field was 34 per cent.

This seed was produced under abnormally low temperature conditions and had been injuriously affected by early fall frosts. Upon further investigation it was found that the embryos either lacked normal development or had sustained injuries. The embryos in many cases were bent and in some instances approached a spiral shape. An injured condition was also manifested by a brownish-colored tip or base.

The vitality of buried seeds, J. W. T. DUVEL (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 83, pp. 22, pls. 3, fig. 1*).—From December 19 to 23, 1902, 32 sets of 112 samples of seeds, each representing 109 species, 84 genera, and 34 families, were mixed with earth, placed in porous clay pots, and buried in heavy clay soil. Eight sets were buried 6 to 8 in. deep, 12 from 18 to 20 in., and 12 more from 36 to 42 in. deep. Of the larger kinds each sample contained 100 seeds, but for most samples 200 seeds were taken. Control samples were stored in cloth bags in a dry room.

A complete series of 3 sets was taken up in November, 1903, and subjected to germination tests in the greenhouse, together with complete sets of control samples tested in the greenhouse and in the germinating chamber. The tabulated results of the tests show that 24 species of the buried seeds had either decayed or germinated and afterwards decayed, and that the seeds of 73 species had not completely lost their vitality while buried. Results as to the remaining species were indefinite.

Corn, sweet corn, corn cockle, cabbage, cotton, peas, beans, buckwheat, wheat, and barley were all decayed when taken up. The seeds of cheat (*Bromus secalinus*) and upright cheat (*B. racemosus*) completely lost their vitality, and it is concluded that where cheat is found in grain fields or elsewhere it has come from seed recently sown.

In studying the relation of depth of burial to vitality the average germination of all samples was found to be as follows: Original tests, 63.2 per cent; control samples in germinating chamber, 57.5; control samples in greenhouse, 53.2; samples buried 6 to 8 in., 20.5; buried 18 to 22 in., 26.5; and buried 36 to 42 in., 31 per cent. The seeds of the Trifoliums and closely related genera, including Lespedeza and Medicago, deteriorated very greatly while in the soil.

The seeds of the common cultivated sunflower, common garden lettuce, and oats had lost their vitality, while those of the wild sunflower germinated 43.5, 64, and 66.5 per cent; those of prickly lettuce 63.5, 69, and 69.5; and of wild oats (*Avena fatua*), 9, 8, and 18 per cent, respectively, for the 3 different depths.

From these results it is pointed out that many weeds can be destroyed by deep plowing and leaving the soil undisturbed for some time; that the seeds of cultivated plants lose their vitality, while the seeds of weeds retain their power to grow remarkably well when buried; and that the vitality in all seeds is best preserved by careful harvesting and storing in a dry and comparatively cool place. The results further indicated that the deeper seeds are buried the better the vitality is preserved; that hard seeds of the same species retain their vitality much better than those with softer seed coats; and that unhulled seed, especially of the grasses, retains its power of growth better than hulled seed.

Destruction of wild mustard, J. B. MARTIN (*Prog. Agr. et Vit. [Ed. l'Est], 26 (1905), No. 21, pp. 634–636*).—Of different solutions used for the destruction of wild mustard, a 3 per cent solution of copper sulphate and a 20 per cent solution of iron sulphate were most effective, but the iron sulphate was injurious to the crop.

HORTICULTURE.

Tomatoes under glass. Methods of pruning tomatoes, G. E. STONE (*Massachusetts Sta. Bul. 105, pp. 3–28, 38, 39, figs. 5*).—A summary is given of the results secured at the different experiment stations in this country with tomatoes as regards soils and fertilizers, solid beds and benches *v.* pots, transplanting, pollination, time required to grow crop, yield per square foot, pruning, etc., with the details of experiments by the author on pruning tomatoes.

In one experiment, when a few of the lower leaves were removed from plants trained to a single stem, there was a gain of 32 per cent in stem growth and 18 per cent increase in the size of the fruits over unpruned plants. In 3 other experiments extending over 1, 2, and 3 months, respectively, with plants trained to 2 stems, the

removal of the lower half dozen or more leaves resulted in an increased gain in size of the fruit of 21, 10, and 6 per cent, respectively. These results indicate that the beneficial influence of pruning off the lower leaves gradually decreases with time. The results of experiments in training to different numbers of stems is summarized in the table below:

Yield and size of tomatoes by different systems of pruning.

System of pruning.	Number of plants.	Average weight of fruit.	Average weight of fruit per plant.	Average number of fruit per plant.
		Grams.	*Grams.*	
One stem	17	112	4,135	38
Two stems	50	96	4,874	50
Three stems	25	90	5,212	57
Four stems	8	85	5,027	58
Normal	19	84	4,383	53
Three stems, leaders cut	8	150	5,444	36

When the leaders were not cut back the smallest number of fruit per plant was obtained on the plants trained to a single stem. These fruits were of good size and the plants thus trained produced the earliest fruit of all the different methods of training. The yield also on equal amounts of trellis space was the greatest by this system of training.

"The greatest average weight of individual fruit, as well as the greatest weight per plant, however, was given by the 3-stem system where the leader was headed in, whereas in the average number of fruit per plant this system is lowest. There was only one experiment in which heading in was practiced. . . . In general, however, these experiments show that if we wish to obtain large fruit with a tolerably good number per plant the single leader constitutes one of the best systems, with the 2, 3, and 4-shoot systems following in tolerably uniform succession. No doubt the largest fruit and the greatest acceleration in maturity can be obtained by heading in the leader. . . .

"Undoubtedly the best system of growing greenhouse tomatoes is to plant 12 to 16 in. apart in the rows, prune to the 1-stem system, and head in or cut back the leaders above the fourth or sixth cluster of fruit, as circumstances require."

The principles of mushroom growing and mushroom spawn making, B. M. Duggar (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 85, pp. 60, pls. 7*).—The results are here given of a number of years' research work on the problems of mushroom culture and spawn production. The more popular results of the work, including efficient methods of spawn production, are reported in one of the farmers' bulletins of this Department (E. S. R., 16, p. 367).

In the present bulletin the more technical phases of the work are given, including the results of spore germination, studies of different nutrient solutions, tissue cultures of different species of mushrooms and media for their growth, temperature and moisture experiments, compost preparation, installing, spawning, and casing beds, comparisons of different kinds of spawn, experiments in mushroom culture, and tests of the vitality of mushroom spawn. Detailed directions are given for mushroom spawn making on a commercial scale. An account is also given of the cave facilities in the United States and a discussion of the open-air culture of mushrooms The principal species worked with was *Agaricus campestris.*

Further work by the author has confirmed the results of Miss Ferguson (E. S. R., 14, p. 121) relative to the value of small portions of mycelium of the mushroom fungus in stimulating spore germination. The tissue-culture method of spawn production has been satisfactory for at least 40 species of mushrooms grown. The addition of nutrient salts to sterilized media in tissue cultures was not found useful. Acid media does not give satisfactory results.

The best temperature at which to grow mushrooms is placed at 53 to 58° F. They grow more rapidly at a higher temperature, but such higher temperature also favors the development of foreign fungi, molds, and bacteria, as well as insects, and the quality of the mushroom does not appear to be as good as with the lower temperature. Freshly fermented manure gives the best results in mushroom culture and should include the straw used in bedding the animals. Cereal straw appears to be better than that from grasses. The manure from horses fed hay and green feed does not give satisfactory results.

Commercial fertilizers appear to add nothing to the value of good horse manure for mushrooms, though beds to which cotton-seed meal were added gave slightly increased yields. The experiments indicate that the temperature of the beds should be allowed to fall to about 70° F. before they are spawned. Exhausted beds should be discarded from the standpoint both of profit and sanitation.

Outdoor mushroom culture is seldom commercially profitable, since temperature and moisture conditions can not be controlled. It is thought that the most favorable regions for mushroom culture out-of-doors are in Eureka and San Francisco, Cal. The absolute moisture condition for mushroom beds and bricks in spawn making is placed at 40 per cent. The vitality of spawn appears to decrease rapidly with age. Brick spawn appears to maintain its vitality longer than the flake material.

A number of American firms are now manufacturing spawn in accordance with the methods described by the author. About 50,000 bricks were sold in 1904, and it is believed that this amount will be increased to several hundred thousand in 1905.

Pure culture mushroom spawn, F. CANNING (*Amer. Florist, 24 (1905), No. 891, p. 1029*).—The author states that he has used a number of pounds of the pure mushroom spawn developed by this Department.

A noticeable feature of the mushrooms produced from this spawn appears to be the evenness of size, weight, solidity, and tenderness. At the time of writing mushrooms averaging ¼ lb. in weight were being picked which had not lost their tenderness. The Columbia variety is considered especially satisfactory, as it looks well for market.

Edible and poisonous mushrooms, G. MCCARTHY (*Bul. N. C. Bd. Agr., 26 (1905), No. 1, Sup., pp. 3–24, figs. 4*).—A botanical classification and illustrations and descriptions are given of a large number of edible and poisonous mushrooms which grow in North Carolina.

The American fruit industry and the development of American fruit exports, P. J. SCHLÖSSER (*Die amerikanische Obstindustrie und die Entwickelung des amerikanischen Obstexportes. Frankfort: Trowitzsch & Son, 1905, pp. 72, dgm. 1*).—The author visited America and describes the fruit industry in different sections of the country with reference to cultural practices and the utilization of the different fruits. Statistics are given showing the exports of fresh, canned, and evaporated fruits from the United States to different countries of the world.

General considerations in regard to pruning, G. E. STONE (*Massachusetts Sta. Bul. 105, pp. 33–39, figs. 3*).—A discussion of some of the general principles of pruning plants.

Winter injury to fruit trees, H. J. EUSTACE (*New York State Sta. Bul. 269, pp. 323–343, pl. 1*).—An account is given of the injuries to fruit trees in different sections of New York during the winter of 1903–4, which was unusually long and cold, and of different methods of treating injured trees.

The minimum temperature of the winter ranged from −10° to −15° F. in the fruit-growing sections of western New York and −40° F. in the Hudson River Valley. The season of 1903 had been especially trying on the trees, owing to early and prolonged drought, excessive fall rains, and serious ravages by insect pests. These factors combined with the long cold winter caused the unusual injury. All kinds of fruits were more or less injured, the peach and pear suffering most. The branches and trunks were most commonly injured, the roots seldom.

The external appearance of injured trees at the end of the winter was normal, but upon cutting into the trunk anywhere above snow line the bark and wood showed marked discoloration which decreased in intensity from the snow line up. It was found impossible to tell by the appearance of the wood and bark in the spring whether a tree was dead or not, since some trees in which both wood and bark were discolored black and which all believed were dead recovered from the injury and made a good growth during the succeeding two years. The intensity of the discoloration, however, is an index of the degree of injury.

Peach trees, 1 to 6 years old, were much less injured and recovered much more rapidly than older trees. Badly discolored pear trees, 2 to 5 years old, usually recovered. Generally speaking, older trees were much more seriously injured than young trees. Orchards located on low sites and in hollows or pockets were injured most and the wind damaged many orchards on exposed western slopes. A list is given of varieties of apples, peaches, pears, cherries, blackberries, quinces, and grapes that were most injured.

In experiments to determine the best method of pruning injured trees some young trees were cut back below the snow line. Older trees were sometimes cut back to the large limbs or "dehorned," sometimes moderately pruned, or left unpruned. Peach or pear trees, 7 or 8 years old or more, when pruned back to the main branches, were killed, while the young trees thus treated generally recovered and made a satisfactory growth. Both old and young trees moderately pruned back usually made a good recovery and were often thus saved when trees not pruned back at all died. Many of the trees not treated at all, however, recovered from the winter injury and made a fair crop of fruit in 1905. Trees that did not bear a crop of fruit in 1904 made a much better recovery than those that carried even a light crop. Moderate pruning on the whole gave much more favorable results than no pruning.

The apples of New York, I, S. A. BEACH, N. O. BOOTH, and O. M. TAYLOR (*New York State Sta. Rpt. 1903, pt. 2, pp. XX+409, pls. 129, figs. 10*).—A comprehensive account of the apples grown in New York, including notes on the botanical classification of apples, the origin and development of apple culture in New York, the adaptation of varieties to particular regions, and a discussion of what a variety is, with technical descriptions of all of the varieties of winter apples grown in New York and an account of their commercial importance.

The apples described include varieties which are in season with Tompkins King and Hubbardston and all those which ripen later. Under each variety described references to the literature on the variety are first given, its synonyms are then noted, followed by an historical account, and then a description of the tree, fruit, season of ripening, uses, etc.

On account of its completeness this report should prove of unusual value to orchardists. It is attractively and substantially bound and the numerous half-tone and colored plates serve a distinctly useful purpose in the determination of varieties.

Fifth report of the Woburn Experimental Fruit Farm, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt., 5 (1905), pp. 121, pls. 2*).—This report deals with the results of experiments with apple trees. The work was begun in 1894 and has been carried on continuously since.

The general plan of the experiments and results secured up to 1900 have been previously noted (E. S. R., 12, p. 749). The injurious effects of grass on apple trees and the probable cause of the same has since been reported upon (E. S. R., 15, p. 474), as has also the results of fertilizer experiments (E. S. R., 16, p. 875). Most of the work has been carried on with dwarf trees, though standards have been used in many instances.

The size of the leaf and fruit of apple trees has been found to decrease quite uniformly with the age of the tree up to ten years. The size of the fruit does not appear to be influenced by the size of the crop so long as the crop is not so excessive

as to overload and weaken the tree. Thinning the crop below this limit is, therefore, of no advantage. Cutting back the trees at the time of planting out has resulted in more fruit than where the trees were not cut back until a year later Unpruned trees have borne crops three times the value of those pruned severely and 50 per cent greater than those pruned moderately. It is thought that with precocious trees these results might not hold.

Summer pruning, shaping, and pinching have not produced useful results. No difference in results has been observable whether trees were pruned in the early fall, midwinter, or spring, or whether they were pruned during or just before hard frosts.

Root pruning trees every year practically stopped all growth. Less frequent root pruning resulted in proportionately less injury. Recovery began the second year after root pruning was done and was accompanied by relatively heavy fruiting. Two-year-old bush apple trees proved better for transplanting than 1, 3, or 4 year old trees. Two-year-old standard trees also proved better than 4-year-old trees.

The effect of grass 5.5 and 6 ft. away from apple trees produced marked results. The crops on these plats were more than double the normal without any diminution in the size of the fruit. The fruit which normally was of a deep green, occasionally tinged with red, assumed a brilliant red color, and in storage kept much better. The variety Potts kept 3 months longer than usual, and Bramleys were still good in June at the time of writing.

The serious injury of grass on the growth of apple trees, when it occupies the whole area under the trees, was brought out in former reports (E. S. R., 12, p. 749; 15, p. 474). The present experiment is believed to illustrate how a kind of treatment that is very injurious when carried to excess may be very beneficial when adopted in moderation. The amount of tree roots which entered the grass area was determined in 3 instances and amounted to but 0.9 to 2.4 ounces per tree. "Yet they must have conveyed something to the trees which has been sufficient to modify the whole character of the crop. This points strongly to the view that the action of the grass is due to some active poison."

Notwithstanding increased crops, higher colored fruit, and improved keeping quality, growers are cautioned against attempting to improve their fruits by partially grassing over their orchards, since the line between beneficial and injurious effects of grass is very narrow and requires further study. No difference has been noticed in the action of different grasses on the fruit. Grassing over pears, cherries, and plums has led to the same injurious effects as with apples. The application of iron sulphate or manganese sulphate at the rate of 27 lbs. per acre has had no noticeable influence on the color of apples.

Careless planting of trees, such as hacking off the roots with the spade, huddling them into too small holes when planting, pointing the roots downward, filling in the holes and packing down the dirt without any attempt at working it in around the roots, resulted in impairing the vigor of the trees during the first year or two, after which the trees recovered and at the end of 3 or 4 years had made a much better growth on an average than trees planted carefully according to accepted methods.

The reason for this better growth is thought to be explained by some other experiments in which trees were planted 2 ft. deep or more. The roots of the trees thus treated made no growth, but a new system was established from dormant buds at the usual depth, after which these trees made unusually good gains, overtaking trees planted normally. The point is made that this entirely new root system which had never been disturbed by transplanting served the trees better than the old system, and it is held that careless transplanting, combining the methods noted above, would likely lead to the establishment of a new root system.

Shortening the roots one-third of their length at the time of transplanting impaired the vigor of the growth of the trees but little, but removing two-thirds seriously

dwarfed the trees. Trees set 3 ft. deep in the ground and the soil put back in either reversed or regular order resulted in the dying of the old root system and the development of an entirely new root system at the usual depth of 6 to 12 in.

The older the trees were at the time of transplanting, the longer was the time required to develop the new root system. Trenching or subsoiling the hard clay subsoil of the experimental plats was without benefit to apples. Planting trees 4 in. too high or too low has not made any difference in the results obtained, the trees having readily adjusted themselves to their normal level. Trees appear to sink into the ground as they grow.

Mixing peat or compost in amounts equal to the bulk of soil removed in a square yard in planting has resulted in an increased growth due, it is thought, to the poor physical condition thus brought about. No such benefit has been obtained when chalk, flints, or gravel have been so used. Very early fall planting of trees was found advantageous, but there was no choice between plantings made in November and the following April.

The removal of apple blossoms was found very beneficial in the growth and future productiveness of early-bearing trees. Trees thus treated appeared to bear heavier crops for several years afterwards and not only the year when they were first allowed to bear. With varieties that come into bearing later it was not of so much advantage. During the early life of apples the trees may bear well or badly for several years in succession, but as they grow older there is a strong tendency toward bearing only in alternate years.

Extensive tables are given showing the measurements, etc., of the trees reported upon in the different experiments mentioned above. In the text the experiments themselves are explained and discussed at length.

The ripening of peaches, W. D. Bigelow and H. C. Gore (*Jour. Amer. Chem. Soc., 27 (1905), No. 8, pp. 915–922*).—A study was made of the composition of peaches at various stages of growth. The work of analysis began immediately after the June drop. The fruit was examined again when the stone began to harden and could be cut through with a knife only with difficulty, when market ripe, and when fully ripe. The varieties Triumph, Rivers, Early Crawford, Stump, Elberta, Orange Smock, and Heath Cling were employed. The results of the analyses at the different periods of development are given in tables. The season was abnormal, being very humid up to August 10 and very dry after August 20.

The data secured show that the peach contains practically no starch at any stage of growth. Between the time of the June drop and the market ripeness of the peach the weight increased on an average from 9.51 to 73.59 gm., the solids in the flesh from 0.9 to 9.72 gm., and the percentage of flesh from 64.55 to 92.49, while the weight of the stone decreased from 32.5 to 6.86 per cent of the weight of the whole peach. The proportion of solids to water in the flesh remains fairly constant throughout the whole period of growth. The stone, on the other hand, becomes harder and the percentage of water decreases.

The flesh of the peach increases in weight about eleven times between the June drop and market ripeness. The weight of reducing sugars increases nearly eight times, and sucrose and acids increase considerably more than this. The various forms of nitrogenous substances all increase in weight from the beginning to the end of the period of observation. Only 3 varieties of peaches were analyzed when fully ripe. Between market ripeness and full ripeness considerable growth takes place, there being an increase in both water and solid content and in reducing sugar and sucrose.

Studies on peaches, W. D. Bigelow and H. C. Gore (*U. S. Dept. Agr., Bur. Chem. Bul. 97, pp. 32*).—Part 1 of this bulletin is made up of compiled analyses of peaches; part 2 deals with the changes in chemical composition of the peach during growth

and ripening, and part 3 with the effect of storage on the composition of peaches. Part 2, dealing with the changes in peaches during growth and ripening, is noted above from another source.

In studying the effects of storage on the composition of market ripe peaches, one lot of fruit was kept at ordinary room temperature (77 to 86° F.), another in cold storage (32° F.), and a third lot in a common refrigerator (54 to 59° F.). By each method of storage the fruit lost weight, due not only to evaporation, but to actual decrease in the solids of the flesh. By storing at ordinary summer temperature marked changes occurred within 2 or 3 days.

The life of the peach can be prolonged only by reducing the temperature quickly after picking. Peaches stored at 32° F. changed much more slowly in composition. At the end of 3 or 4 weeks, however, the flesh may begin to discolor and there is a loss of flavor. The changes in the composition of peaches stored in a common refrigerator were intermediate between those stored at summer temperature and those in cold storage.

Besides the above experiments other data are given for the storage of very green peaches and of peaches taken when the stone was hardening These were placed in a common refrigerator at a temperature of 53.6 to 59° F. The results of these experiments on the whole were quite similar to those obtained when more mature peaches were stored in the ice box. "The rate of ripening of the green peach is not markedly more rapid than that of the more mature fruit."

Plums for home and market, W. J. GREEN and F. H. BALLOU (*Ohio Sta. Bul. 162, pp. 229–258, figs. 19*).—Directions are given for the planting and care of plums and descriptions of the sorts of European, Japanese, native, and hybrids that succeed best in the vicinity of the station.

The varieties described in each of these classes are arranged according to the season of ripening, beginning with the earliest, and the dates of blooming and period of ripening are noted in each case for the season of 1904. Many of the varieties mentioned are illustrated. In conclusion, a table is given showing in condensed form the classification and description of 107 varieties of plums grown at the station, with other data as to period of bloom, size and form of fruit, color, quality, etc.

Hybrids in their relation to grafting and wine, L. DANIEL (*Rev. Vit., 24 (1905), No. 606, pp. 89–96*).—The conclusions of the author are to the effect that there is a variation in vines which results from grafting, but this variation may be either useful or harmful.

The best varieties of French grapes can not be improved in quality by grafting, but may be rendered more resistant by this method. Hybrid grapes may be improved both in quality and resistance to Phylloxera by grafting. Variations produced by grafting appear frequently to be hereditary in vines. On this account the author advises the establishment by the government in the experimental fields now existing plats for the preservation of all the old French varieties as a means of comparison with future varieties and variations.

Analyses of American grape shoots, J. GÁSPÁR (*Ann. Inst. Cent. Ampélol. Roy. Hongrois, 3 (1905), No. 2, pp. 57–166, dgms. 9*).—Tables containing analyses of a large number of shoots of the varieties Portalis, Monticola, and Metallica of *Vitis riparia* and *V. solonis* are given with comments. The analyses show the size of the cuttings, water, dry matter, ether extract, and ash content.

The passion fruit, W. J. ALLEN (*Agr. Gaz. N. S. Wales, 16 (1905), No. 6, pp. 602–606, pl. 1, figs. 3*).—An account of the culture of this fruit in New South Wales, with a colored plate of the leaves, flower, and fruit, and illustrations of different vineyards which have been planted to it.

Notes on the growth and culture of vanilla, J. COSTANTIN (*Jour. Agr. Trop., 5 (1905), No. 48, pp. 163, 164*).—Mention is made of the rôle which fungi play in the development of orchids, more especially of vanilla, as an explanation of the practice

of planters in Réunion of tearing the vanilla vine from its living support at the time of flowering. The symbiotic relationship of vanilla and fungi has been previously noted (E. S. R., 16, p. 851).

In the author's investigations the period of flowering was considerably retarded in the presence of the fungus. By tearing the vine from its living support, therefore, the injurious effect of the fungus is minimized and this practice is given a rational explanation.

Vanilla culture in the Hawaiian Islands, A. INKERSLEY (*World To-Day, 9 (1905), No. 3, pp. 1012, 1013*).—An account of planting about 8,000 cuttings of vanilla in the region of Kona, Hawaii, where it is believed the climate is especially suitable for this crop.

A revised classification of roses, 1905, J. G. BAKER (*Jour. Linn. Soc. [London], Bot., 37 (1905), No. 258, pp. 70-79*).—A revised analytical key is given to the various groups of roses.

Our native orchids, W. H. GIBSON and HELENA L. JELLIFFE (*New York: Doubleday, Page & Co., 1905, pp. XXXVI+158, pls. 58, figs. 17*).—Illustrated descriptions with key are given of the orchids native to the region from Kansas east to southern Virginia and north to Manitoba and Labrador.

Ether forcing without a greenhouse, FLORA L. MARBLE (*Gard. Mag. [N. Y.], 2 (1905), No. 2, pp. 64, 65, figs. 7*).—An account of the etherization of 2 azaleas, 2 lilacs, and 2 deutzias in an old-fashioned chest and their subsequent growth in the living room of the house.

By etherizing these shrubs 72 hours from November 4, blooms were secured at Christmas time, the average cost of etherizing being 15 cents per plant. One azalea, Simon Mardner, 1 lilac, Charles X, and 1 deutzia were given a double dose of etherization with half the quantity of ether first used. This proved especially beneficial with these varieties, since the 1 deutzia etherized for only 72 hours failed to start into growth until late in the season, not producing bloom until February.

Two examples of grafts, L. DANIEL (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 3, pp. 214, 215*).—Tall morning glory (*Ipomœa purpurea*) and *Quamoclit coccinea* were grafted by the author on the sweet potato (*Batatas edulis*).

The first 2 are annuals, while the sweet potato in that climate is perennial, developing very slowly and producing tubers only at the end of several years. On the other hand, the 2 plants mentioned first are well adapted to the climate. As a result of these grafts tubers the size of 1 cm. were formed at the end of the first year, the tubers formed when *Q. coccinea* was used as a scion being smaller than when tall morning glory was used. The control sweet potatoes which had not been grafted produced no tubers.

In another instance *Helianthus multiflorus*, which is perennial and in that climate reproduces itself exclusively by tubers, was grafted on *H. annuus*, a variety of sunflower which grows well there, producing fertile seeds in abundance. As a result of this graft the *H. multiflorus* scion produced a large number of flowers, one of which contained a fertile seed. From this seed was grown an *H. multiflorus* which had conserved the characters acquired by the scion.

FORESTRY.

Forest irrigation experiments, K. BÖHMERLE (*Centbl. Gesam. Forstw., 31 (1905), No. 4, pp. 145-172, figs. 8*).—An account of irrigation experiments carried out near Vienna, Austria, during the years 1901 to 1904.

The forest was 56 years old in the beginning of the experiment and consisted of Austrian pine. Tables are given showing in detail the diameter growth of each of the trees on the irrigated and unirrigated plats during each year of the experiment. The increment percentages on the unirrigated plat during each year was as follows: In

1901, 2.3 per cent; in 1902, 5.2; in 1903, 4.5, and in 1904, 3.2. On the irrigated plat the increment percentage in 1901 was 5 per cent; in 1902, 7.4; in 1903, 7.1, and in 1904, 5.5.

These figures show an increased increment of about 10 per cent in favor of irrigation. The favorable effect of irrigation was noticed the first year, especially with the lower class trees.

Forest irrigation experiments, A. Cieslar (*Centbl. Gesam. Forstw., 31 (1905), No. 5, pp. 195–211, figs. 2*).—An account of irrigation experiments with young stands of white and Austrian pine and spruce during the period 1901 to 1904, inclusive.

From May to September of each year from 38 to 44 irrigations were given. The dates of each irrigation; the character of the year as regards precipitation, etc.; the number of trees which lived on the different plats, and the growth they made are all shown in detail. Irrigation proved especially efficient in the case of spruce. White pine seemed to be injured by irrigation except in the one very dry season of 1904, when marked results in favor of irrigation were noted. Austrian pine appeared not to be injured by irrigation in 1903, and was greatly benefited in 1904.

In other observations the author notes that Austrian pine withstands drought much better than white pine, and in dry situations should be selected for planting in preference to white pine.

The dead cover of forests and nitrogen, Hornberger (*Ann. Sci. Agron., 2. ser., 10 (1905), I, No. 2, pp. 220–230*).—The author briefly reviews the work of E. Henry (E. S. R., 16, p. 444) relative to the decomposition of dead leaves in forests and the fixation of atmospheric nitrogen, and gives the results of his own experiments conducted along the same lines.

The zinc boxes used in the author's experiments were 20 cm. square and 10 cm. deep. Holes were punched in the bottom so that water could escape and the bottom was covered with filter paper. Six of the boxes used contained a small amount of sandstone in the bottom. The leaves used in the experiment were those of oak, beech, pitch pine, ash, hornbeam, and acacia.

They were gathered in the fall and placed on screens and covered over with paper to keep the dust from them until they were needed in the experiment. Part of the leaves were then analyzed and the remainder put in their respective boxes and left in the open from February 6, 1903, to February 6, 1904, exposed part of the time to the rain and all of the time to the air. At the end of the year the leaves in all of the boxes were again analyzed with reference to their nitrogen content.

In all except 2 cases the total nitrogen content of the leaves had decreased instead of increasing, as was the case in Henry's experiments. Even in the 2 cases in which there was an increase the increase was so slight as to be within the limits of analytical error.

Observations on the preceding memoir, E. Henry (*Ann. Sci. Agron., 2. ser., 10 (1905), I, No. 2, pp. 231–236*).—The author reviews the above article by Dr. Hornberger on the decrease in nitrogen content of decayed forest leaves, and argues that the results of the experiments under the conditions in which they were conducted were not other than what might have been expected.

In gathering the leaves and allowing them to dry before the experiment began, the germinative ability of the micro-organisms originally existing on the leaves in the forest would be largely lost, and the material would therefore become nearly sterile and not able to function as normal dead leaves in the forest. In order to secure results of value it would be necessary to carry on the experiment under conditions exactly as they exist in large forests.

The recent work of a number of other investigators is cited to show that nitrogen-fixing bacteria really assimilate the free nitrogen of the air in the decomposition of forest leaves.

All the spruces worth cultivating, J. F. JOHNSTON (*Gard. Mag.* [*N. Y.*], *2* (*1905*), *No. 1, pp. 24–26, figs. 8*).—This is the second article in a series of monographs for the use of expert gardeners, designed to bring our knowledge of the subject up to date. It describes the various species of spruces, distinguishing their uses from a horticultural standpoint. A key to distinguish the spruces is included and illustrations given of a number of the more important species.

Productivity of Siberian larch, GUSE (*Centbl. Gesam. Forstw., 31* (*1905*), *No. 6, pp. 251, 252*).—Data on the height and diameter of trees in a Siberian larch forest established by Peter the Great in Finland. The trees vary in age from 80 to 164 years.

Mallet eucalypt bark better than black wattle, D. E. HUTCHINS (*Agr. Jour. Cape Good Hope, 26* (*1905*), *No. 6, pp. 784–789*).—Mallet bark is stated to be the produce of one of the West Australian gums, known botanically as *Eucalyptus occidentalis.*

In a comparison between mallet bark and black wattle, mallet bark contained 39.35 per cent of tannin matter, while black wattle contained but 35.96 per cent. The mallet eucalypt appears to be at home in the southwest of Cape Colony. A table is given showing the growth of 37 trees 2½ years from seed. The height varies from 2 to 11 ft. and the average is 6 ft. 6 in. The soil on which these mallet eucalypts are growing is declared to be too poor for most agricultural purposes.

Analysis of mallet bark (*Natal Agr. Jour. and Min. Rec., 8* (*1905*), *No. 6, pp. 578–580*).—Analyses with reference to the extract matter, tannin, nontannin, and moisture, are given for salmon gum (*Eucalyptus salmoniphloia*), gimlet (*E. salubris*), white gum (*E. redunca*), and mallet (*E. occidentalis*). The mallet appears to contain much the larger amount of tannin. The tannin of the salmon gum, however, is relatively more astringent than in the other barks tested.

Hedgerow timber, A. C. FORBES (*Jour. Bd. Agr.* [*London*], *12* (*1905*), *No. 3, pp. 129–136*).—This article considers hedgerow timber from the standpoints of ornamental gardening, wind-breaks, and as a natural source of wealth in rural districts, and contains suggestions on the planting, pruning, and management of hedgerow timbers.

Forest planting and farm management, G. L. CLOTHIER (*U. S. Dept. Agr., Farmers' Bul. 228, pp. 21, figs. 3*).—Reprinted with minor changes from the Yearbook of the Department of Agriculture for 1904 (E. S. R., 17, p. 147).

New source of rubber (*Mo. Consular and Trade Rpts.* [*U. S.*] *1905, No. 298, pp. 136–138*).—United States Consul Aymé reports that the India rubber exported from Para has been traced to 4 main sources: "India rubber proper from the *Hevea brasiliensis*, 'caucho' from the *Castilloa elastica* or a closely allied species—*Castilloa ulei*, 'maniçoba' from the *Manihot glaziovii*, and 'mangabeira' from the *Hancornia speciosa.*"

It appears that much of the rubber known as "fine Para," and which was supposed to be the exclusive product of *H. brasiliensis*, is really obtained from a tree identified as *Sapium aucuparium*. This tree has many native names, such as tapurú, murupita, curupita, etc. A prominent characteristic of the Sapium is its polymorphism. The same tree assumes widely different aspects under varying circumstances, such as sun, shade, dry ground, and wet or periodically inundated ground. The rubber from the tapurú tree it is claimed can not be distinguished from pure hevea rubber.

A rubber obtained from the upper Xingú River and which is known as "borracha fraca" or "weak rubber" closely resembles specimens of the murupita or tapurú rubber, and is believed by the author to be tapurú rubber. The Sapium appears to be a hardy tree and grows with great rapidity. A 5-year-old tree in the botanic gardens measured 8 in. in diameter 3 ft. from the ground. It is believed certain that the latex of this tree can be successfully mixed with hevea latex and be therefore of great commercial importance.

Rubber planting industry in Ceylon (*Jour. Soc. Arts, 53* (*1905*), *No. 2751, pp. 969, 970*).—There are at present about 25,000 acres under rubber cultivation in Ceylon,

the acreage having increased nearly 44 per cent during the past year. In the Malay Peninsula the extent of the rubber planting is placed at 30,000 acres, in Java at 5,000 acres, and in India and Burma at 5,000 acres.

Rubber in Hawaii, J. G. SMITH (*Hawaii Sta. Press Bul. 13, pp. 11*).—A brief account of American, African, and Asiatic rubber plants, with suggestions as to rubber culture in Hawaii.

The most suitable species for culture in Hawaii appear to be *Manihot glaziovii* and *Ficus elastica*. The first of these, it is stated, should comprise the larger proportion of all new plantations because of its very rapid growth and early maturity. *F. elastica* grows more slowly but yields much more abundantly when it finally reaches bearing age. Other promising sorts for Hawaii are maniçoba rubber (*Hancornia speciosa*) and the white rubbers (*Sapium tolimense*, *S. verum*, and *S. stylare*).

It is believed that conditions in Hawaii are very favorable for the cultivation of the Ceara trees. One company has already planted 100,000 seeds of this species and expect to have half a million trees growing within 2 years.

Results of tapping experiments in a Kickxia plantation, O. WARBURG (*Tropenpflanzer, 9 (1905), No. 7, pp. 385–390*).—An account of the tapping of Kickxia trees 5½ years old to determine the character of caoutchouc produced and the profitableness of working trees of that age.

The results obtained indicate that caoutchouc from trees of this age while not of the best has considerable commercial value. It is not believed advisable to systematically work trees of this age. In certain cases, however, tapping may be profitable. Thus one man can secure from 5 trees this age about 400 gm. of dry rubber per day having a market value of at least 38 cts., while the cost of production is about 18 cts. The experiment was preliminary to a more thorough investigation which is to be undertaken.

Estimate of cultivated rubber in the world (*India Rubber Jour., n. ser., 30 (1905), No. 5, pp. 259, 260*).—An account of the planting of rubber in Ceylon with an estimate of the acreage of cultivated rubber in the different countries of the world in 1905. The total acreage is placed at 149,950.

DISEASES OF PLANTS.

Notes on parasitic diseases of plants, F. BŒUF (*Bul. Dir. Agr. et Com. [Tunis], 9 (1905), No. 35, pp. 245–269, figs. 16*).—A number of fungus diseases of cereals, fruit trees, vegetables, and ornamental plants are described, and where remedies are known suggestions are given for their use.

Attention is called particularly to the parasitic growth of a number of species of broom rape upon various vegetables, forage plants, etc. There are said to be 13 species of Phelypæa and 20 of Orobanche in Tunis that are known to be parasitic on various plants, the most of them occurring on vegetables. Constant care that the seed of broom rapes should not be included in seed of economic plants is urged.

Diseases of plants in the Tropics, G. DELACROIX (*Agr. Prat. Pays Chauds, 5 (1905), Nos. 29, pp. 164–173; 30, pp. 230–245*).—In continuation of previous papers (E. S. R., 16, pp. 676, 1091), the author gives a classification of parasites, describes the different forms of parasitism, and discusses the various causes of parasitic attack.

The invasion of the host plant by fungi is due to positive chemiotactic action, and facultative parasitism is also to be explained in this way. Immunity and predisposition to disease are determined by the chemical composition of the host. Slight modifications seem able to secure some degree of immunity. The effect of age of plants, soil, atmospheric conditions, etc., on disease is discussed.

A blight of barley and oats (*Jour. Bd. Agr. [London], 12 (1905), No. 6, pp. 347–350, figs. 2*).—A description is given of a blight of barley and oats caused by *Helminthosporium gramineum*.

The fungus produces upon the leaves and leaf sheaths minute, scattered, pale-green spots, which increase in number and size, and the leaf gradually changes to a sickly yellowish-green color, after which it ceases to grow. The plants attacked are checked in their development, and in bad cases the crop dries up without producing more than a small percentage of well-developed heads.

In addition to the hosts mentioned the fungus has been observed on wild barley, and it probably occurs on a number of wild grasses, from which it may pass to cultivated oats and barley. It is thought probable that the fungus may be conveyed by seed, and treatment with fungicides or hot water is recommended.

A preliminary note on clover diseases in Tennessee, S. M. BAIN and S. H. ESSARY (*Science, n. ser., 22 (1905), No. 564, p. 503*).—A preliminary report is given of investigations carried on at the Tennessee Station to ascertain the cause of several diseases of clover. In the vicinity of Knoxville this crop begins to die in the summer following late winter sowing, and the trouble has been popularly attributed to some condition of the soil. The authors' investigations have shown that the malady is independent of soil conditions, but is principally due to a specific fungus.

Early in the season the clover rust (*Uromyces trifolii*) and *Pseudopeziza trifolii* were both noticed upon clover, but were of comparatively little importance. A more destructive disease is that caused by *Macrosporium sarcinæforme*. This fungus attacks alsike clover as well as the red, and appears capable of destroying the plants without assistance from any other parasite. The most destructive disease thus far observed is due to an undescribed species of Colletotrichum. In general appearance this disease is said to resemble the anthracnose of clover, which has been attributed to *Glœosporium caulivorum* (E. S. R., 14, pp. 159, 773).

The Colletotrichum referred to causes considerable injury to young clover plants in early summer, where it confines its attacks to the petioles of the leaves. The greatest damage, however, is said to be to the blooming and fruiting plants, which are attacked most frequently just below the flowerheads, but sometimes at other points causing the blackening and death of a limited region, eventually destroying the entire plant.

The details of the investigations are to be published in a bulletin of the Tennessee Station.

Diseases of tobacco, M. T. COOK and W. T. HORNE (*Estac. Cent. Agron. Cuba Bul. 1, pp. 17-22, figs. 4*).—Descriptions are given of a disease of tobacco in the seed bed due to *Rhizoctonia* sp., the mosaic disease, the leaf spot caused by *Cercospora nicotianæ*, some curing house troubles, and the occurrence of a broom rape (*Orobanche ramosa*) in tobacco fields. Fungus diseases so far have not seriously threatened the crop in Cuba, but the author thinks best to describe those enumerated above, and suggests methods for their prevention.

The duration of Gymnosporangium and its relation to rusts, E. PRILLIEUX (*Bul. Soc. Nat. Agr. France, 65 (1905), No. 6, pp. 464-479*).—In investigating some of the heterœcious rusts the author has studied the phenomena relating to the Gymnosporangium on junipers and its Rœstelia stage or rust on pears and ornamental hawthorns.

All trees and shrubs carrying the so-called cedar apples should be cut out when in the vicinity of pears, apples, hawthorns, and similar plants. The Gymnosporangium is perennial in the tissues of various species of juniper, and it is known to persist for 4 to 8 years in the common juniper and 12 or more years in *Juniperus sabina*. The presence of either of these species of shrubs makes combating the rust on the pear and other economic plants all the more difficult.

The black spot, or scab, of the apple and pear, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 27 (1905), No. 2, pp. 169-174*).—Notes are given on the occurrence of the black spot, or scab, due to *Fusicladium dendriticum* and *F. pyrinum*. The distribution and amount of injury caused by these fungi throughout Australia is shown,

after which the author discusses the propagation of the fungi, methods by which they spread, etc.

Both apples and pears seem quite subject to attacks of these fungi in South Africa, and attention is called to the fact that while the regulations prohibit the introduction of apple trees for orchard planting there is no restriction against the introduction of seedlings for budding and grafting purposes, and it is thought that through these the disease is propagated and spread. Among the remedies suggested for the prevention of losses the author recommends the thorough application of Bordeaux mixture.

Fire blight, L. F. HENDERSON (*Wis. Hort. Soc. Bul. 5, pp. 8*).—This bulletin, which is a reprint of a press bulletin of the Idaho Experiment Station, gives a brief history and description of fire blight, together with approved remedies.

Black and gray rot in Indre, H. BLIN (*Rev. Vit., 24 (1905), No. 611, pp. 241, 242*).—During 1905 the black rot was especially destructive in the vineyards of Indre, the Lyonnais and Durif varieties being most attacked.

A commission composed of members of the viticultural society in cooperation with the departmental professor of agriculture have made a study of the situation, and for future treatments they recommend a winter treatment of iron sulphate 25 to 30 kg., sulphuric acid 1 liter, and water 100 liters. This is to be followed during the growing season by applications of a spray composed of water 100 liters, crystallized copper acetate 1 kg., and acetic acid 0.5 kg. The applications should be made with reference to the time of appearance of the rot.

For the prevention of the gray rot caused by *Botrytis cinerea* the application of a powder recommended by Zacharewicz is advised. This consists of plaster 60 kg. and sulphosteatite, containing 20 per cent copper sulphate, 40 kg., to be dusted over the vines at frequent intervals.

Treatment for Botrytis of grapes, L. DEGRULLY (*Prog. Agr. et Vit. (Ed. l'Est), 26 (1905), No. 19, pp. 561–566*).—Attention is called to the use of various mechanical treatments for preventing the attacks of *Botrytis cinerea* on grapes. These consist in the main of dusting the foliage with mixtures containing sulphur, lime, steatite, etc., often accompanied with Bordeaux mixture.

The author briefly describes experiments with fertilizers in which different rows of vines were treated with muriate of potash, calcium superphosphate, and nitrate of soda. The superphosphate appeared without effect as far as the disease was concerned, but the muriate of potash seemed to reduce the amount of disease, while those vines receiving the nitrate of soda were much more affected than any of those receiving treatment. As a supplemental treatment to the use of fungicides the author recommends attention to the fertilizers used. Where the disease is prevalent the amount of nitrogen should be diminished and potash increased.

It is claimed that the Botrytis is more severe after attacks of *Tortrix ambiguella* and the destruction of this insect is advised.

The rougeot of grape, L. RAVAZ and L. ROOS (*Prog. Agr. et Vit. (Ed. l'Est), 26 (1905), Nos. 39, pp. 363–370; 40, pp. 392–398, pl. 1*).—This disease, which has long been known, makes its appearance in the summer whenever the heat becomes extreme.

The leaves become altered and lose their rigidity, and the parenchyma becomes reddened, while the principal veins remain green. Later the leaves become brown and dead, the grapes are wilted, and the young shoots yellow. The diseased vines do not die suddenly, but their productivity is considerably diminished. A microscopic study of the tissues does not show any exceptional characters beyond the increased quantity of the red coloring matter, anthocyanin, and a greater abundance of starches and sugars. Later in the season the young growth does not show this unusual coloring, and the old leaves still remaining resume their normal coloration.

Numerous causes have been assigned to this disease, but the evidence seems to show that it is due to impaired nutrition and that it may be artificially induced in a number of ways. It is believed that an insufficiency of lime is at the base of the trouble. Experiments with lime and other fertilizers show that the disease can be controlled, the best results being obtained where potash salts were used in conjunction with lime, the potash seeming to make the lime more readily available to the plant.

Acariosis, brunissure, and erinosis, H. Faes (*Prog. Agr. et Vit.* (*Ed. l'Est*), *26* (*1905*), *No. 31*, *pp. 133–146*, *pl. 1*, *figs. 6*).—Acariose, or "court-noué," brunissure, and erinose of the grape are, according to the author, all caused by *Phytoptus vitis*, the different appearances assumed by the host plant being due to differences in varietal susceptibility, weather, etc.

For treatment the use of sulphur, lysol, mixtures of soap and an extract of quassia, and soap and tobacco gave good results, the latter proving the most efficient. The summer treatments should be preceded by thorough spraying of the vines in February or March with rather strong solutions of lysol, soap and carbolic acid, and soap, carbolic acid, and oil of rape seed. Winter treatment with strong solutions of copper sulphate or iron sulphate would probably be found effective.

A disease of cherry laurel, E. Raignault (*Jardin*, *19* (*1905*), *No. 437*, *p. 140*, *figs. 3*).—An account is given of attacks of *Coryneum beyerinckii* on the cherry laurel, and it is said to also infect the peach, cherry, almond, and apricot.

For the prevention of the disease the author recommends several sprayings during the growing season with Bordeaux mixture. On the cherry laurel the fungicide is less adherent on account of the smooth surface of the leaves. When occurring abundantly this blotch destroys the ornamental value of these shrubs by causing their defoliation.

Report of the botanist, J. Burtt-Davy (*Transvaal Dept. Agr. Ann. Rpt. 1904*, *pp. 261–320*, *pls. 22*, *maps 5*).—In a report of the botanist for the year ending June 30, 1904, notes are given on a number of plants of economic importance, together with a record of investigations on stock ranges, noxious weeds, plant diseases, and plants poisonous and injurious to stock.

Among the diseases discussed particular attention is devoted to the coffee leaf blight due to *Hemileia vastatrix*. This fungus has almost devastated the coffee plantations in the districts examined. Attention is called to the fact that an indigenous species, *H. woodii*, is quite common on two South African shrubs, *Vangueria infausta* and *V. latifolia*. These two species of fungi are so closely related that it is believed that the indigenous species could readily attack coffee plants if opportunity was offered.

Notes on the use of combined fungicides, L. Augrand (*Rev. Vit.*, *24* (*1905*), *No. 606*, *pp. 105–107*).—In seeking a combined fungicide for use against the powdery and downy mildew of grapes, the author carried on experiments with a number of mixtures, and the results obtained are briefly given.

Sulphur in a dry state is said to act too slowly, and to obtain a more rapid liberation of sulphurous acid a number of mixtures were tested. Calcium bisulphite and sodium hyposulphite were each added to Bordeaux mixture at the rate of 500 gm. per hectoliter. Both mixtures badly burned the foliage and considerable injury followed their use even when diluted to a considerable extent.

Later the author tried a mixture composed of Bordeaux mixture and an alkaline polysulphid with success. The formula and directions for making this mixture are as follows: Copper sulphate 4 kg. and water 100 liters, polysulphid 2 kg. and water 100 liters, and lime 2 kg. and water 25 liters. After a thorough solution, pour the lime water into the polysulphid solution, and this mixture in turn into the copper solution, stirring thoroughly. This mixture is said to be very effective in preventing both forms of mildew, is quite adhesive, and acts as a stimulant to the foliage, as judged from the dark green color of the plants.

A study of combined fungicides, J. DE BOUTTES (*Prog. Agr. et Vit. (Ed. l'Est), 26 (1905), No. 24, pp. 716, 717*).—A favorable report is made of the addition of sulphur to Bordeaux mixture, the combination being applied at one spraying.

Three years' use of this mixture in comparison with sulphur applied in the ordinary way has convinced the writer of its efficiency. The combined fungicide is said to be much more adherent than the ordinary forms, and its greater efficiency is attributed to the fact that the sulphur is deposited much more uniformly over the foliage than is possible when dusted in the form of powder. The acid in the copper sulphate mixture is said to materially add to the adhesiveness of the mixture.

The crystallization of soda fungicides, F. PORCHET (*Rev. Vit., 24 (1905), No. 616, pp. 377–380*).—The chief difficulty in the use of soda fungicides is said to be due to their rapid deterioration. When solutions of carbonate of soda and copper sulphate are mixed, a colloidal precipitate of a greenish-blue color is formed. Ordinarily after standing for a little time the precipitate loses its blue color, becomes crystalline, and is less adherent to the foliage than when freshly made.

The causes of the changes were studied, and the author says that if properly made the solution should stand for a long time without crystallization. Too great acidity favors crystallization and alkalinity retards it, though too much alkali makes the fungicide thick and less adherent. High temperatures favor crystallization. The use of impure chemicals and utensils that have been used for other fungicides also favors the depreciation of the fungicide. On this account a warning is given that all utensils, spray pumps, etc., should be thoroughly washed before using them for the preparation or application of fungicides containing soda compounds.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The mammals of Great Britain and Ireland, J. G. MILLAIS (*London, New York, and Bombay: Longmans, Green & Co., 1905, vol. 2, pp. 299, pls. 72*).—In this, the second of the three proposed volumes relating to the mammals of Great Britain and Ireland, the author continues a discussion of carnivora including the family Mustelidæ.

The greater part of the volume is devoted to a consideration of the habits and economic relations of various rodents, including squirrels, beaver, rats, mice, and voles. The anatomy and habits of each species of mammal mentioned in the volume are discussed in great detail, so that the work furnishes a fund of information of unusual value regarding these species. The illustrations accompanying the volume are of excellent quality.

Game laws for 1905, T. S. PALMER, H. OLDYS, and R. W. WILLIAMS, Jr. (*U. S. Dept. Agr., Farmers' Bul. 230, pp. 54, figs. 6*).—This bulletin is similar in purpose to those issued annually on the same subject since 1902. The information contained in the bulletin is more condensed than in the previous issues and recent changes in game laws are included.

The destruction of gophers, ground squirrels, and prairie dogs, A. MERAZ (*Com. Par. Agr. [Mexico], Circ. 20, pp. 11, pl. 1*).—These pests are described with particular reference to the damage which they cause to cultivated crops. In combating them various poisons have been tested, including phosphorus, strychnin, and cynanid of potash. Traps, fumigation with bisulphid of carbon, acetylene gas, and other remedies were also tried. Good results were obtained from the application of fumigation methods.

The destruction of rats, G. GANDARA and C. MACIAS (*Com. Par. Agr. [Mexico], Circ. 22, pp. 44, figs. 39*).—The distribution and injurious effects of rats are briefly discussed. Particular attention is given to a consideration of remedies for destroying these pests. Among the remedies discussed by the author mention may be made of baits containing phosphorus, arsenic, strychnin, and other solid poisons, as well as

the use of bisulphid of carbon and other gases, flooding, and destruction with infectious virus. The use of various traps is also considered. According to reports bearing on the use of virus this remedy is of considerable efficacy.

The destruction of field mice, H. SAGNIER (*Bul. Soc. Nat. Agr. France, 65 (1905), No. 5, pp. 378–386*).—In the district of Haute-Marne, field mice disappeared quite suddenly, apparently as a result of abundant rains and heavy snows during winter. The weather was extremely variable during the months of January and February. It appears, therefore, that the mice were frozen or drowned in the burrows.

The study of birds, C. J. PENNOCK (*Ann. Rpts. Bd. Agr. Del., 3–4 (1903–4), pp. 54–58*).—The feeding habits and economic relations of birds are briefly discussed, with notes on certain species of importance from an agricultural standpoint.

Two natural enemies of the farmer. The value of birds to the farmer, T. G. PEARSON (*Bul. N. C. Bd. Agr., 26 (1905), No. 8, pp. 41–44*).—Brief reference is made to the losses caused by noxious weeds and insects. Birds are discussed as friends of the farmer on account of their assistance in destroying weeds and injurious insects. Particular mention is made in this connection of the quail, meadow lark, robin, cuckoo, chickadee, chipping sparrow, night hawks, etc.

Birds from certain of the Philippine Islands, R. C. MCGREGOR (*[Philippine] Bur. Govt. Labs. [Pub.], 1905, No. 25, pp. 34, pls. 11*).—Lists are given of birds observed on the islands of Romblon, Sibuyan, Cresta de Gallo, Ticao, Cuyo, Culion, Calayan, Lubang, and Luzon. Certain species are described as new and notes are given on the distribution and feeding habits of some of the more important ones.

The horned larks and their relation to agriculture, W. L. MCATEE (*U. S. Dept. Agr., Bur. Biol. Survey Bul. 23, pp. 37, pls. 2, figs. 13*).—Horned larks occur at least at one season of the year in all parts of North America except the Aleutian Islands, southern Alaska, extreme southeastern part of the United States, and Central America. Over this whole territory one species prevails with 21 named varieties or subspecies.

The discussion presented in the bulletin is based on an examination of 1,154 stomachs of horned larks from 25 States and Territories. This examination showed the contents to consist of 20.6 per cent animal and 79.4 per cent vegetable matter. The amount of animal matter present in the stomachs increases greatly in April and May. In general the feeding habits of the horned lark of Europe appears to be very much like that of this country.

In former times the horned lark constituted a food product in the United States, and was killed in large numbers. These birds were also preyed upon by various hawks, owls, and shrikes. The feeding habits of all varieties of horned larks are almost the same except those of the larks which occur in California, the chief difference being in the vegetable food consumed. In California grain constitutes 40.2 per cent of the food of the horned larks, while in the country outside of California grain formed only 12.2 per cent of the diet. This is perhaps due to the scarcity of insects on the dry ranges.

Considerable difference of opinion prevails regarding the economic relations of horned larks, some of the farmers considering them pests, while others consider that the losses caused by them are not of great importance. Oats is the most important grain food of horned larks, and in California this cereal grows wild to such an extent that the presence of oats in the stomachs of horned larks can not be considered against them.

The author believes that in California, where horned larks depend chiefly upon grain for food, they may do considerable harm. Elsewhere they are believed to be of much value to the farmer. The nestling horned larks are highly insectivorous, but soon after leaving the nest they become much more vegetarian than even the adult birds.

An apparatus for collecting small arthropods quickly and in large numbers, A. Berlese (*Redia, 2 (1904), No. 1, pp. 85–89, figs. 2*).—The apparatus described in this article depends for its effectiveness upon the application of heat to the material in which small arthropods are concealed.

Moldy soil or other rubbish is placed in a receptacle in the top of the apparatus, the material lying upon a metallic screen with small apertures. Beneath the metallic screen which holds the material to be investigated is a funnel leading to a small tube containing alcohol or other preserving fluid. The funnel is surrounded by water which may be heated to a suitable temperature. The heat gradually dries out the soil or other material in which the insects are hidden, causing them to crawl downward in search of moisture and in so doing they fall into the metallic screen and ultimately into the funnel.

Index-catalogue of medical and veterinary zoology, C. W. Stiles and A. Hassall (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 39, pts. 12, pp. 839–902; 13, pp. 903–950*).—In these two parts of the index-catalogue the authors present an alphabetical list of authors for the letter K.

Insects injurious to grain and fodder crops, root crops, and vegetables, J. Fletcher (*Canada Cent. Expt. Farm Bul. 52, pp. 48, pls. 8*).—The author presents, for the use of farmers and gardeners, a general account of the common insect pests which attack cereals, forage plants, fruit crops, and garden vegetables.

The most effective insecticides are described and formulas suggested for preparing them. Among the insects injurious to grain and fodder crops mention may be made of Hessian fly, jointworm, wheat-stem maggot, wheat midge, western wheat-stem sawfly, grain aphis, wireworm, white grub, corn worm, grasshopper, pea moth, pea weevil, bean weevil, destructive pea aphis, clover-seed caterpillar, clover-seed mite, army worm, etc. The common pests of root crops and garden vegetables are also described and notes are given on means of combating them.

Insects of Herm and Jethou, W. A. Luff (*Guernsey Soc. Nat. Sci. Rpt. and Trans. 1904, pp 374–390*).—The insects observed in these islands are listed and notes are given on the habits of some of the more important species.

The insect galls of Indiana, M. T. Cook (*Separate from Ind. Dept. Geol. and Nat. Resources Ann. Rpt., 29 (1904), pp. 801–871, figs. 52*).—This contribution to the knowledge of insect galls is to be considered a part of the author's proposed monograph of the insect galls of North America. The present contribution includes a discussion of galls observed on plants in Indiana.

The cotton-boll weevil, P. Marchal (*Jour. Agr. Trop., 5 (1905), No. 50, pp. 229–234*).—A historical account is presented of the origin and distribution of this pest and the early literature relating to it. The habits and life history of the insect are discussed with particular reference to the conditions which are favorable to its distribution. Brief notes are also given on some of the conditions which are unfavorable to the pest, and upon its natural enemies.

The cotton caterpillar (*Jour. Jamaica Agr. Soc., 9 (1905), No. 9, pp. 312–317*).—Apparently the caterpillar, which has recently done most damage to cotton in Jamaica, is the common cotton caterpillar of this country. The insect is described in its various stages and notes are given on its habits and life history.

As a result of a number of spraying experiments with Paris green and arsenate of lead it is recommended that arsenical poisons be thoroughly applied to cotton plants as soon as the caterpillars appear. In moderately dry weather this application can best be made in the form of a dry mixture with lime or some similar substance. In wet weather arsenate of lead dissolved in water is recommended.

Methods of combating the cotton-boll weevil and the cotton caterpillar, A. L. Herrera (*Com. Par. Agr. [Mexico], Circ. 24, pp. 2*).—Brief notes on the approved remedies for the control of these two insects.

The early history of the Hessian fly in America, F. M. WEBSTER (*Proc. Soc. Prom. Agr. Sci., 26 (1905), pp. 110–117*).—A historical discussion of the origin of the Hessian fly is presented, together with notes on the early outbreaks of this pest and its distribution (E. S. R., 16, p. 622).

Locust destruction, W. H. BUSHBY (*Natal Agr. Jour. and Min. Rec., 8 (1905), No. 6, pp. 559–562*).—The use of an arsenical solution as a spray for the control of locusts has proved very efficient and also harmless to cattle which may graze upon the grass. During the past year 5 tons of arsenical poison was purchased for this purpose and has yielded satisfactory results. While it seems impossible to exterminate the pest by this method it furnishes a means of holding the locust within reasonable bounds.

The destruction of white grubs in the district of Meaux, J. BÉNARD (*Bul. Soc. Nat. Agr. France, 65 (1905), No. 5, pp. 375–378*).—For several years a bounty has been offered varying from 10 to 20 centimes per kilogram of white grubs. In a period of 6 years a total of 462,911 kg. were thus captured. Estimating 1,200 white grubs per kilogram this would mean the destruction of about 500,000,000 of the larvæ. In order to carry on this kind of warfare against insects, however, it is necessary to secure large quantities of money as well as devotion to the work.

The habits and metamorphosis of Lebia scapularis, F. SILVESTRI (*Redia, 2 (1904), No. 1, pp. 68–84, pls. 3*).—This predatory beetle appears to be quite influential in the destruction of the elm-leaf beetle. The habits of *Lebia scapularis* are described in considerable detail with especial reference to the behavior and metamorphosis of the larvæ in different stages. An elaborate description is also presented of the silk-producing apparatus of the larvæ.

Invasion of bark beetles in Vosges, RIVET (*Bul. Soc. Nat. Agr. France, 65 (1905), No. 3, pp. 198–207*).—During the year 1904 *Tomicus typographus* and *T. curvidens* were unusually numerous and attacked fir and other related trees. The habits of these two species are described in detail. The extent of infestation and the amount of damage caused by these insects are briefly indicated.

A note upon the "bee-hole" borer of teak in Burma, E. P. STEBBING (*Calcutta: Supt. Govt. Printing, India, 1905, pp. 19*).—A considerable percentage of teak in Burma is injured by the presence of insect burrows to such an extent that it is useless for shipbuilding purposes.

The author investigated such timber for the purpose of discovering the cause and remedy. It was found that the burrows were produced by a moth identified as *Duomitus ceramicus*. The chief natural enemies of this moth are woodpeckers. In controlling the pest it is recommended that observations be made to determine the trees in which the insect is present. All infested trees should then be cut in the cold season and utilized in such a manner as to destroy the insects in all stages.

Observations and studies on hazelnut disease and means of combating it, A. TROTTER (*Redia, 2 (1904), No. 1, pp. 37–67, figs. 7*).—As a result of a thorough study of hazelnut trees, it was found that the so-called hazelnut disease may be due to a variety of causes. In some cases it is the result of infection with parasitic fungi such as *Phyllactinia suffulta* and related species. In other cases the disease is produced by attacks of *Heterodera radicicola*.

Hazelnuts may also be badly affected by infestation with mites, particularly *Eriophyes avellanæ*, or by the attacks of leaf-eating lepidoptera, coleoptera, or finally by infestation with scale insects and other insect pests. A brief bibliography of the subject is appended to the article.

The vaporer moth, W. FORBES (*Jour. Bd. Agr. [London], 12 (1905), No. 7, pp. 420, 421, fig. 1*).—*Orgyia antiqua* attacks various fruit and garden trees, as well as ornamental shrubs. The insect is described in its various stages with notes on its life history. In combating this pest the webs should be collected and burned and infested foliage should be sprayed with Paris green at the rate of 1 lb. per 200 gal. of water, or with arsenate of lead.

The gypsy moth, A. E. STENE (*Nature Guard, 1905, Lesson 42, pp. 173-176, pl. 1*).—Attention is called to the great damage done to forest and other trees by the gypsy moth. The life history of this insect is briefly discussed and recommendations are made regarding means for controlling it.

Mites in rubber nurseries, S. ARDEN (*Agr. Bul. Straits and Fed. Malay States, 4 (1905), No. 6, pp. 229, 230*).—In a case of infested rubber trees the young leaves fall before they are fully developed, as when attacked by red spider.

The mite causing this trouble appears to be a species of Tarsonymus. The disease is chiefly confined to plants under unfavorable conditions and does not commonly affect trees after they are thoroughly established. In one instance rubber trees were badly affected while suffering as a result of an insufficient supply of water.

The red disease of the grapevine and its treatment, E. ZACHAREWICZ (*Rev. Vit., 24 (1905), No. 618, pp. 447, 448*).—The disease discussed by the author is due to the attack of *Tetranychus telarius*. The appearance of this mite is discussed and notes are given on its habits. In controlling the pest, good results have been obtained by the use of a mixture containing 95 parts powdered live lime and 3 parts pyrethrum powder.

Report of the secretary of the American Mosquito Extermination Society, H. C. WEEKS (*Bayside, L. I.: Author, 1905, pp. 5, pl. 1*).—A study was made of the mosquito problem at Wellfleet, Mass. It was found that a swampy worthless area of about 2,500 acres in the vicinity of the town was badly infested with mosquitoes.

In the treatment of this marsh it is recommended that a dike be constructed for the purpose of preventing the entrance of tide water. It is believed that this will enable a better quality of grass to grow on the salt marsh so that the area may be profitable for farming. This will lead to the introduction of proper drainage systems which in turn will prevent the development of mosquito larvæ.

Lantern traps for noxious micro-lepidoptera, A. L. HERRERA (*Com. Par. Agr. [Mexico], Circ. 25, pp. 3, fig. 1*).—A brief description is given of a lantern trap which captured 24,492 insects in a single night when exposed in a cotton plantation in Texas. Among this collection of insects 13,113 belonged to injurious species. In the lantern a mixture was burned containing white pitch, turpentine, linseed oil, and olive oil.

Nursery fumigation, C. FULLER (*Natal Agr. Jour. and Min. Rec., 8 (1905), No. 6, pp. 533-540, figs. 10*).—The fumigation of nursery stock before delivery by the nurserymen is recommended as a good practice. For the nurserymen's use it is recommended that the fumigation house should be a permanent structure of wood, iron, or brick lined with gas-tight material located some distance from dwelling houses and subjected, at least once every six months, to a test of its gas-retaining power. Directions were given for the preparation and application of hydrocyanic-acid gas.

Experiments with fumigating nursery stock, T. B. SYMONS and A. B. GAHAN (*Maryland Sta. Bul. 105, pp. 11-34, figs. 5*).—The experiments reported in this bulletin were undertaken for the purpose of determining the effect of hydrocyanic-acid gas upon nursery stock. This remedy is believed to be the most reliable one for destroying San José scale on nursery stock and it, therefore, becomes important to determine whether or not the treatment is injurious to trees.

During the experiments 3,000 trees were treated, one-half in the fall and the other half in the spring. The fall treatment was given on October 15 and the spring treatment on April 7. Both peach and apple trees were used in these experiments and a detailed record of these experiments is presented in a tabular form. In some cases apparent injuries by the gas would perhaps be attributed to other agencies, such as unfavorable soil conditions after the trees were set out.

The amount of cyanid per cubic foot varied from below the usual quantity to 6 times the amount ordinarily recommended for fumigating nursery stock. One-half the

trees were fumigated in 30 minutes and the other half in 60 minutes. Where an excessive amount of cyanid was used in an exposure of 60 minutes several trees were killed by the gas. As a rule, however, the percentage of trees which died was no greater than is ordinarily the case in orchard planting.

In the fall experiments, peach trees appeared to be more resistant than apple trees. This was not true, however, in the spring work. Some varieties of apple, for example the Yellow Transparent, were more resistant than others. The authors conclude from these experiments that no injury occurs as a result of fumigating dormant apple and peach nursery stock 2 years or more of age with the usual strength of hydrocyanic-acid gas. Apparently fumigation in the fall with an excessive strength of cyanid is more likely to produce injury than in the spring.

Orchard fumigation with hydrocyanic-acid gas, C. FULLER (*Natal Agr. Jour. and Min. Rec., 8 (1905), No. 7, pp. 697–715, figs. 11*).—Detailed directions are given for the combination of chemicals to produce hydrocyanic acid, the use of tents and other apparatus for confining the gas, and the application of the method, particularly to citrus trees. The results of experiments along this line are briefly summarized and recommendations made in accordance with investigations already published in this and other countries.

Spray calendar (*Bien Rpt. Bd. Hort. Oregon, 8 (1905), pp. 49–74*).—The purpose of this as of other similar spray calendars is to make recommendations regarding the questions when to spray, what to spray with, and how to spray. Some of the more important insect and fungus pests are described for the information of fruit growers and standard insecticides and fungicides are suggested for the control of these pests.

Bee culture, J. S. GILFILLAN (*Ann. Rpts. Bd. Ag. Del., n. ser., 3–4 (1903–4), pp. 129–134, figs. 4*).—The social organization of bees is briefly discussed with notes on various bee products. The value of bees is considered from the standpoint of honey production and fertilization of fruits and other plants Brief directions are given for the care and management of bees.

Sericulture in Madagascar, E. PRUDHOMME (*Agr. Prat. Pays Chauds, 5 (1905), Nos. 25, pp. 311–325; 26, pp. 389–402; 28, pp. 50–65; 30, pp. 212–229, figs. 9*).—An elaborate review is presented of the present status of sericulture in Madagascar. Sericultural education is briefly discussed.

Detailed directions are given regarding the cultivation of mulberries of various varieties and their use in feeding silkworms. The diseases of silkworms are considered and notes are given on their insect enemies. A historical account is presented of the different races of silkworms and the comparative merit of races and various crosses. The influence of the selection in breeding silkworms is also briefly considered.

Diseases of the silkworm and means of combating them, G. GANDARA (*Com. Par. Agr. [Mexico], Circ. 21, pp. 16, figs. 8*).—The common diseases of the silkworm are described and notes are given on their economic importance and means of combating them.

FOODS—HUMAN NUTRITION.

Food adulteration in Arkansas, J. H. NORTON (*Arkansas Sta. Bul. 88, pp. 77–118*).—With a view to determining the extent of food adulteration in the open market the station has collected and examined 354 samples of canned vegetables and fruits, catsups, dairy products, jams and jellies, baking powders, vinegar, soda water sirups, etc. Of these 166, or 47 per cent, were adulterated or sophisticated.

The bulletin contains, in addition to the analytical data reported, a discussion of the importance of pure foods and what has been done to secure them, and also includes an article by R. R. Dinwiddie on preservative drugs found in foods, which discusses their physiological effect and similar topics.

Report of the State food commissioner of Illinois, A. H. JONES (*Ann. Rpt. State Food Comr. Ill., 2 (1901), pp. 258, figs. 8*).—This volume contains the report of

the State analyst, the report of the State food commissioner, a compilation of laws and rulings under the law, and other data connected with the food inspection work. The total number of foods examined, including spices, baking powders, cocoa, candies, flour, sirup, dairy products, etc., was 980, of which 338 or 37.5 per cent were adulterated.

Analyses of food products, W. W. P. McCONNELL (*Bien. Rpt. Minn. State Dairy and Food Comr., 10 (1905), pp. 142–328, 380–427*).—Details are given regarding the examination, under the provisions of the State pure-food law, of a large number of samples of baking powders, dairy products, jams, jellies, meats, flavoring extracts, milk and cream, etc.

Report of State chemist, J. HORTVET (*Bien. Rpt. Minn. State Dairy and Food Comr., 10 (1905), pp. 431–555, figs. 27, charts 3*).—The analyses made under the State pure-food law are discussed and data regarding court cases given. It is stated that 11,884 samples have been examined of which 3,756 were illegal.

Biennial report of the deputy food commissioner, W. F. THOMPSON and E. L. REDFERN (*Bien. Rpt. Deputy Food Comr. Nebr., 1904, pp. 53*).—Results of analyses of milk, vinegar, flavoring extracts, sirups, tomato catsup, cider, fruit products, canned goods, and a number of miscellaneous samples are reported and briefly discussed.

Nineteenth annual report of the Ohio dairy and food commissioner, H. ANKENEY (*Ann. Rpt. Ohio Dairy and Food Comr., 19 (1904), pp. 66*).—The report covers a year's work of the State dairy and food commission. The total number of samples examined was 2,394, of which 872 were adulterated or sophisticated. The samples examined included condiments, beverages, dairy products and other foods, spices, flavoring extracts, drugs, etc. Prosecutions were instituted on 132 adulterated articles.

The food inspector's handbook, F. VACHER (*London: The Sanitary Publishing Co., 1905, 4. ed., pp. 231, illus.; rev. in Lancet [London], 1905, II, No. 21, p. 1430*).—This volume is intended as a guide for the use of food inspectors and contains chapters on animal foods, fish, game, vegetables, etc., with a description of the appearance and character of the foods, so that those which are fit for food and those which should be condemned may be recognized. The question of food adulteration is also taken up.

The sanitary inspector's handbook, A. TAYLOR (*London: H. K. Lewis [1905], 4. ed., pp. 455, illus.; rev. in Lancet [London], 1905, I, No. 19, p. 1277*).—It is stated that this work has been thoroughly revised, illustrations have been added, and the text and index amplified. Various questions connected with sanitary inspection are discussed, and a synopsis is given of the public health laws of Great Britain. The book is designed to meet the needs of sanitary inspectors and those seeking to qualify for such appointments, and also to supply practical information to those interested in sanitary subjects.

Municipal food control manual, H. MESSNER (*Taschenbuch für die Lebensmittelkontrollorgane der Gemeinden. Vienna and Leipsic: Wilh. Braumüller, 1905, pp. 284; rev. in Österr. Chem. Ztg., 8 (1905), No. 10, p. 233*).—This volume is designed as a manual for those engaged in municipal food-control work.

Existing official laboratories and their utilization for the detection of food frauds and adulterations, A. C. GIRARD (*Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 7, pp. 847–853*).—A list is given of French official laboratories, which, in the author's opinion, can be made use of in an organized attempt to suppress food adulteration.

The detection of corn meal in sausage, H. KREIS (*Ber. Chem. Lab. Basel, 10 (1903); abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 9 (1905), No. 8, p. 473*).—Methods of detecting corn meal were tested, the best results being obtained with that of Mayrhofer.

Analyses of imported Messina and New South Wales grown lemons, F. B. GUTHRIE (*Agr. Gaz. N. S. Wales, 16 (1905), No. 3, p. 306*).—Analytical data obtained from 5 samples are reported.

Properties and composition of some typical flours, W. E. MATTHEWSON (*Trans. Kans. Acad. Sci., 19 (1903-4), pp. 78-80*).—The composition of 8 sorts of flour and the character of the gluten were studied. Baking tests were also made but are not reported in detail.

According to the author, the baking tests showed that soft wheat flour gave a more sticky dough than the others, and this quality, more or less characteristic of soft wheats, "is considered to be connected with gluten rich in gliadin." The results obtained show that although the gliadin-glutenin ratio may be important in certain cases it did not suffice to explain the observed differences in the flours examined and that further study was needed regarding the relationships between composition and bread-making qualities.

The chemical composition and nutritive value of wheat and flour, CHAPUS (*Bul. Agr. Algérie et Tunisie, 11 (1905), No. 7, pp. 141-147*).—The gluten and gliadin content as a means of judging the quality of flour is discussed and data on the subject summarized.

The condition of starch in stale bread, E. ROUX (*Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 7, pp. 832-836*).—Since it had been found that when paste is allowed to stand the starch is changed into amylocellulose, an insoluble nonsaccharifiable material which colors iodin yellow, the author made investigations to learn whether a similar change takes place when bread grows stale.

The conclusion was reached that this was not the case and that it could not be said that the starch material of stale bread had a different nutritive value from that of fresh bread.

Poisonous bread, A. YACHEVSKI (*Zemledyeletz, 1905, No. 1, pp. 11-15; abs. in Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 2, p. 249*).—Serious illness and sometimes death were noted in 1903 in various localities in Russia when bread was eaten made from local grown grain.

Ergot was found in some samples of grain and flour, but the poisonous properties were attributed to a fungus, *Fusarium roseum*. This fungus grows on rye in damp localities and wet seasons, and is apparently spread by rain, wind, and insects. Direct experiments made by Zhilyakov showed that the fungus would produce the poisonous properties noted in the bread.—P. FIREMAN.

Some causes of discoloration of canned mushrooms, J. SARTHOU (*Rev. Soc. Sci. Hyg. Aliment., 1 (1904), No. 7, pp. 853-860*).—Three sorts of discoloration were noted, namely, a darkened area, black specks of varying size, and a discoloration which extends to the whole of the can contents. The first and second are ascribed to chemical causes, and the last to the action of bacteria.

When mushrooms are sulphured and canned, the sulphurous acid, acting upon the metal of the can or upon the solder, may cause discoloration. Such chemical discoloration is regarded as harmless and, according to the author, may be remedied by soaking the mushrooms a short time in a weak solution of acetic, citric, or tartaric acid and washing in plenty of water. The bacterial discoloration is an accompaniment of putrefactive fermentation, and is characterized by the odor of hydrogen sulphid. Such canned mushrooms are unfit for use.

Concerning certain adulterations of lard, A. OLIG and J. TILLMANS (*Ztschr. Untersuch. Nahr. u. Genussmtl., 9 (1905), No. 10, pp. 595-597*).—Notes on a sample of lard adulterated with cotton-seed oil, flour, and paraffin.

The quality of commercial cream of tartar, L. D. HAVENHILL (*Trans. Kans. Acad. Sci., 19 (1903-4), pp. 66-68*).—The examination of a number of samples of cream of tartar sold in Kansas showed that a considerable proportion of the samples

purchased in grocery stores were adulterated with calcium acid phosphate and its accompanying impurities. In some cases little or no cream of tartar was present. The samples purchased from druggists were found to be pure.

Examining and judging ground black peppers, E. SPAETH (*Ztschr. Untersuch. Nahr. u. Genussmtl., 9 (1905), No. 10, pp. 577–595*).—A summary of data regarding pepper analyses.

Concerning the analysis of wine vinegar, A. FROEHNER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 9 (1905), No. 6, pp. 361–363*).—The author concludes that lactic acid may be regarded as a normal constituent of wine vinegar and that a determination of the amount present may serve as a means of judging of the quality of the product.

Standards of purity for fermented and distilled liquors, P. SCHIDROWITZ (*Jour. Soc. Chem. Indus., 24 (1905), p. 176; abs. in Jour. Amer. Chem. Soc., 27 (1905), No. 6, Rev., pp. 352, 353*).—Various questions connected with standards of purity are discussed. The adoption of a single analytical factor as a standard of purity of any article is not considered advisable owing to the ease with which such a factor may be changed so as to come within requirements.

Sterilized fruits (*Jour. Jamaica Agr. Soc., 9 (1905), No. 1, p. 22*).—A note on the successful canning of mangoes, pineapples, bananas, akees, etc., by covering the fruit with cold sterilized water, sealing in bottles, and heating for 4 hours at 150° to 155° F.

The dietetic use of predigested legume flour, particularly in atrophic infants, D. L. EDSALL and C. W. MILLER (*Amer. Jour. Med. Sci., 129 (1905), pp. 663–684; abs. in Jour. Amer. Chem. Soc., 27 (1905), No. 6, Rev., p. 347*).—The data reported have to do with bean flour in which the starch is predigested by means of a diastatic ferment.

The diet in typhoid fever, J. B. NICHOLS (*Reprinted from Amer. Med., 9 (1905), No. 18, pp. 726–736*).—In this paper, based on the author's experience and that of others, a generous diet in typhoid fever is advocated. The results of a number of digestion and metabolism experiments reported by different investigators are summarized and discussed.

The use of copper in destroying typhoid organisms and the effects of copper on man, H. KRAEMER (*Amer. Jour. Pharm., 77 (1905), No. 6, pp. 265–281*).—On the basis of his own investigations and those of others the author recommends the use of small amounts of copper for the destruction of typhoid organisms in water, and states that he has obtained very satisfactory results by placing a piece of carefully cleaned copper foil 9 in. square in a vessel holding 3 to 4 qts. of water and allowing it to remain 4 to 8 hours. If the water contains a large amount of sediment, it is desirable to filter before treating with the copper foil. Such water has been used for over 6 months without any noticeable ill effects.

Believing that vegetables may be a source of typhoid infection, the author recommends washing those which are to be eaten raw in copper-treated water or placing them, especially lettuce and celery, in a vessel of water with a strip of copper foil and allowing them to remain from 2 to 4 hours with occasional agitation. "The use of copper vessels would be more convenient, but of course is more expensive."

Some of the author's general conclusions follow: "While exceedingly minute quantities of copper in solution are toxic to certain unicellular organisms, as bacteria, it is safe to assume that the higher plants and animals, including man, are unaffected by solutions containing the same or even larger amounts of copper. There being a number of factors which tend to eliminate copper from its solutions, it is hardly likely that there would be any copper in solution by the time the water from a reservoir reached the consumer if the treatment of the reservoir were in competent hands. Many plants contain relatively large quantities of copper, and when these are used as food some of the copper is taken up by the animal organism, but there are no records of any ill effects from copper so consumed."

The article contains a summary showing the amount of copper which has been reported in fruits, vegetables, and other food products, as well as bibliographical data on the subject.

Diet in health and disease, J. Friedenwald and J. Ruhräh (*Philadelphia and London: W. B. Saunders & Co., 1905, p. 689, figs. 4*).—In this volume, which the authors state is prepared to meet the needs of general practitioners, hospital internes, and medical students, and also to serve as a reference handbook for training schools, the chemistry and physiology of digestion are treated of at some length, as well as the different classes of foods, beverages, and condiments, and the concentration of food, the preservation of food, and other factors which bear upon diet.

Sections are devoted to infant feeding, diet for the aged, and other special conditions, etc., and special methods of feeding are discussed. More than half of the volume is taken up with discussions of diet in relation to disease and there is also a special section on institution dietetics and a short bibliography.

Nutrition and malnutrition, W. H. Allchin (*Lancet* [*London,*] *1905, I, Nos. 17, pp. 1111–1117; 18, pp. 1180–1184; 19, pp. 1250–1254; 20, pp. 1319–1326*).—A general summary and discussion of data on the digestion and absorption of different nutrients, and related questions under normal and abnormal conditions.

Standardized gruels, H. D. Chapin (*Med. Rec.* [*N. Y.*], *67* (*1905*), *No. 7, pp. 246–248, 275*).—In a paper presented before a meeting of the New York Academy of Medicine, January, 1905, the importance of gruels in infant and invalid dietetics is spoken of and directions given for the preparation of standard gruels of uniform composition.

Determinations of the total solids and protein in plain gruels made from barley, wheat flour, and rolled oats, and dextrinized gruels made from rolled oats and wheat flour are reported, the analyses having been made by the New York State Experiment Station. The author points out the high nutritive value of the vegetable proteids when given in the form of gruels. The paper was followed by a discussion.

The comparative influence of organic phosphorus compounds on nutrition, and the development and composition of animal tissues, A. Desgrez and A. Zaky (*Rev. Soc. Sci. Hyg. Aliment., 1* (*1904*), *No. 7, pp. 825–831*).—Experiments on animals were made with lecithin, nuclein, nucleic acid, and protylin, which led to the conclusion that these bodies increase the gains in body substance, especially protein, and favor rapid growth and the rapid accumulation of mineral matter in the skeleton.

The peptic cleavage products of the artolin, a proteid of wheat gluten, Hayashi (*Arch. Expt. Path. u. Pharmakol., 52* (*1905*), *No. 3–4, p. 289; abs. in Zentbl. Physiol., 19* (*1905*), *No. 4, p. 103*).—When treated for a short time with pepsin-hydrochloric acid, artolin yields an albumose-like body, "artose," which has the same composition as artolin, but a higher water content. When the action is continued for a longer time, parartose and metartose are obtained and the cleavage product artolin-antipeptone which contains no sulphur and 3 cleavage products of parartose containing sulphur, namely, protoartose, heteroartose, and deuteroartose.

Course of wholesale prices, 1890 to 1904 (*Bur. of Labor* [*U. S.*] *Bul. 57, pp. 389–549, dgms. 4*).—Food and food products constitute one of the groups included in the statistical investigation reported.

ANIMAL PRODUCTION.

Energy values of red clover hay and maize meal, H. P. Armsby and J. A. Fries (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 74, pp. 64, dgms. 3*).—Following methods outlined in an earlier report (E. S. R., 15, p. 1037), respiration calorimeter experiments were made with a steer in which 4 rations were tested in different periods.

The rations consisted of an amount of clover hay estimated to be somewhat less than sufficient for maintenance (5,200 gm.); a considerably smaller amount of clover hay (3,700 gm.); a small amount of clover hay (3,700 gm.) supplemented by a quantity of maize meal (850 gm.) calculated to be sufficient to make the total ration somewhat less than adequate for maintenance; and the same amount of clover hay supplemented by maize meal enough (4,000 gm.) to provide a ration sufficient for moderate gain.

The comparison between the first and second periods gives data for determining the net availability of the energy of the clover hay, and the results of the second and third periods for computing the energy of maize meal, while the data of the fourth period affords a means of ascertaining the percentage utilization of the energy of maize meal in the production of gain. Each experimental period covered 21 days, of which the first 11 were regarded as preliminary, and the digestibility of the ration and the income and outgo of matter and energy were measured.

From the experimental data, which are recorded in full, it appears that the coefficients of digestibility of the dry matter and total protein of the more abundant ration of clover hay were 59.13 and 48.58 per cent, respectively, and for the smaller clover-hay ration 59.70 and 53.19 per cent. In general, the smaller ration was more thoroughly digested, but the authors consider the differences small enough to be within the limits of error.

When maize meal formed a part of a ration scarcely sufficient for maintenance, the coefficients of digestibility of dry matter and protein were 87.34 and 85.23 per cent, respectively, and in the productive ration 91.50 and 62.30 per cent. The values for proteids in the 2 rations were 80.14 and 66.43 per cent. "The results obtained upon total protein and proteids seem to indicate a decrease in the apparent digestibility of these constituents under the influence of the large supply of carbohydrates in the maize meal."

In discussing energy values the authors point out that—

"The relation of the metabolizable energy to the amount of matter in the food may be expressed in terms of calories per gram of the total or of the digested organic matter. . . .

"The metabolizable energy of a feeding stuff may also be expressed as a percentage of the total or gross energy. Such a percentage is analogous to a digestion coefficient, so that if an average value for it were established for any particular kind of feeding stuff, the amount of metabolizable energy in a given amount of it could be computed from its total energy by multiplication by this coefficient just as the digestible dry matter or organic matter can be computed from the total amount present by the use of a digestion coefficient."

In the case of the clover hay it was found that the metabolizable energy constituted 42.58 per cent of the total energy in the first period, and 44.22 per cent in the second period, or 43.40 per cent on an average. Calculated as a percentage of the energy of digested matter, the values were 75.52 for the first period and 76.18 for the second period, or 75.85 per cent on an average. In the case of the maize meal the metabolizable energy was 64.16 per cent of the total energy on the limited ration and 77.68 per cent on the more abundant ration. When the calculations are based upon the energy of digested matter, the values are 75.06 and 85.53 per. cent, respectively.

"The above results represent what has been called the 'apparent' metabolizable energy. It is not at all unlikely that the addition of maize meal affected to a greater or less degree the digestibility of the hay to which it was added.

"In particular, . . . it seems possible that it diminished the digestibility of the protein of the total ration.

"If such was the case, the results . . . [noted] above are too small to represent the actual metabolizable energy of maize meal, just as the corresponding results upon the

digestibility of the protein are too small. In the one case as in the other our figures represent the net effect upon the amount of metabolizable energy or of protein which the animal derived from its ration. Any effect of one ingredient of the ration upon the digestibility of the other is ascribed, by the method of computation employed, entirely to the maize meal. The results, therefore, as stated, represent the apparent digestibility or the apparent metabolizable energy."

A considerable portion of the metabolizable energy of food, it is pointed out, may be consumed in the chemical and mechanical processes incidental to the digestion of food and its conversion into forms fitted to nourish the body, or may be otherwise converted into the form of heat and so not be directly available to make good the losses of potential energy from the body caused by the vital processes. The portion of the metabolizable energy remaining after deducting the quantity thus expended represents the net contribution which the food has made to the maintenance of the stock of potential energy in the body, and may be designated as net available energy. The average value deduced for red clover hay and the value for corn meal in a productive ration were 36.42 and 77.81 per cent, respectively.

"While this result is subject to the errors involved in the determination of the metabolizable energy of the maize meal, it is nevertheless evident that the energy of the latter is far more available than is that of either clover or timothy hay. Expressed in another way, this is equivalent to saying that the expenditure of energy in digestion and assimilation is relatively less in the case of maize meal -a result which was to have been anticipated from the nature of the material."

From the data presented, the authors calculate that the clover hay supplied 2,058 calories of the metabolizable energy per kilogram of total organic matter on an average and maize meal in a productive ration 3,441 calories. For available energy the calculated values were 750 calories per kilogram total organic matter for clover hay on an average and 2,678 calories for maize meal in a productive ration.

The authors' discussion of the differences between fuel value, values for maintenance, and productive processes, as exemplified by these experiments, has been noted from another publication (E. S. R., 17, p. 380).

Weathered hay, W. F. SUTHERST (*Chem. News, 92 (1905), No. 2385, p. 61*).—Part of a field of uncut hay was protected with canvas during 2 days of wet weather and samples of the protected hay and that which was not so protected were analyzed.

The dry matter of the protected hay had the following percentage composition: Water 15.65, protein 16.52, carbohydrates 39.14, crude fiber 28.91, and ash 5.43 per cent. The dry matter of the weathered hay had the following percentage composition: Water 12.75, protein 14.58, carbohydrates 37.14, crude fiber 33.32, and ash 4.96 per cent.

The larger proportion of water in the protected hay, in the author's opinion, is due to the fact that the gummy material in the hay, which would be the first to be washed out, is hygroscopic and attracts atmospheric moisture. The loss of nitrogenous material in weathered hay is not regarded as serious, since this material would largely consist of soluble nitrogenous bodies (amido compounds) whose feeding value is small.

Digestion coefficients of alfalfa, H. G. KNIGHT (*Ranchman's Reminder, 2 (1905), No. 5, pp. 36–39, fig. 1*).—In experiments with sheep carried on at the Wyoming Experiment Station the following average coefficients of digestibility were obtained with second cutting alfalfa: Dry matter 63.4, protein 79.7, fat 41.1, nitrogen-free extract 74.2, crude fiber 44.6, and ash 56.2.

Condimental stock and poultry foods, J. B. LINDSEY ET AL. (*Massachusetts Sta. Bul. 106, pp. 24*).—The results of chemical and microscopical examinations of 65 samples of stock foods, poultry foods, and condition powders are reported, the goods being secured in most cases from fresh stock and unbroken packages.

The basic ingredients of these materials were generally such well-known concentrated feeds as corn meal, wheat offal, and linseed meal, though in some instances some substance like mustard hulls was used. The medicinal ingredients were found to consist of some of the more common drugs, including fenugreek, fennel, anise, gentian, ginger, pepper, salt, magnesium and sodium sulphates, saltpeter, sodium bicarbonate, sulphur, iron oxid, charcoal, and turmeric.

The wholesale cost of the mineral drugs, except niter, it is pointed out, is not over a cent a pound, while that of the vegetable drugs varies from 3 to 12 cts. a pound, and judging from available data the original cost of the entire mixtures could rarely have exceeded 2.5 to 3 cts. per pound and in many cases could not have been over 2 cts. The retail price of the stock and poultry foods varied from 6 to 25 cts. a pound, depending on the brand and quantity purchased. The condition powders were much higher, ranging from 30 cts. to $1 per pound. The great economy of homemade mixtures of common drugs, etc., is pointed out.

The food value of stock foods and condition powders "has been shown to be no greater than that of the ordinary grains of which they are largely composed. Their medicinal value depends largely upon the aromatic seeds and roots used as a tonic for the stomach, on charcoal as an absorbent, and on the purgative effect of the Epsom or Glaubers salts. The quantity recommended to be fed daily is usually so small (1 oz. or less) that very little effect can be expected unless the material is fed for a considerable length of time. While it is probably true that some of these stock foods may prove beneficial under certain conditions, it is also true that most of them are heterogeneous mixtures and evidently put together by parties quite ignorant of the principles of animal physiology, pathology, and veterinary medicine."

A résumé of experiments with stock and poultry foods is also given, and the results of a demonstration test of the relative value of Pratt's food and a mixture of corn meal and wheat middlings is reported. Four cows, divided into 2 lots of 2 each, were fed a basal ration of fine-cut hay, rowen, distillers' grains, and middlings. In addition, one lot was given daily 0.5 to 0.75 lb. each of Pratt's food, and the other a like amount of the grain mixture mentioned. After a month the special rations were reversed.

Considering the test as a whole, there was a gain of 12 lbs. on the ration containing Pratt's food and 20 lbs. on the mixture of corn meal and wheat middlings. The total milk yield of the 2 lots was 3,048.2 lbs. and 2,998.07 lbs., respectively. With Pratt's food the milk showed on an average 13.51 per cent total solids and 4.58 per cent fat, and on corn meal and wheat middlings 13.45 per cent total solids and 4.54 per cent fat.

According to the authors, the investigations show that Pratt's food did not substantially increase the quantity of milk and milk ingredients over that produced by a like amount of ordinary feeds, as the slight variation noted was within the limits of experimental error. The condimental feed also failed to increase the richness of the milk, although it increased the cost of milk and butter fully 10 per cent. No effects, favorable or otherwise, on the general health and condition of the animals were noticed when the condimental feed formed a part of the daily ration.

The bulletin also contains brief notes of the examination under the law of 481 samples of concentrated feeds collected during the winter and spring of 1905. Though the analyses are not reported in full, some general deductions are drawn. Among other points it was noted that the cotton-seed meal was quite generally of good color and of satisfactory mechanical condition, though in many instances there was a tendency to reduce the minimum protein guarantee to 41 per cent or lower, which would indicate that the highest grade meal was not being offered. Several samples of Sea Island cotton-seed meal contained only 25 per cent protein, and consequently would be actually worth only about half the price of goods of prime quality.

Many of the wheat by-products examined were found to contain an undue amount of screenings and quite often corn, the amount of the latter being from a trace to some 30 per cent. Inferior wheat was also sometimes found. The molasses feeds usually met their guarantees, but the authors do not consider them to be as economical as high-grade protein by-products. The data regarding the poultry feeds examined were included in a bulletin previously noted (E. S. R., 16, p. 903).

Analysis of commercial feeding stuffs sold in Maryland, H. B. McDonnell et al. (*Md. Agr. Col. Quart., 1905, No. 28, pp. 11*).—Under the provisions of the State feeding-stuff law analyses were made of blood meal, meat meal, and similar goods, cotton-seed meal, linseed meal, flaxseed meal, granulated milk, gluten meal and feed, malt sprouts, corn-oil-cake meal, mixed and proprietary feeds, poultry feeds, bran, cotton-seed feed, dried molasses beet pulp, and dried sugar beet pulp.

The nutritive value of dried grape pomace, S. Weiser (*Weinlaube, 1904, pp. 453–455; abs. in Centbl. Agr. Chem., 34 (1905), No. 3, pp. 190–192*).—Analyses of dried grape pomace are reported and its feeding value discussed.

Phosphate of lime in the feeding of farm animals, J. P. Wagner (*Jour. Soc. Cent. Agr. Belg., 52 (1905), No. 8–10, pp. 268–281*).—From a summary of available data the conclusion is reached that the importance of phosphate of lime for the formation of bone and for the digestion and assimilation of food is generally recognized. Under ordinary circumstances the rations fed supply a sufficiency of this material. If, for any reason, this is not the case and mineral salts must be resorted to precipitated calcium phosphate of known purity should be used.

Present methods of beef production, III, H. W. Mumford and L. D. Hall (*Illinois Sta. Circ. 91, pp. 4*).—Information regarding pigs following cattle in the feed lot is summarized, the data as in the case of previous publications (E. S. R., 16, pp. 805, 1112) being based upon replies received from a large number of Illinois cattle feeders in answer to a circular letter of inquiry.

Of the 509 cattle feeders who furnished data on the subject, 90 per cent kept pigs with cattle when on feed, and 70.7 per cent of those who stated a preference as to breed favored Poland-Chinas. Whatever the breed, pigs 6 months old or those weighing on an average 125 lbs. were generally preferred, and 56 per cent of the feeders allowed 1 pig to each steer. Eighty-three per cent of those who keep pigs with their cattle fed corn in addition to the feed which they could gather. Nine per cent of the correspondents who replied stated that they secured less than 1 lb. of gain per head per day when no additional corn was fed to the pigs, 42.5 per cent secured a gain of 1 lb. per head per day, and 49 per cent more than 1 lb. With reference to the proportion of the corn fed to the cattle which should be charged to the pigs following them, three-fourths of the correspondents stated that one-fifth to one-third should be charged to the pigs.

Oil meal when fed to steers is often said to have a beneficial effect on the pigs following them. Thirty-seven per cent of those who furnished data on this point noted an advantage, while the remaining 63 per cent did not. Forty per cent of the feeders had found that cotton-seed meal fed to cattle is injurious to the pigs following them, while 60 per cent had noted no injurous effects. A small number of the correspondents mention other supplementary feeds (usually condimental stock feeds) which, in their opinion, have given as good results as oil meal.

"One of the most successful feeders states in his report that he has used successfully a self-feeding box in supplying mineral substances to the hogs. Wood ashes are mixed by the wagonload with salt, copperas, and sulphur, and placed in a small self-feeder similar in construction to those used for cattle."

Only 8 per cent of the correspondents furnish permanent houses for their pigs, while practically all the remainder furnish no shelter except that afforded by the sheds and barns provided for the cattle.

Present methods of beef production, IV, H. W. MUMFORD and L. D. HALL (*Illinois Sta. Circ. 92, pp. 8*).—Continuing the above-mentioned work, information was collected regarding feeds and their preparation.

As regards the production and purchase of feeds, only about 10 per cent of the feeders who replied raise all the feed which they use in the production of beef. About 50 per cent purchase corn and 50 per cent other commercial feeds, linseed-oil meal being the most important feed besides corn.

As regards the methods of feeding the corn crop, 24 per cent of the 197 replies on this point were in favor of shock corn, 25 per cent in favor of shock corn combined with corn otherwise prepared, 13 per cent in favor of shredded corn and corn otherwise prepared, and 11 per cent in favor of shredded corn fodder alone.

"Eighty per cent either pasture the stalks in the field or cut part for shock corn and pasture the remainder, 12 per cent plow under all the stalks, and the remainder either burn them or convert them into silage. Only 5 correspondents state that they cut the entire crop of corn."

Linseed meal was fed by 21 of those who supplied data, the highest amount mentioned being 6 lbs. per head per day and the lowest (for young cattle) 0.2 lb. The average for all kinds of cattle was 2.2 lbs., and for fattening steers 3 lbs. Ten per cent of the replies mention the use of bran, 5 lbs. per head per day being the average amount, 13 lbs. the maximum, and 1 lb. the minimum. Cotton-seed meal was fed by 7 per cent of the correspondents, the largest amount being 9 lbs. and the smallest 1 lb. per head per day, or an average of 4.1 lbs. Only one correspondent spoke unfavorably of it.

The data gathered indicate that condimental preparations or "patent stock foods" are purchased by 7 per cent of the Illinois cattle feeders. "The advantages claimed for them by those who comment on the results secured are that they increase the amount of feed consumed, aid digestion, and give gloss to the hair. A large proportion of those who buy such preparations use them only for young stock or breeding cattle."

Oats are used by only about 3 per cent of the feeders, and various other grains and concentrated feeds, viz, gluten meal, gluten feed, hominy hearts, "shipstuff," cottonseed hulls, shorts, middlings, flaxseed meal, and brewers' grains are used by about 9 per cent of all the correspondents.

Data were also gathered as to the kind of coarse fodder used in full feeding, the kind of pastures preferred, their management, amounts of pasturage required, use of salt, practice of warming drinking water in winter, and related topics.

"Summarizing the reports concerning the daily gain in weight of cattle during the whole grazing season on grass alone, we find the average of all replies for 2-year-old cattle to be 1.87 lbs. per day. The greatest daily gain reported is 3 lbs., and the smallest 1 lb., but 80 per cent of the reports name amounts from 1.5 to 2.5 lbs. The average of all replies for yearlings is 1.66 lbs. per day. The greatest gain mentioned is 3 lbs., and the smallest 1.5 lbs."

Present methods of beef production, VI, H. W. MUMFORD and L. D. HALL (*Illinois Sta. Circ. 98, pp. 15, figs. 9*).—Continuing the summary of data based on replies received from some 500 cattle raisers (E. S. R., 17, p. 384), the importance of shelter and the need of improvements in feed lot conditions are considered.

The replies received from cattle raisers indicate that only a very small percentage have naturally drained lots or take any precautions to prevent mud and its attendant discomfitures and disadvantages. Of the 36 cattle feeders who report definite provisions against mud, 10 have paved or otherwise artificially covered the surface of the feed lot; 15 use rock, gravel, cinders, bricks, planks, corn cobs or sawdust, alone or in combination, in various parts of the lot, for instance, about the feed troughs, water tanks, sheds, or gates; 10 have put the lots in satisfactory condition by tiled draining, while 2 grade the yards and clean out the mud and manure with dirt

scrapers. Several of those who use coal cinders for filling muddy portions of the lot state that they should be covered with straw, cornstalks, or other bedding material in order to prevent injury to the feet of the cattle.

The authors note the wide divergence of opinion among practical feeders as to the kind and amount of shelter necessary for fattening cattle. About half the correspondents state that sheds are used; about one-third, including most of those who feed in spring and summer, use pens, lots, or open fields, where cattle usually have access to shade of one sort or another; and about 10 per cent feed in barns. Two individuals state that they practice stall feeding, while a few depend upon woods and straw stacks for shelter.

A few feeders report that they find the shelter unnecessary even in winter. Two-thirds of the correspondents stated that in their opinion better results would be obtained if the steers had access to a closed shed or warm barn and in many cases point out that the barn or shed should be well ventilated and lighted, and that the steers must not be confined too closely. Twenty-eight of the reports, principally those from large feeders, state that self-feeders are used and practically all who discuss the advantages of this plan of feeding point out either the saving of labor or the advantage of uniformly regulated feed.

The circular also contains brief descriptions of cattle yards, feeding and watering devices, cattle shelters, and a self-feeder which experience has shown to be satisfactory.

Flaxseed for fattening lambs, G. E. MORTON (*Ranchman's Reminder, 2 (1905), No. 3, pp. 19, 20, figs. 2*).—In a comparison of ground flaxseed and barley fed with alfalfa and turnips to lambs, it was found that on flaxseed the average gain in the 16 weeks of the test was 26 lbs. per head and on barley 33 lbs. The cost of a pound of grain was, however, greater on the barley than on the flaxseed ration.

The test as a whole is regarded as satisfactory since it shows that "raw flaxseed may be used successfully without cereal grains or corn in finishing lambs for market." Apparently flaxseed increased the flow of urine, as has been thought to be the case. The manure, however, was not of abnormal consistency.

Bacon pigs in Canada, J. H. GRISDALE (*Canada Cent. Expt. Farm Bul. 51, pp. 61, pl. 1, figs. 4, dgms. 8*).—Breeds, housing, feeds and feeding, care and management, causes of soft pork, and related questions are discussed, the work as a whole summarizing the investigations of the Canada experiment stations, particularly the Central Experimental Farm.

Very good results are reported from Manitoba when sows and breeding stock generally were wintered in pens constructed of a low framework of poles on posts covered with a large amount of straw, the entrance on the south side being a passage of similar construction to the pen. The pigs were, of course, fed outside the pens. It is said that with a temperature of 30° F. below zero the pigs remained in good health.

The various investigations which are summarized have been noted from time to time as they have appeared in the publications of the Canada experiment stations.

The effect of body movement upon the digestion and absorption of nutrients in the horse, A. SCHEUNERT (*Arch. Physiol. [Pflüger], 109 (1905), No. 3-4, pp. 145-198*).—The horses were fed under uniform conditions. In some of the tests they were allowed to rest for 1 to 5 hours after feeding, and in others they were driven for like periods. They were then slaughtered and the contents of the digestive tract examined with a view to determining the effect of muscular work on digestion and assimilation of nutrients.

In general, the conclusion was reached that body exercise considerably increased digestion and assimilation of the nutrients of food. The passage of stomach contents into the intestine begins very soon, probably while the food is being eaten, and is accelerated by exercise. Exercise increases the amount of gastric juice, and also its enzym and hydrochloric-acid content.

The daily ration of work horses, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 10 (1905), No. 36, pp. 297, 298*).—The changes which have been made in the rations of the Paris Omnibus Company's horses, the average value of the rations, and related topics are briefly spoken of. (See E. S. R., 16, p. 587.)

Examination of horses for soundness, G. H. ROBERTS, edited by A. W. BITTING (*Indiana Sta. Bul. 109, pp. 35–76, figs. 34*).—In this bulletin, which is the result of joint work between the State veterinarian and the station, the object has been to give concise and clear directions for the systematic examination of horses, to point out conditions that should be present in soundness and the diseases and defects that may be looked for in different parts of the body, and to call attention to vices which may be expected.

Different parts of the body are described, and the explanations and suggestions given are exemplified by numerous reproductions of photographs. The bulletin as a whole is designed to supply useful information to those who desire to purchase horses for various reasons.

"The horse is sound when he is healthy and when his conformation is such that he has not had and is not likely to have any tendency to any particular diseases. . . .

"An animal may have had diseases that have been cured, or may have some disease at the time of examination that does not interfere with his usefulness for some purposes, is then said to be 'serviceably sound.' In some places 'serviceably sound' refers only to wind.

"A vice is not necessarily unsoundness, but some of them lead to unsoundness and may therefore be considered as part of the examination in the selection of an animal. Vices are such traits of character, or such habits as have the tendency to produce disease or to lessen the usefulness, mar the appearance, interfere with, or make dangerous, the handling, or cause the destruction of property. Before examining the horse, the purchaser should decide upon the character of the service for which the animal is intended, whether for slow draft, heavy or light harness, saddle, or combination. The class or type, size, age, gait, sex, and color should be approximately settled. Ample time should be taken in the selection of a horse. This can usually be done when the animal is obtained from the dealer or producer, but is seldom allowable at public sales or at sale stables. . . .

"The ideal conditions under which to examine the horse for soundness is at his home, first in the stable, next in the door, then outside the stable, and finally in action."

DAIRY FARMING—DAIRYING.

Distillers' dried grains v. cotton-seed meal as a source of protein, H. P. ARMSBY and A. K. RISSER (*Pennsylvania Sta. Bul. 73, pp. 11*).—In an experiment with 12 cows lasting 12 weeks a grain ration of 3.5 lbs. of corn meal and 5.5 lbs. of distillers' dried grains was compared with a ration of 6 lbs. of corn meal and 3 lbs. of cotton-seed meal.

The dried distillers' grains resulted in a slight increase in the yield of milk and a marked increase in the fat content of the milk, but was more costly than the cotton-seed meal ration at the prices assumed. The quality of the butter produced on the distillers' grains ration was inferior to that of the butter produced on the cotton-seed meal ration.

Report of the experiment station and dairy institute at Kleinhof-Tapiau, 1904–5, HITTCHER (*Ber. Vers. Stat. u. Lehranst. Molkw. Kleinhof-Tapiau, 1904–5, pp. 12*).—In this account of the work of the institution during the year are given the records of the dairy herd of about 120 cows. The average composition of the milk of the herd for 10 years was as follows: Fat 3.181, total solids 11.728, and solids-not-fat 8.547 per cent. The corresponding figures for the year were 3.145, 11.787, and 8.642.

Possibilities of profitable cows on the farm, A. J. GLOVER (*Ann. Rpt. Ind. Dairy Assoc., 15 (1905), pp. 56-66*).—This summarizes the results of farm tests of 10 dairy herds. Of 145 cows of which records for 2 years were obtained, the best cow produced 7,190 lbs. of milk and 428 lbs. of butter, and the poorest 4,560 lbs. of milk and 158 lbs. of butter. Somewhat detailed reports are given of two of the herds.

Investigations on the fat-free solids in fractional milkings, F. LAUTERWALD (*Milchw. Zentbl., 1 (1905), No. 9, pp. 385-400*).—The author discusses the data published by Swoboda (E. S. R., 16, p. 71) and others and reports original determinations.

When calculated in percentages of the fat-free milk or milk serum, the solids-not-fat were found in the great majority of cases to be constant in the different portions of the milking. The variations in the constituents of the solids-not-fat (casein, albumin, milk sugar, and ash) were of an unessential nature and, from a practical standpoint, entirely insignificant. The hope of obtaining by means of fractional milking a milk more nearly approaching human milk in composition, as, for instance, one richer in albumin, is, therefore, considered entirely without foundation.

On the relations between the method of milking and the composition of the milk, F. KRULL (*Mitt. Landw. Inst. Leipzig, 1905, No. 7, pp. 107-180*).—The literature of this subject is reviewed and original investigations are reported in detail.

Relations between the method of milking and the composition of the milk were found to exist only so far as the fat content of the milk from the different quarters of the udder was concerned. The percentage of the other milk constituents remained practically constant. Any increase in the yield of milk and fat by any particular method was considered only apparent, since lower results were obtained by the succeeding method employed.

Variations in the fat content of the milk observed when different methods were used were believed to be due to purely mechanical causes, principally the contractility of the udder, the amount of agitation, and changes in tension due to the removal of milk. Variations in the fat content of the milk bore no constant relation to the method of milking employed.

Sampling milk for composite tests of individual cows, H. A. HOPPER (*Illinois Sta. Circ. 90, pp. 5, fig. 1*).—Directions are given for this purpose.

The value of the nitrate reaction for detecting the adulteration of milk with water, J. ADORJÁN (*Ztschr. Landw. Versuchw. Oesterr., 8 (1905), No. 9, pp. 846-851*).—Observations on this subject are reported from which the author concludes that the nitrate reaction can not always be depended upon as an indication of watering, inasmuch as the presence of dirt in milk may give the reaction.

It may also be obtained when the milk cans are washed and not dried before using. Furthermore the addition of water free from nitrates can not be detected in this way. The method, therefore, can not be depended upon to give more than a suspicion of the existence of adulteration which should be confirmed by more accurate analytical data. The method is, therefore, suitable for use only by the analyst in connection with other methods.

On bodies in normal and pathological milk serum which react with β-naphthalin-sulphochlorid, R. STRITTER (*Milchw. Zentbl., 1 (1905), No. 10, pp. 444-447*).—The author was unable to identify positively the presence of an amino compound or a body reacting with β-naphthalin-sulphochlorid in the serum of normal milk, although it was considered probable that such a nitrogenous substance may have been present in extremely small quantities. Further experiments with the milk of diseased animals are in progress.

Investigations on the determination and the variation of casein in human milk, G. PATEIN and L. DEVAL (*Ann. Chim. Analyt., 10 (1905), No. 11, pp. 422-427*).

Determination of dirt in milk, H. WELLER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 10, pp. 591-596*).—The method used by the author consists in diluting 50 to 100 cc. of milk with an equal quantity of hot distilled water, filtering through a

weighed filter paper with the aid of a vacuum pump, and washing and drying the residue. This method was found to be rapid and accurate, comparing well with the methods of Renk and Stutzer.

Infantile mortality and milk depots, W. J. THOMPSON (*Dairy, 17 (1905), No. 203, pp. 352, 354*).—In this address statements are made concerning the success obtained by the Gouttes des Lait in France, and the infants' milk depots in England and other countries, and the establishment of such an institution in Dublin is urged.

The action of formaldehyde in the preservation of milk, F. D. CHESTER and T. R. BROWN (*Delaware Sta. Bul. 71, pp. 36*).—The questions studied included the effect of adding different proportions of formaldehyde to milk on the time required for the milk to sour, the number of colonies developing on agar plates, and the character of the bacterial flora.

The authors review briefly some of the literature of this subject, discuss the use of formaldehyde as a milk preservative, and from the experimental data presented draw conclusions which are quoted in full below. It may be noted that, as acknowledged by the authors, the position taken in the bulletin, as regards the use of formaldehyde in milk, is contrary to that generally held by medical men and sanitarians. To control bacterial development in milk by refrigeration is believed by the authors to be impracticable or too expensive at the present price of the product. It is predicted that about all that will ever be accomplished in controlling the milk supply will be the control of the more glaring abuses regarding production and handling.

Where an intelligent person is his own producer and consumer, it is believed that the best possible safeguard would be the refrigeration of the milk and its consumption within 24 hours of production. In the general trade, however, a temperature of 60° F. is believed to be safer, inasmuch as at this temperature the lactic-acid bacteria would develop at such a rate as to exclude, in a large measure, the dangerous bacteria, while the period from milking to souring would be sufficiently short to insure against too great an age of the product. Under such conditions it is also believed that the addition of formaldehyde in quantities not to exceed 1 part in 40,000 (or about 1 teaspoonful of 40 per cent formalin to 15 gal. of milk) would extend the keeping quality of the milk and improve its hygienic qualities.

The conclusions are as follows:

"(1) With different milks containing the same quantities of formaldehyde, the time of curdling varied within rather wide limits, dependent upon the character of the bacteria in the raw milk and upon slight variations of temperature.

"(2) With different milks containing different quantities of formaldehyde, the amount of formaldehyde bore no exact relation to the time of curdling.

"(3) With milk containing 1 to 2,000 up to 1 to 800 of formaldehyde there was a rapid decrease of bacteria during the first 24 hours, after which there was a slow decrease, until by the end of 5 days the milk was practically sterile, or contained only resistant spores.

"(4) With milk containing 1 to 5,000 of formaldehyde there was a rapid reduction of bacteria during the first 4 to 6 hours, but continuing throughout the entire 24, after which the bacteria continued to multiply at first very slowly, then at a very rapid rate.

"(5) With milk containing 1 to 10,000 of formaldehyde there was in some cases a slight reduction in numbers during the first 24 hours, followed by a very slow increase, then by a rapid increase. In others there was a very slow increase from the start, followed by a very rapid increase.

"(6) With milk containing 1 to 20,000 of formaldehyde there was a slow increase during the first 24 hours, followed by a rapid increase.

"(7) With milk containing 1 to 40,000 of formaldehyde the initial and later periods of increase were not differentiated, but the rise of bacteria was rapid from the start, but much less rapid than in the case of untreated milk.

"(8) Milk containing 1 to 40,000 of formaldehyde kept 2 to 3 times as long as untreated milk at the same temperature, and with 1 to 20,000 4 times as long.

"(9) When milk, containing formaldehyde, was kept at 25° C. (78° F.) there was a tendency on the part of the formaldehyde to restrain the development of the miscellaneous bacteria originally present in the raw milk, without a corresponding retardation of growth of the common lactic-acid ferment (*Bacterium acidilactici*).

"(10) *B. acidilactici* developed slowly in milk containing formaldehyde in proportions as high as 1 to 5,000, proportions sufficient to kill or entirely check the growth of other milk organisms.

"(11) Certain species of yeast were capable of growing in milk containing considerable proportions of formaldehyde, the yeast appearing first, followed by the lactic-acid fermentation.

"(12) Milk kept at 10° C. (50° F.) and containing formaldehyde in proportions as high as 1 to 10,000 remained uncurdled for a long time, but showed a large development of forms commonly found in raw milk.

"(13) The restraining action of formaldehyde was much less marked at refrigerating than at ordinary room temperatures.

"(14) With the presence of formaldehyde in milk kept at 25° C. (77° F.) the harmless lactic-acid bacteria were capable of growing better than other bacteria commonly found in milk. Hence the presence of formaldehyde, combined with normal room temperatures, is favorable to a harmless lactic-acid fermentation and unfavorable to a mixed fermentation liable to render the milk unwholesome.

"15. The presence in milk of small amounts of formaldehyde, not to exceed 1 part per 40,000, or 1 teaspoonful of 40 per cent formalin per 15 gal. of milk, and the holding of the milk at temperatures between 60 and 70° will improve its sanitary quality by preventing rapid and objectionable fermentations, and there is no reason to believe that in this proportion any marked injury could result to the person consuming it."

On abnormal butter, K. FISCHER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 6, pp. 335–339*).—Nine samples of butter made from the milk of several cows during periods when they were fed in the stable and also pastured showed Reichert-Meissl numbers varying from 15.4 to 23.6, saponification numbers from 205.5 to 215.3, iodin numbers from 39 to 47.3, Polenske numbers from 0.7 to 1.7, and molecular weights of the nonvolatile insoluble fatty acids from 267 to 272.2.

On the ripening of Edam cheese, F. W. J. BOEKHOUT and J. J. O. DE VRIES (*Centbl. Bakt. [etc.], 2. Abt., 15 (1905), No. 10–11, pp. 321–334; abs. in Rev. Gén. Lait, 5 (1905), Nos. 1, pp. 1–9; 2, pp. 25–33; 3, pp. 59–64*).—In experiments conducted during 4 years, attempts to secure the ripening of Edam cheese with lactic-acid bacteria isolated from cheese and cultivated on whey gelatin or cheese gelatin were unsuccessful.

In proportion to the content of water the exterior layer of fresh cheese contained 13.3 per cent of salt and the central portion 0.4 per cent. With cheese 4 weeks old the salt content of the exterior and interior portions was respectively 5 and 4.4 per cent, showing a gradual penetration of the salt from the exterior to the interior. Inasmuch as the ripening of Edam cheese is uniform throughout, salt is not, therefore, believed to exert any influence on the process.

The quantity of insoluble lime is considered of great importance in the ripening process, indicating as it does the quantity of lactic acid which will be fixed and the degree of acidity of the cheese at the end of the reactions, and ruling, therefore, one of the principal factors of ripening.

The volatile fatty acids were not found to increase during ripening. There was a marked decrease in the percentage of ammonia.

The chemical difference between casein and paracasein, W. LAQUEUR (*Abs. in Österr. Chem. Ztg., 8 (1905), No. 22, p. 521*).—The paracasein was found to contain

more carbon and hydrogen but about 0.8 per cent less nitrogen than the pure casein from which it was prepared. Rennet, therefore, produces a chemical change in the casein resulting in the production of paracasein and another nitrogenous body. Paracasein has the same acidity as casein, but is more readily precipitated by salts.

The principal products and by-products of milk, G. Rovesti (*Lavorazioni moderne del latte. Prodotti principali e sottoprodotti. Casale, 1905; rev. in Rev. Gén. Lait, 5 (1905), No. 3, p. 68*).—Chapters are devoted to the composition of milk, bacteriology of milk, condensed milk, milk powders, preservation of milk, casein and its industrial utilization, milk sugar, lactic acid, alcohol from milk, acetic acid from milk, and milk soap. The treatise is recommended very highly in the review to those who are interested in the industrial utilization of milk.

A note on the bacteriological examination of milk, G. Newman (*Pub. Health [London], 18 (1905), No. 3, pp. 157-159*).—This is an outline of an address in which the author discusses the bacteriological standards for milk, the kinds of bacteria and toxins present in milk, the presence of cellular elements foreign to milk, and the degree of acidity.

The following is suggested as a bacteriological standard of purity of milk for practical purposes: (1) Total acidity of not more than 24 to 25°, (2) no excess of pus or blood cells, (3) no *Bacillus coli*, *B. enteritidis sporogenes*, or *B. enteritidis* of Gaertner in 1 cc., and (4) the milk to be nonvirulent to animals, the first and last conditions being considered fixed and absolute standards and the other two relative standards suggesting further inquiry.

Uniformity in milk culture media for bacteria, B. Czaplicki (*Milchw. Zentbl., 1 (1905), No. 10, pp. 450-456*).—Varying statements made in textbooks concerning the behavior of different organisms in milk are attributed by the author as due to differences in the milk media used.

In his experiments marked differences were obtained for the same organisms when grown in diluted milk, undiluted milk, and undiluted overheated milk. The greatest development, the most marked peptonization, and the most intensive decolorization occurred in the diluted milk. The least development took place in the overheated milk. Cholera germs from numerous sources were grown in the 3 media mentioned with marked variations in the results. The diluted milk was regularly coagulated, while in only about one-half the number of cases did coagulation occur in the undiluted milk. The differences were believed to depend principally upon the amount of sugar present.

The author recommends the dilution of the milk used for culture media in the proportion of 1:1, the media being sterilized by heating for 40 minutes at 90 to 92° C. on each of three consecutive days and kept during the intervals at 35°.

VETERINARY MEDICINE.

Economic aspect of veterinary science, S. S. Cameron (*Jour. Dept. Agr. Victoria, 3 (1905), No. 7, pp. 500-506*).—In a discussion of this problem the author draws attention to the work of eradicating animal diseases in America and England, the treatment of milk fever, abortion, and the value of a well-regulated quarantine against animal diseases.

Animal plagues and quarantine laws, Profé (*Fortschr. Vet. Hyg., 3 (1905), No. 4, pp. 73-78, fig. 1*).—The author discusses the present status of a number of animal diseases, including glanders, anthrax, blackleg, rabies, pleuro-pneumonia, and swine plague, with special reference to the effectiveness of present laws in controlling these diseases. The hope is expressed that ultimately swine plague and certain other more important animal plagues may be controlled by the proper execution of these laws.

Legislation needed for the protection of Missouri live stock, D. F. Luckey (*Ann. Rpt. Mo. Bd. Agr., 37 (1904), pp. 152-156, pl. 1*).—In the author's opinion the

live-stock laws of Missouri are not fundamentally defective, but are well suited to control the more important animal plagues if conscientiously carried out. Attention is called to the desirability of cooperation between farmers and official veterinarians in the control of animal diseases.

The importance of milk and meat inspection to the public health, T. J. SULLIVAN (*Rpt. Bur. Agr., Labor and Indus. Mont., 9 (1904), pp. 266-272*).—Attention is called to the danger inherent in pathological meat and milk as agencies in the transmission of disease. The law regarding meat and milk inspection in Montana is regarded as satisfactory and as combining all necessary features for an effective regulation of traffic in meat and milk.

Hygiene of domestic animals, N. S. MAYO (*Estac. Cent. Agron. Cuba Circ. 15, pp. 4*).—Directions are given for the disinfection of stables and careful inspection of food products, water, and salt for the purpose of preserving the health of domestic animals and preventing the introduction of diseases.

Stall disinfection by means of formaldehyde and steam produced by Lingner's apparatus, PERKUHN (*Monatsh. Prakt. Tierheilk., 16 (1905), No. 7-8, pp. 289-314, figs. 5*).—The apparatus is described in detail and a report is made on disinfection experiments carried out by the author in attempts to destroy anthrax bacilli, anthrax spores, and the bacilli of hog cholera, swine plague, swine erysipelas, and glanders.

The results obtained in these experiments indicate that formaldehyde may be used successfully in disinfecting the substances and objects which lie in the open. Bacteria which may be under straw, filth, or in cracks, however, are not much influenced, since the formaldehyde penetrates rather slowly. In order that the method may be practically efficient, therefore, it is recommended that straw and filth be carefully removed from the stalls to be disinfected and that the temperature during the process of disinfection be maintained at about 10° C.

Report of the veterinary bacteriologist, A. THEILER (*Transvaal Dept. Agr. Ann. Rpt. 1904, pp. 79-248*).—The author presents a detailed account of the distribution of rinderpest serum in various parts of Transvaal, as well as on the distribution of other serums, especially that of pleuro-pneumonia, and the effectiveness of these materials.

A careful study was made of the anatomy and life history of the blood parasite of Texas fever. When susceptible animals are inoculated with blood from an animal immune to Texas fever, parasites closely resembling those of African coast fever appear in the blood, either with the second reaction or shortly afterward. African coast fever has been definitely shown to be entirely distinct from Texas fever. Numerous experiments in the transmission of African coast fever by means of ticks have demonstrated that *Rhipicephalus appendiculatus* is chiefly concerned in this process. On account of the long period during which an infection persists in a given area it is considered impossible to eradicate the disease by means of inoculation.

Notes are also given on piroplasmosis of the horse, mule, donkey, and dog. It was found possible to immunize dogs against the disease by the use of blood from a recovered dog. The author also discusses heart water in cattle, sheep, and goats. This disease appears to be transmissible from sheep and goats to cattle, and vice versa. Observations are also made on horse sickness, together with notes on the destruction of the red blood corpuscles in this disease.

Report on work of veterinary department, S. STOCKMAN (*Transvaal Dept. Agr. Ann. Rpt. 1904, pp. 37-76, pls. 2*).—The condition of live stock sanitary laws is discussed and the policy of the veterinary department is outlined as including the purpose of compelling owners of stock to report dangerous diseases, to inspect farms, quarantine infected farms, and regulate the movement of animals during outbreaks of disease.

With regard to African coast fever it is considered as established that the disease as restricted to cattle is caused by a blood parasite, is only indirectly contagious through the agency of *Rhipicephalus appendiculatus* and perhaps *R. simus*, and that the blood parasite does not pass through the egg of the tick to the second generation. The history of the invasion and spread of the disease in the Transvaal is discussed in considerable detail, and reference is made to the various systems of dipping and vaccination which have been tested. Koch's method of inoculation has proved ineffective. The destruction of diseased animals and thorough disinfection of pastures is recommended. Notes are also given on rinderpest, glanders, tuberculosis, swine plague, anthrax, sheep scab, rabies, and meat inspection.

Conference on bovine tuberculosis, S. Arloing (*Ann. Soc. Agr. Sci. et Indus. Lyon, 8. ser., 2 (1904), pp. 139-149*).—Some of the results recently obtained in experiments on tuberculosis are outlined by the author.

Particular attention is given to experiments the results of which bear upon the question of the interrelation between bovine and human tuberculosis. The author believes that the disease is mutually transmissible between man and animals and that the time has come when an organized effort should be made by all persons concerned in the control of this plague. Enough facts are now demonstrated beyond reasonable controversy to form the basis of the crusade against tuberculosis.

Anthrax, H. A. Ballou et al. (*West Indian Bul., 6 (1905), No. 2, pp. 156-170*).—The prevalence and distribution of this disease in the West Indies is discussed for the purpose of calling attention to its origin and suitable means of controlling it. It is recommended that in the control of this disease animals should be strictly inspected before slaughter in order to prevent the distribution of infection by means of meat dealers.

Preventive inoculation for redwater, J. A. Robinson (*Agr. Jour. Cape Good Hope, 27 (1905), No. 4, pp. 505-511*).—After long experience with this disease in South Africa it is recommended that for inoculation purposes the blood of animals raised on affected premises should be used and in doses of 2 to 3 cc. For this purpose, blood should not be kept for more than 12 hours before injection. Cattle should be inoculated in early spring, when the range is in good condition, and should be carefully treated during the period of immunization.

Texas fever, W. H. Dalrymple (*Louisiana Stas. Bul. 84, 2. ser., pp. 31, figs. 2*).—The bulletin contains a general popular discussion of Texas fever, including an account of the name of the disease, cause, cattle ticks and their life history, symptoms of the disease, post-mortem appearance, curative treatment, immunization, eradication of the tick particularly by the "feed-lot" method of ridding cattle and of cleaning pastures during the summer. It is believed by the author that with united action of southern States and the Federal Government the cattle tick may be exterminated.

Anaerobic bacteria as the cause of necrosis and suppuration in cattle, L. Roux (*Centbl. Bakt. [etc.], 1. Abt., Orig., 39 (1905), No. 5, pp. 531-544*).—A microscopic study was made of 27 cases of deep necrosis and abscesses in cattle with particular reference to the bacterial content of these processes and the virulence of the organisms found in them. In nearly all cases several species were associated together.

Inoculation experiments were made in pigeons, rabbits, guinea pigs, chickens, and cattle. These inoculations were either subcutaneous or intramuscular. The bacteria found in the suppurating processes are carefully described. It appears as a result of these observations that several bacteria may be considered as causing necrosis in cattle. Among the aerobic forms coli bacillus, streptococci, and *Bacterium vulgare* are mentioned, while in the class of anaerobic organisms *Bacillus necrophorus*, *B. pyogenes bovis*, and a species of spirillum seemed to be the most important. In producing necrosis best success is had when an organism of the first group is associated with one of the second group.

Pneumo-enteritis in calves, A. W. CURLEWIS (*Jour. Dept. Agr. Victoria, 3* (*1905*), *No. 2, pp. 127–129*).—This disease most frequently attacks calves between the ages of 4 weeks and 3 months, and is very fatal, the mortality being about 95 per cent. The symptoms and post-mortem appearances are briefly described. The only effective way of controlling the disease is by means of strict isolation of all affected calves and thorough disinfection.

The influence of cold on the virus of foot-and-mouth disease, E. PERRONCITO (*Fortschr. Vet. Hyg., 3* (*1905*), *No. 4, pp. 78, 79*).—The opportunity was offered of studying the effect of cold upon the virus of foot-and-mouth disease.

A sample of the virus in the saliva of diseased cattle was kept over night at a temperature of −8 to −9° C. In the morning the virus was found frozen and after being thawed out was used for inoculating two healthy calves and two sheep. None of these animals became infected, and it appears, therefore, that the subjection to −8 to −9° C. is sufficient to destroy the virulence of the virus. The author hints at the economic importance of this fact.

Spraying v. dipping, A. W. DOUGLASS and L. J. ROBERTS (*Agr. Jour. Cape Good Hope, 27* (*1905*), *Nos. 1, pp. 108–112; 2, pp. 247–249*).—This is a controversial discussion of the comparative value and effectiveness of spraying and dipping.

The first-named author argues in favor of spraying cattle with kerosene as being a method more effective and less harmful than dipping, particularly if arsenic be added to the dips. Kerosene mixed with water mechanically is claimed to be quite harmless to the skin of cattle and costs about 4 cents per head. The actual cost of dipping is not much more, but the original cost of the dipping plant is much greater than that of the necessary spraying apparatus.

Mr. Roberts maintains, on the contrary, that dipping is much more satisfactory than spraying, and has displaced the latter method on nearly all cattle ranches. It is argued that 1,000 cattle can be dipped in the time required to spray 200 head. Dipping is also claimed to be a much more effective method of destroying the ticks than spraying.

Sheep dipping (*Bd. Agr. and Fisheries* [*London*], *Leaflet 145, pp. 4*).—Notes are given on methods and materials to be used in dipping sheep for *Melophagus ovinus, Ixodes reduvius,* and *Lucilia sericata.* For this purpose a hand bath, swimming bath, or cage bath may be used.

Various preparations were used as dips, including combinations of arsenic and soda, sodium compounds of sulphur, lime and sulphur, carbolic acid, tobacco extracts, and soaps. Crude tar and tar acids appear to destroy the pests most quickly, while tobacco dips were nearly as active.

Vaccination for sheep pox and blackleg with products prepared in the Pasteur Institute of Algeria, SOULIÉ (*Bul. Agr. Algérie et Tunisie, 11* (*1905*), *No. 15, pp. 339–341*).—During the 5 years from 1900 to 1904, inclusive, 4,732,960 sheep were vaccinated against sheep pox. The mortality among this number was 1,800. In vaccination for blackleg 138,068 cattle have been treated since 1897. The total loss among this number was 150.

The indefinite preservation of the virus of sheep pox in leeches, F. J. and E. BOSC (*Compt. Rend. Soc. Biol.* [*Paris*], *58* (*1905*), *No. 7, pp. 299–301*).—Considerable difficulty has been experienced in preserving the virus of sheep pox without its undergoing rapid changes. A mixture of lymph or infected tissue in pure glycerin or diluted in water becomes rapidly attenuated.

It was found, however, that when leeches were allowed to attach themselves in the region of the pustules of sheep pox, the blood and virus thus obtained retained its virulence for long periods, even 2 years, without any noticeable attenuation. It appears that in such cases the virus may be partly digested and absorbed into the body cavity of the leeches without undergoing serious changes. It is believed that

the process may be applicable to the preservation of smallpox vaccine and vaccine for foot-and-mouth disease.

Prevention and cure of foot rot in sheep (*Jour. Bd. Agr. [London], 12 (1905), No. 6, pp. 360–364*).—In treating this disease it was recommended that copper sulphate be used at the rate of 1 lb. to a gallon of water, or a weaker solution if prevention is the only aim of the treatment. It is considered preferable to buy copper sulphate in the powdered form and under a guaranty of 98 per cent purity. Badly affected sheep should have their hoofs pared before they are driven through the copper sulphate bath.

Simple rules for judging reactions of tuberculin and mallein, O. MALM (*Norsk Vet. Tidsskr., 17 (1905), Nos. 3, pp. 49–58; 4, pp. 53–82; 5, pp. 97–100*).—The various factors which may influence tuberculin and mallein reactions are critically discussed by the author. The nature of tuberculin is defined and notes are given on the strength and specific qualities of this reagent.

In determining reactions many points have to be considered. The author believes that Koch's tuberculin is the best for use in determining the existence of tuberculosis. The most active agent in the tuberculin is a toxin of a specific nature. The conclusions are reached that cattle must be considered tuberculous if they show a temperature not above 39.5° C. before injection, and a rise of at least 1° C. after injection above the highest temperature shown before the tuberculin was administered. With calves under 6 months of age, showing a range of temperature from 39 to 39.5° C., it is considered as a sufficient ground of suspecting tuberculosis if the temperature rises above 40° C. after injection. It is recommended that tuberculin tests be not given to cattle which show a temperature above 39.5° C.

With regard to the use of mallein in the detection of glanders, it is recommended that this product be under State control and that, for injection, 0.5 cc. of the fluid preparation be used or 7 cg. of the dry material. All horses which show a rise of temperature to the extent of 1 to 2° C. within 24 hours after injection, together with general or local symptoms of irritation, are to be considered as certainly glanderous.

Report upon experiments made in the Royal Veterinary College, Dublin, on two horses obtained from a stud infected with glanders, A. E. METTAM (*Dept. Agr. and Tech. Instr. Ireland Jour., 6 (1905), No. 1, pp. 39–44*).—The two animals discussed in this article came from a stable where glanders had prevailed, and were kept under observation for the purpose of determining whether they had glanders, and also whether mallein would have a curative effect upon the disease or develop a tolerance in animals repeatedly inoculated with it.

During the course of the experiments each animal received 5 injections of mallein, the first 4 being administered at intervals of 1 week, after which 3 months were allowed to elapse before the last injection was made. Both of the animals were killed and carefully examined post-mortem. One animal was undoubtedly glanderous and responded promptly with the usual reactions after each injection. The other animal did not respond at any time, and upon the post-mortem was found to be free from glanderous lesions. A test was made on a third horse to determine the effect of killed cultures of glanders bacilli. An injection of 5 cc. of an emulsion of glanders bacilli produced no bad effects in the horse.

The author believes that the results obtained during these experiments indicate that mallein is a trustworthy diagnostic agent for glanders; that no tolerance to mallein is set up in an animal which receives repeated doses of mallein, and that infection with glanders probably occurs chiefly through the alimentary tract. The last conclusion is based on the fact that one horse did not acquire glanders, although constantly associated with the other glanderous horses.

Glanders of horses, R. R. DINWIDDIE (*Arkansas Sta. Bul. 87, pp. 61–76*).—A portion of this bulletin is occupied with a brief discussion of the nature, symptoms,

diagnosis, treatment, and prevention of glanders, with notes on the use of mallein and on officirl inspection for glanderous horses.

The Arkansas law relating to this matter provides for notification of horses affected with the disease, isolation of such animals, the prevention of traffic in affected horses or mules, the use of mallein test, and thorough disinfection of the premises after an outbreak of glanders. Brief notes are also given on the present prevalence of glanders in Arkansas. Details of inspection work carried out under this law in 1904 are furnished by J. F. Stanford.

A case of uveitis malleotica, J. DE HAAN (*Fortschr. Vet. Hyg., 3 (1905), No. 3, pp. 49, 50*).—The literature relating to the occurrence of glanders in the eyes of horses is briefly discussed in connection with a description of the symptoms as observed by the author. An examination of a case which came under observation disclosed the fact that the glanders bacilli were present in pure cultures in the exudate from the iris and choroid coat.

The action of certain oxidizing substances upon the toxin of tetanus, C. PADERI (*Arch. Farmacol. Sper. e Sci. Aff., 4 (1905), No. 1, pp. 3-23*).—The author studied the effect upon tetanus toxin of certain oxidizing substances including ozone, permanganate of potash, and sulphate of soda.

It was found that ozone, on account of its oxidizing property, greatly irritated the tissues with which it came in contact and was, therefore, somewhat injurious to the organism. It also destroyed the tetanus toxin wherever it came in contact with it. Ozone, however, apparently had no effect upon the tetanus toxin circulating in the blood, since it could not be brought in contact with it. Similarly, permanganate of potash, when brought in contact with tetanus toxin outside of the organism, quickly destroyed it, but had no effect upon the toxin circulating in the living animal organism. Sulphate of soda was even less effective.

It appears that the three oxidizing substances studied by the author are not capable of increasing the oxidizing power of the animal organism toward toxic substances in circulation in the tissues.

Studies and observations on rabies, E. BARTERELLI (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig., 39 (1905), No. 4, pp. 399-409*).—It was found during the author's study that the salivary glands of rabbits affected with rabies may sometimes become infectious, particularly if an unusually virulent virus is used.

The author studied also the relation between the appearance of Negri's corpuscles and the use of fixed virus. Experiments in the transmission of rabies to cold-blooded animals showed that the virus has no effect upon them, being excreted rapidly after injection. A study of the saliva of a man affected with rabies showed that this material was exceedingly virulent.

Rabies in Muridæ, C. FRANCA (*Compt. Rend. Soc. Biol.* [*Paris*], *58 (1905), No. 9, pp. 410, 411*).—It was found possible to produce rabies in various species of Mus and Arvicola by inoculation.

The form of the disease was usually paralytic, the symptoms being quite pronounced in all cases. A histological examination disclosed the presence of diffuse infiltration of leucocytes in the medulla oblongata and nerve ganglia, but none of the nodules described by Van Gehuchten. By means of the silver method recommended by Ramon-y-Cajal lesions are demonstrable in the nerve fibrillæ.

Treatment of rabies with radium, G. TIZZONI and A. BONGIOVANNI (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig., 39 (1905), No. 4, pp. 473-477*).—A number of laboratory animals were inoculated with fixed virus and subsequently treated with radium rays. At the time of the report it was 2 months since inoculation and the animals were considered as cured.

The curative action of radium was tested quite extensively. It was found that 10,000 radio-active units applied directly upon the eye of inoculated rabbits had the same effect whether the application was continued for 8 hours or whether 8

applications were made of one hour each. It was found also during these studies that fixed virus in vitro is rapidly decomposed by radium rays and modified into very effective vaccine toward rabies.

Fowl plague in geese, F. K. KLEINE and B. MÖLLERS (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig.*, *39* (*1905*), *No. 5*, *pp. 545-549*).—It has already been shown that the filterable virus of fowl plague may make its way into the spinal cord and brain of geese. Old geese are not very susceptible to the disease, while geese one year old or younger readily succumb within 7 days after the infection. Attention has already been called to the fact that the virus is often absent from the blood of geese dead of the disease. It is always present, however, in the brain and spinal cord, and these materials may be used for inoculation.

A number of inoculation experiments were made with such material. The presence of the organism of the disease in the blood appears to cause no great elevation of temperature until shortly before death. In some cases a subnormal temperature was noted. It appears to be possible to cultivate the virus of fowl plague until it becomes so virulent for young geese that it will not disappear from the blood. No success was had in transferring the disease to pigeons and ducks. Apparently the organism of fowl plague soon dies in unsusceptible animals. In the author's experiments it was found that the disease could be transmitted readily by placing the virus in the conjunctival sac.

Trichina and trichinosis, N. I. PETROPAVLOVSKI (*Arch. Vet. Nauk* [*St. Petersb.*], *35* (*1905*), *Nos. 8*, *pp. 714-743*; *9*, *pp. 841-879*, *figs. 7*).—The present article is in the nature of a monograph on the life history and developmental possibilities of the trichina.

In the course of the author's investigations, feeding experiments were carried on with the lard of infested swine, with infested muscles, and other tissues. A study was also made of the resisting power of trichina to the usual salting process applied to meat. Numerous experiences were also carried on in subjecting trichina to various chemical agents, such as turpentine, alcohol, chloroform, and other substances. A study was made of the reaction of trichina toward glycerin, tartaric acid, hydrochloric acid, boric acid, carbolic acid, salt, salicylates, and other substances.

Parasites in cattle and poultry in Trinidad, C. W. MEADEN (*Trinidad Bot. Dept., Bul. Misc. Inform.*, *1905*, *No. 47*, *pp. 203-208*, *fig. 1*).—Notes are given on a number of parasitic worms in cattle and chickens, especial attention being given to *Strongylus filaria*.

Nodular disease of the intestines of cattle and sheep, L. SCHEBEN (*Fortschr. Vet. Hyg.*, *3* (*1905*), *Nos. 5*, *pp. 97-104*; *6*, *pp. 121-125*, *figs. 13*).—The anatomy of *Ankylostomum radiatum* is described in detail and notes are given on the lesions which this worm produces in the intestines of cattle and sheep.

The question of the correct scientific name of this species is discussed at some length. It is argued that Ankylostomum is the common form found in intestinal nodules of cattle and sheep in Europe as well as America and that the genus Œsophagostomum is of much rarer occurrence in such lesions.

Veterinary department, E. L. MOORE (*South Dakota Sta. Rpt. 1905*, *pp. 30-32*).—In examining sheep affected with parasites, every autopsy revealed the presence of *Moniezia expansa* in the intestines and hepatic ducts.

The entire flock was treated with a solution of copper sulphate with good results. A test was made of Zenoleum in various strengths, Skabcura, and Pino Lyptol in destroying sheep ticks. Zenoleum in solutions of 1 to 2 per cent gave good results. The other remedies were effective when used in solutions of 25 per cent for Skabcura and 1 per cent for Pino Lyptol. Brief notes are also given on azoturia and glanders.

Stomach worms, A. A. BROWN (*Jour. Dept. Agr. Victoria*, *3* (*1905*), *Nos. 2*, *pp. 143-146*; *4*, *pp. 340*, *341*, *pls. 4*).—The author discusses the appearance, injurious effects, and remedies for stomach worms in the horse and sheep.

The treatment for stomach worms of the horse must be preventive, since no drug can be successfully used in expelling the parasites from the stomach. Particular attention is given to a discussion of *Spiroptera megastoma*. *Strongylus contortus* in sheep produces poorly defined symptoms. In preventing infestation with this worm sheep should be kept away from marshy pastures. Infested sheep may be treated with bisulphid of carbon in doses of 20 to 30 drops or with a mixture of ether and turpentine.

RURAL ENGINEERING.

The work of the Office of Experiment Stations in irrigation and drainage (*U. S. Dept. Agr., Office Expt. Stas. Circ. 63, pp. 30*).—This circular contains statements of A. C. True and Elwood Mead before the Committee on Irrigation of Arid Lands of the House of Representatives, regarding the work of the irrigation and drainage investigations in general, and details of the lines conducted in 1904.

Doctor Mead gives a more detailed statement of the work done during the season of 1904.

Irrigation in the western United States, R. A. VAN SANDICK (*Separate from Compt. Rend. Inst. Colon. Internat., 1905, pp. 119, figs. 28*).—This is a discussion of all phases of irrigation in the United States.

The article opens with a theoretical discussion of the economic and legal questions arising in the development of a newly occupied arid region. Then follow a description and statistical account of the arid and semiarid portions of the United States, a history of the gradual development of irrigation, a description of different kinds of irrigation constructions with the defects that have been developed in use, a classification of the different methods of obtaining water for irrigation, a description of reservoirs, earth and masonry dams, irrigation statistics, an account of the National Reclamation Act and the work which has been projected thereunder, and a consideration of the relations between State and National legislation upon irrigation.

The paper is followed by a lengthy discussion by members of the International Colonial Institute.

The East Canyon Creek Reservoir, Morgan County, Utah, W. M. BOSTAPH (*Engin. Record, 52 (1905), No. 22, pp. 594–596, pls. 3, figs. 2*).—This is a detailed description of a dam which has been described before in Government publications and periodicals.

It is a rock-filled dam with steel core protected by asphaltum concrete. Methods and cost of construction are given. The cost of dam and outlet tunnel was $127,361, or $9.93 per acre-foot of available capacity. "From a financial point of view, the enterprise has been more successful than the most sanguine of its friends anticipated. A careful estimate of crops produced by reservoir water in the year 1904 shows their value to be over $75,000, more than 58 per cent of the cost of the entire work."

Irrigation furrow plow (*Maschinen Ztg., 3 (1905), No. 21, p. 253, figs. 2*).—The plow consists of a double moldboard lister plow mounted on a four-wheeled frame. Directly behind the plow is attached an oval-shaped roller which presses the dirt into an oval-shaped ditch in the furrow made by the plow. This roller is provided with scrapers to prevent clogging. Attached to the moldboards are two blades extending backward at angles of about 45 degrees. The dirt thrown up by the plow is spread out to both sides of the ditch by means of these blades which smooth the surface next to the ditch. At the outer end of the blades are attached a few harrow teeth which spread whatever dirt reaches this point.

Underground waters of Salt River Valley, Arizona, W. T. LEE (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 136, pp. 196, pls. 23, figs. 25*).—About half of this paper consists of a careful compilation of all the information that could be obtained about every well in the valley, including the size, depth and yield, and the

formations passed through by each well. Then follow in order a discussion of the geology and physiography of the valley, of the area in which pumping underground water for use in irrigation is profitable, and of the origin of the salts in well waters and their effects on vegetation. The quantity of underground water is estimated in various ways, and the cost of pumping is discussed.

The valley fill, at least to a depth of several hundred feet, consists of river débris, wash from near-by hillsides, and chemical precipitates in more or less impervious layers, which serve in many cases to confine the underground water under some pressure. The valley fill is saturated with water more or less impregnated with various salts derived from Salt River.

The quantitative estimate of the underflow indicates a volume of flow of 148,196 to 287,760 acre-feet per year. At this rate something less than 96 pumping plants, each supplying 200 miner's in. or 5 cu. ft. per second, could be operated continuously.

"The cost of pumping in Salt River Valley varies from 5.4 to 13.8 cts. per acre-foot per foot of lift, or a cost per acre-foot of pumped water of \$2.50 to something like \$5. The volume of underflow is large, but not inexhaustible by the operation of pumps. It is capable of extended development, but there is danger that a greater draft will be made upon it than is consistent with the maintenance of the water level within practicable pumping distance."

A report on the establishment of tide-gauge work in Louisiana, G. D. HARRIS (*Geol. Survey La. Bul. 3, pp. 28, pls. 8, figs. 5*).—This is an account of the establishment of a tide-gauge station near the Gulf Coast for the purpose of determining mean tides, as the basis for establishing reliable bench-marks through southern Louisiana. The data secured will be of special value in the drainage of marsh lands along the Gulf, as it will show not only the mean-tide levels, but the height of extreme tidal waves from which the lands must be protected if they are to be used for agriculture.

It is the intention to determine by a long series of tide-gauge readings the elevation of a few seacoast bench-marks with great accuracy, and from them run a line of precise levels along the Southern Pacific Railroad and establish at intervals of, say every 5 miles, permanent bench-marks, and thereby give the true height of the same above sea level. All local lines can then be referred to one datum plane. Fairly reliable bench-marks many miles from the railroad will very soon be left by local engineers and the mapping of the region will be greatly facilitated. The results secured will be of scientific value also in the study of laws of tidal action. A detailed description of the station established at Weeks Island is given.

A study of rock decomposition under the action of water, A. S. CUSHMAN (*U. S. Dept. Agr., Office Public Roads Circ. 38, pp. 10, figs. 3*).—This is a discussion of laboratory methods of testing the decomposition of rock under the action of water, describing a new method now being used.

Manual for Iowa highway officers, A. MARSTON, C. F. CURTISS, and T. H. MACDONALD (*Ames: Iowa Highway Com., 1905, pp. 102, pls. 20, figs. 8*).—The legislature of Iowa on April 13, 1904, created the State highway commission, whose duties are to devise plans for improvement in the highways of the State, to disseminate information on the subject of good roads, and conduct demonstrations in road construction.

It is provided that the State College of Agriculture and Mechanic Arts shall act as a highway commission, and the board of trustees of the college has intrusted this work to the engineering and agricultural departments. The manual is issued by this commission. It contains a general discussion of the value of good roads, and the topography of the State with reference to road materials and construction. The State of Iowa has at present about 100,000 miles of public roads, not over 1,000 miles of which have been surfaced with either gravel or stone. Most of the roads of the State are made on section lines, but the commission recommends the abandon-

ment of this system and the locations of roads in such a way as to avoid the hills and thus reduce grades.

The necessity of drainage in order to secure a solid roadbed and to remove water from the surface of the roads is brought out, and it is recommended that road officials cooperate with drainage officials in providing for drainage. Tables are given showing the areas which can be drained with different sizes of tiles and open ditches. Specifications for drains and prices for grading are given, and various machines for road construction and maintenance are described. The King road drag, which consists of split logs or planks fastened together, is especially recommended for maintaining the surface of roads in proper condition.

Directions for the construction and maintenance of dirt, gravel, and macadam roads, and specifications for the construction of reinforced concrete culverts are given. The results of traction tests on earth and gravel roads and comparative traction tests with wide and narrow-tired wagons are included.

Road improvement in South Carolina, P. T. Brodie (*Clemson Agr. Col. Ext. Work, 1 (1905), No. 1, pp. 18–44, pls. 11*).—This is a general discussion of the subject of good roads, with some reference to South Carolina conditions.

The average cost of wagon hauling on the roads in the United States is estimated at 25 cts. per ton mile, while the cost of hauling on good roads is estimated at 10 cts. per ton mile. For improving South Carolina conditions it is recommended that grades be reduced both by cutting and filling and by going around hills rather than over them where this is necessary; and by surfacing roads with a mixture of clay and sand. A general discussion of construction of stone roads is also included.

Petrol, paraffin, or alcohol for agricultural motors, D. Albone (*Mark Lane Express, 93 (1905), No. 3868, Farm Mach. and Impl., p. III*).—This gives the results of experiments with an agricultural motor, using petrol, paraffin, and alcohol. A single motor has been made which will use any one of these. The comparative results were as follows: "With 2 gal. of petrol 3 roods of land were plowed; with 2 gal. of paraffin 2 roods, 35 poles were plowed; with 2 gal. of alcohol 2 roods, 25 poles were plowed."

Modern refrigerating machinery; its construction, methods of working, and industrial applications, H. Lorenz, trans. by T. H. Pope (*New York: J. Wiley & Sons; London: Chapman & Hall, Ltd., 1905, pp. X + 396, figs. 271*).—This is intended as a guide for engineers and owners of refrigerating plants, and contains chapters on the principles of the theory of heat, methods of cold production and energy required, the construction of compressors, apparatus for giving out and taking up heat, the erection of absorption machines, the cooling of liquids and keeping them cold, cooling air, manufacture of ice, production and application of cold at very low temperatures, and determination of the yield of cooling machines. There are chapters on American practice in refrigeration, insulation, and auditorium and other cooling, by H. M. Haven and F. W. Dean.

RURAL ECONOMICS.

Contributions to the economics of agriculture, F. Aereboe (*Mitt. Landw. Inst. Breslau, 3 (1905), No. 3, pp. IV+311–457*).—This monograph treats of the general principles which underlie the organization of the farm in such a manner as will enable the farmer to secure, one year with another, the best possible results.

The factors of production—land, labor, and capital—are discussed from the standpoint of the proper degree of intensity of culture. The various branches of agricultural production, such as grain production, fodder production, and the various lines of live-stock production, are discussed from the standpoints of their relations to each other and of the external conditions, such as the character of the soil and the local market prices of the products, which determine the relative importance to be given to each of these lines of production.

Agricultural explorations in Algeria, T. H. KEARNEY and T. H. MEANS (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 80, pp. 98, pls. 4*).—This bulletin describes the climate, topography, soil, agricultural products, and general economic conditions of Algeria.

The climate of Algeria is comparable to that of California. The vine is the greatest single source of wealth. The average annual value of the products of the vineyards is estimated at $5,000,000. The principal orchard fruits are the olive, citrus fruits, figs, and dates. Of these, the olive stands first in commercial importance. Near the coast are many market gardens, from which shipments are made to the European markets in the winter and early spring.

The principal field crops are wheat and barley, which occupy about 7,000,000 acres annually, and which supply a large export trade. Indian corn and sorghum are grown by the natives. "The only valuable 'industrial' crops are tobacco and certain plants used in the manufacture of perfumery."

Studies upon the development of the demand for agricultural labor in East Prussia during the nineteenth century, F. WEGENER (*Landw. Jahrb., 34 (1905), No. 3-4, pp. 311-488*).—This paper shows that there was a great increase in the production of all classes of farm products in East Prussia during the nineteenth century.

It is emphasized that this increased production has resulted principally from an increase in the intensity of culture. The higher degree of intensity of culture has necessarily made an increased demand for labor. The increase in the number of laborers has not kept pace. There have been two results: (1) Wages have risen and the condition of the agricultural laborers has been materially improved. (2) Labor-saving machinery has been introduced.

"The introduction of machinery in agriculture has not, as in the manufacturing industries, resulted in the lowering of the level of intelligence among the working classes. On the contrary, it has resulted in increased intelligence and skill. . . . Machinery has not resulted, as in the manufacturing industries, in a decrease but in an increase in wages."

Agricultural laborers in the district of Melun, H. HITIER (*Jour. Agr. Prat., n. ser., 10 (1905), No. 41, pp. 458, 459*).—This article is a brief review of a comprehensive report on the same subject by M. Brandin.

In recent years the native agricultural laborers of northern France, notably in the regions of sugar-beet production, have desired the restriction and even the prohibition of the immigration of foreign agricultural laborers. The native laborers believe that such restriction will result in an important increase in their wages. The investigations of M. Brandin lead to the conclusion, however, that such restrictions will depress rather than raise wages.

There are two systems of crop rotation from which the farmer of this district may choose: First, wheat, oats, and sugar beets; and, second, wheat, oats, and grass crops sown with the oats. It is calculated that the first system makes a demand for five laborers on the same area that the second system makes a demand for two; but if the native laborers must be depended upon, there will be no more than three laborers where five will be needed for the system including the sugar beets. Hence the restrictions on the influx of foreign laborers will make it necessary for the farmers to resort to the more extensive of these two systems of culture. This will make a demand for but two laborers where there are three native laborers competing for the positions.

Thus it is that restrictions on the immigration of laborers instead of resulting in a rise in wages may bring about a retrograde movement in agriculture and depress wages.

Laborers' holdings in Denmark (*Dept. Agr. and Tech. Instr. Ireland Jour., 5 (1905), No. 4, pp. 701-709*).—This article describes recent legislation in Denmark which provides for State aid to agricultural laborers in securing small holdings.

Agriculturists and breeders, L. LÉOUZON (*Agronomes et Eleveurs. Paris: J. B. Baillière & Sons, 1905, pp. 360, pls. 20*).—This book contains a sketch of the lives and the contributions to scientific agriculture of twenty-two eminent agriculturists, namely: Robert Bakewell, founder of the breeder's art; Charles and Robert Colling, of the County of Durham, Eng., who developed the breed of Durham cattle; Arthur Young, an agricultural writer and first secretary of the English Board of Agriculture; Sir John Sinclair, first president of the English Board of Agriculture; Coke, of Holkham, a champion of large farms, intensive culture, and scientific methods in English agriculture; Jonas Webb, the improver of the Southdown breed of sheep; Sir John Bennett Lawes, founder of the Rothamsted Experiment Station; Albrecht Thaer, agriculturist, breeder, author, and educator; Oliver de Serres, a French agricultural writer; Tessier, who introduced merino sheep into France; Mathieu de Dombasle, founder of the School of Agriculture at Roville; Auguste Bella, agricultural writer and educator; C. A. Yvart, Belgian veterinarian and breeder; A. E. Pierre, Comte de Gasparin, noted for his work on contagious diseases of animals; Emile Baudement, a writer and educator on the subject of cattle breeding; Edward Malingié, sheep breeder, writer, and educator; J. B. Boussingault, agricultural chemist and physicist; J. A. Barral, agricultural journalist; and Edouard Lecouteux, agricultural writer and educator.

Trade with noncontiguous possessions in farm and forest products, 1902–1904 (*U. S. Dept. Agr., Bur. Statis. Bul. 37, pp. 49*).—This report contains statistics of the trade in farm and forest products between the United States and her noncontiguous possessions, viz, Porto Rico, Hawaii, Alaska, Philippine Islands, Tutuila, Guam, and Midway Islands.

Farm products represent 36.2 per cent of the value of the shipments from the United States to the noncontiguous possessions, and 79.6 per cent of the shipments to the United States from these possessions. "In 1904 sugar formed 75 per cent of the total shipments of domestic merchandise from Porto Rico to the United States and 97 per cent of the corresponding shipments from Hawaii. Manila formed 92 per cent of all domestic merchandise imported from the Philippines into the United States in 1904."

Imports of farm and forest products, 1902–1904 (*U. S. Dept. Agr., Bur. Statis. Bul. 35, pp. 82*).—This bulletin presents a statistical review of the sources, the character, and the value of imports of farm and forest products into the United States.

The imports of farm products in 1904 were valued at $461,434,851, and represented 46.6 per cent of the total imports. The imports of forest products in the same year were valued at $79,619,296. Over 62 per cent of the imports of farm products came from eight countries, viz, Cuba, Brazil, United Kingdom, Japan, China, Mexico, Italy, and France. Sugar is the principal farm product imported from Cuba, coffee from Brazil, wool from the United Kingdom, and raw silk from Japan.

The leading imports of farm and forest products in the order of their importance in 1904 are: Sugar, $72,933,951; coffee, $69,551,799; hides and skins other than furs, $52,006,070; vegetable fiber, $46,355,795; silk, $46,100,500; India rubber, $40,444,250; wool, $24,813,591; fruits, $18,964,688; tea, $18,229,310; tobacco, $16,939,487; lumber, $12,026,857.

Exports of farm and forest products, 1902–1904 (*U. S. Dept. Agr., Bur. Statis. Bul. 36, pp. 108*).—This report shows the quantities and the values of the imports and the exports of the various classes of farm and forest products to and from the Undite States.

The value of farm products exported during the year ended June 30, 1904, was $872,000,000, which is greater than for any previous year, with the exception of the 2 years 1901 and 1903. But while the value of exports of farm products has greatly increased during the past 15 years, this increase has not kept pace with that of other lines of production. Farm products represented only about 60 per cent of

the total value of our domestic exports in 1904, whereas the percentage was about 68 on the average during the 15 years from 1890 to 1904.

The figures show that while the exports of other kinds of farm products remained stationary or increased, the exports of grain and grain products decreased from $221,-459,086 in 1903 to $149,366,054 in 1904, which is less than in any other year since 1891. The exports of forest products more than doubled during the decade ending June 30, 1903. The exports for 1904 were valued at $70,000,000, which was an increase of about $12,000,000 over any previous year.

The United Kingdom, by far the most important purchaser of our farm and forest products, takes about 47 per cent of the farm products and about 30 per cent of the forest products.

Crop export movement and port facilities on the Atlantic and Gulf Coasts, F. ANDREWS (*U. S. Dept. Agr., Bur. Statis. Bul. 38, pp. 80*).—This report is a study of the commercial movement of cotton, corn, and wheat in the United States.

A discussion is given of the regions where these materials of commerce are produced in the United States, of the primary markets or trade centers in the interior where they are concentrated, of the movements from the primary markets to the various Atlantic and Gulf ports, and of the facilities for handling these products at these ports. It is shown that the proportion of the export of cotton and wheat exported from the Gulf ports has gradually increased during the last twenty years, whereas the proportion exported from the Atlantic ports has declined.

From 1884–1888, 44 per cent of the cotton exported was shipped from the Gulf ports and 55 per cent from the Atlantic ports. During the same time 2 per cent of the wheat exported was shipped from the Gulf ports and 59 per cent from the Atlantic ports. In 1904, 65 per cent of the cotton and 55 per cent of the wheat exported were shipped from the Gulf ports and only 33 per cent of the cotton and 20 per cent of the wheat exported were shipped from the Atlantic ports.

Agricultural statistics of Ireland for 1904 (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1905, pp. XXXVIII + 165, dgms. 2*).—This report contains statistics on the size of farms, the areas devoted to the different lines of production, the number of live stock on farms, and the number of live stock exported.

The statistics show Ireland to be primarily a grazing country. About 75 per cent of the total area, or about 15,000,000 acres, is devoted to agricultural purposes. Of this only 15.6 per cent is devoted to crops other than hay, 14.9 per cent to hay, and 69.5 per cent to pasture. The acreage devoted to crops has been steadily decreasing for many years, while the areas devoted to hay and pasture have been increasing. The oat crop is by far the most important of the grains grown in Ireland, and cattle are the most important live stock. Cattle, horses, sheep, and swine are exported to Great Britain in relatively large numbers.

While there are a few large farms in Ireland, the agricultural holdings are, as a rule, small. The average size of holdings larger than one acre is about 29 acres, which is less than half the size of those of England.

Report of the government statistician on agricultural and pastoral statistics for 1904 (*Rpt. Govt. Statis. on Agr. and Pastoral Statis. Queensland, 1904, pp. 57*).—This report contains statistics on the sizes of farms, flocks, and herds; on irrigation; on the production of meat, dairy products, poultry, honey, wool, cotton, cereals, coffee, fruits, sugar, tobacco, and wine; and on the agricultural exports and imports of Queensland.

AGRICULTURAL EDUCATION.

First principles of agriculture for the primary schools of Bolivia (*Primeras nociones de agricultura para les escuelas primarias de Bolivia. La Paz: Min. Colonies and Agr., 1905, pp. 52*).—This is an elementary text-book of agriculture issued by the Ministry of Colonies and Agriculture for the primary schools of Bolivia.

It contains chapters on the nature of soils, preparation of soils, tillage experiments, influence of climate, irrigation and fertilizers, seed time and harvest, cereals, legumes, root crops, forage plants, textile plants, sugar plants, dye plants, oil-producing and aromatic plants, arboriculture, zootechny and breeding, and agricultural machinery. The last two subjects are treated with great brevity, occupying only 2½ pages of the pamphlet.

Horticultural education, F. A. WAUGH (*Trans. Peninsula Hort. Soc.* [*Del.*], *18* (*1905*), *pp. 123–130*).—A paper showing recent progress in methods of horticultural instruction and bringing out the educational factor in horticulture.

Agriculture in the schools, F. H. HALL (*School News and Pract. Ed.*, *19* (*1905*), *No. 3, pp. 118, 119*).—A discussion of some of the things Illinois has done to promote the teaching of agriculture in the public schools.

Nature study, F. OVERTON and MARY E. HILL (*New York, Cincinnati, and Chicago: American Book Co., 1905, pp. 142, figs. 66*).—The design of this book is to furnish a year's work in nature study for pupils from 8 to 11 years of age upon subjects connected with everyday life and easily procured, even in the larger cities.

The subjects are arranged in the order of the seasons, and the lessons are intended to throw light on the unfamiliar side of familiar things as a basis for future scientific studies. Under each subject the work of one lesson is outlined quite fully, then suggestions are given for supplementary work intended to cover several lessons. The book thus embodies two valuable features, (1) concrete and detailed directions for a certain amount of work in connection with each subject considered, and (2) questions and suggestions which are presented in such a way as to stimulate continued observation and study on the part of both teacher and pupil.

Mrs. Anna B. Comstock, of the Bureau of Nature Study, Cornell University, has written an introduction to the work.

Nature teaching, F. WATTS and W. G. FREEMAN (*New York: E. P. Dutton & Co., 1904, pp. 193, figs. 20*).—This is a revision of an earlier work, prepared by Francis Watts for use in the West Indies, to adapt it to conditions existing in the British Islands.

The book is intended for use in schools and is quite strongly agricultural in its bearing, as the following list of chapter subjects indicates: The seed, the root, the stem, the leaf, the soil, plant food and manures, flowers and fruits, weeds, and animal pests of plants. Numerous experiments which will demand some originality on the part of both teacher and pupil are suggested. A glossary is given and appendixes which contain suggestions for courses of study and a list of apparatus and materials required for the work outlined in the book.

Nature study, W. N. HUTT (*Md. Agr. Col. Bul.*, *1* (*1905*), *No. 3, pp. 20, figs. 10*).—Nature study is defined and its purposes in the school are discussed. The writer also tells how to teach nature study, how to prepare material, and gives suggestions for nature study work at different seasons of the year.

A nature study of Maryland plants, F. H. BLODGETT (*Md. Agr. Col. Bul.*, *2* (*1905*), *No. 1, pp. 26, pls. 14*).—Numerous common plants of Maryland are taken up in the order of blossoming and their habitat and some peculiarities are described. The bulletin is adapted to the use of the teacher and the numerous questions interspersed through the text are intended to aid in an intelligent study of the incidents in the lives of plants.

Report of the committee on school gardens and native plants for the year 1904, H. S. ADAMS (*Trans. Mass. Hort. Soc., 1905, II, pp. 295–317, pls. 7*).—This report includes an account of school gardens, children's home gardens, children's herbariums, and collections of native plants, all of which are encouraged by the Massachusetts Horticultural Society by means of prizes and gratuities, amounting in 1904 to $225. Detailed reports are given of school gardens in Framingham, Groton, and Lynn, Mass.

School gardens for California schools, B. M. DAVIS (*Cal. State Normal School, Chico, Bul. 1, pp. 79, figs. 11, chart 1*).—This is a manual for teachers based on experiments in school garden work at the Los Angeles and Chico State normal schools.

The author deals briefly with the history and development of school gardens and their educational value; devotes a chapter to the plant and its relations, including soils, fertilizers, temperature, and plant enemies, with an annotated list of some of the most common and important insects of California; another chapter to plant propagation, in which is included a plant calendar containing condensed information concerning quite a variety of vegetables, flowers, and climbing plants; a third chapter to instruction, including practical work and correlative subjects; a brief description of school gardens at Los Angeles and Chico; an abridged list of useful books and bulletins for a school library; references to literature on insects mentioned in the text, and a bibliography of 218 entries on school gardens, nature study, elementary agriculture, and horticulture. An appendix contains "some exercises for experimental study of soils and other factors of plant growth."

A new kind of garden school, MARY L. BUTLER (*Gard. Mag. [New York], 2 (1905), No. 3, pp. 132–134, figs. 11*).—A description is given of the garden school which has been conducted under private control during the past 3 years at Yonkers, N. Y. An itemized statement is made of the cost of conducting the school during the summer of 1904.

The present status and future development of domestic science courses in the high school, ELLEN H. RICHARDS (*Fourth Yearbook Nat. Soc. Sci. Study Ed., 1905, pt. 2, pp. 39–52*).—In addition to a discussion of the nature and extent of domestic science teaching suitable for high schools, the author gives an outline for a 4-year high school course in domestic science "based upon at least 3 years' work in the grades in which evident facts and manual skill have been acquired."

This course provides for instruction 2 to 4 hours weekly during the first and second years, 2 to 6 hours weekly during the third year, and 4 to 6 hours weekly the fourth year on the following subjects: Hygiene, physiology, drawing, textiles, physics, economic botany, general chemistry, preparation of foods, foods for the sick, balanced ration, biology, sanitation and civics, economics, and drawing and design as applied to house plans and decoration, with some experiments and library work.

Housekeeping schools for farmers' daughters, J. I. BRITTAIN (*Mo. Consular Rpts. [U. S.], 1905, No. 296, p. 133*).—Traveling schools for the instruction of girls in nutrition and related branches of home economics are in operation in some of the German provinces, and it is proposed, according to the author, to establish such schools in Alsace-Lorraine.

MISCELLANEOUS.

Eighteenth Annual Report of Arkansas Station, 1905 (*Arkansas Sta. Rpt. 1905, pp. VIII + 99*).—This contains the organization list; a brief statement of the director; a financial statement for the fiscal year ended June 30, 1905; and reprints of Bulletins 83–87 of the station, on the following subjects: Broom corn suggestions (E. S. R., 16, p. 560); peanuts (E. S. R., 16, p. 560); cotton food products in hog feeding (E. S. R., 17, p. 280); asparagus and salt (E. S. R., 17, p. 251); asparagus-growing in Arkansas (E. S. R., 17, p. 251); rhubarb in Arkansas (E. S. R., 17, p. 253); fertilizers registered for sale in Arkansas during 1905 (E. S. R., 17, p. 229); and glanders of horses (E. S. R., 17, p. 594).

Twelfth Annual Report of Minnesota Station, 1904 (*Minnesota Sta. Rpt. 1904, pp. XIII + 281*).—This contains the organization list; subjects of bulletins issued during the year; a report of the director on the work of the station and experiment farms during the year; and reprints of Bulletins 83–86 of the station on the following subjects: Apples and apple growing in Minnesota (E. S. R., 15, p. 473); insects,

injurious, in 1903 (E. S. R., 15, p. 1089); glutenous and starchy wheats (E. S. R., 15, p. 1095), composition and bread-making value of flour produced by the roller process of milling (E. S. R., 15, p. 1095), the relative protein content of wheat and flour (E. S. R., 15, p. 1096), composition of an ancient Egyptian wheat (E. S. R., 15, p. 1073), influence of storage and bleaching upon flours (E. S. R., 15, p. 1097), the relative food value of graham, entire-wheat, and straight-grade flours (E. S. R., 15, p. 1098); the food value of sugar (E. S. R., 15, p. 1098), the digestive action of milk (E. S. R., 15, p. 1099).

Annual Report of South Dakota Station, 1905 (*South Dakota Sta. Rpt. 1905, pp. 11-32*).—This is a report of the director of the station including a financial statement for the fiscal year ended June 30, 1905, and supplemented by departmental reports, some of which are noted elsewhere.

Accessions to the Department Library, April-September, 1905 (*U. S. Dept. Agr., Library Buls. 56, pp. 76; 57, pp. 47*).

NOTES.

Arizona Station.—F. W. Wilson, of the Kansas Agricultural College, has been appointed in charge of the department of animal husbandry, which position has been vacant for some time. His duties will include the organization and conduct of farmers' institutes for about three months each year. George E. P. Smith has succeeded S. M. Woodward, now of this Department, as irrigation engineer. About $10,000 was expended for improvements during the past calendar year. These included a residence and pumping plant at the Tempe cooperative date orchard, a residence and barn at the station farm in Phoenix, and a cottage on the new date orchard at Yuma.

Colorado Station.—Special field investigations in fruit growing will be made on the western slope of the State, with headquarters at Grand Junction. Two field men, one an expert horticulturist and the other an entomologist, will be in charge of this work. The orchardists in that section have experienced considerable trouble, and it is thought that the various problems can be best studied on the grounds. The work is to be carried on at the request of the fruit growers of western Colorado, who have raised $1,500 for the purpose. Drainage and seepage investigations will also be carried on in the same locality in conjunction with the other work. A. H. Danielson, who has been with the station for five years as assistant agriculturist, resigned January 1 to devote his time to private interests.

Idaho Station.—J. Shirley Jones, a graduate of the University of California, has accepted the position of chemist to the station, vice J. S. Burd, and entered upon his work January 1.

Louisiana Stations.—J. A. Verret has resigned to accept a position as manager of a sugar house in the Hawaiian Islands.

Massachusetts College and Station.—Hon. Carroll D. Wright, president of Clark College, has been appointed by the Governor a member of the board of trustees of the college, to succeed William R. Sessions, resigned. At a special meeting of the board of control W. P. Brooks was elected director of the station, the office being separated from that of president. The new horticultural building is nearly completed and is being occupied. Dr. C. A. Goessmann, formerly director of the State Station, has been elected honorary director of the station.

Michigan College and Station.—T. A. Farrand, in charge of the South Haven substation, has resigned to engage in business. A. G. Craig, instructor in horticulture, has accepted a similar position at the Washington College.

Minnesota University and Station.—The foundation for the new main building has been completed. It is 250 ft. long by 73 ft. wide, with a wing 73 ft. by 79 ft. on the east side. Provision was made for the erection of this building by the State legislature three years ago. When completed it will contain the offices of the dean, secretary, and principal of the school of agriculture; offices and laboratories for the departments of agriculture and entomology, and a number of class rooms for the general work of the school of agriculture. There will also be a chapel and assembly hall, and the library will occupy a prominent place on the first floor. The building is located on a tract of land adjacent to the main avenue of the campus, which was purchased mainly for this purpose. When completed it will greatly facilitate the work of both the college and station.

In order to promote the use of better seeds throughout the State, the school of agriculture has undertaken an educational seed-growing contest. Wheat, corn, and oats will be grown in competition for prizes, and the best seeds obtained disseminated for seed purposes. The movement is financed by the Minneapolis Chamber of Commerce, and it is the aim to give the contest as much of an educational feature as possible.

The farmers' clubs of the State, consisting of graduates and former students of the school of agriculture, have been holding a series of agricultural meetings recently. In many counties these clubs have been formed and are affiliated with a central organization. The programmes of the different meetings are arranged to meet the agricultural conditions of the different localities.

Nebraska University and Station.—Roscoe H. Shaw, for several years past assistant in the chemical department of the Kansas Station, has been appointed associate chemist in the station and assistant professor of agricultural chemistry in the university, vice Alvin Keyser, who has been transferred to assistant in soil investigations in the agricultural department of the university and station.

Oklahoma College and Station.—Four hundred and three students were enrolled in the week's course in stock judging and seed selection, given at the college January 9–15. H. J. Webber and W. J. Spillman, of this Department, gave lectures in connection with the course. The corner stone of Morrill Hall, the new agricultural building, was laid January 15, Hon. Rudolph Kleiner, president of the Oklahoma board of agriculture, delivering the address.

Pennsylvania College and Station.—At a recent meeting of the board of trustees it was decided to set off the respiration-calorimeter and other feeding work as a separate department, to be known as the Institute of Animal Nutrition, and to be in charge of a director. The dean of the college of agriculture and director of the experiment station will be combined in one officer, to be selected later. The Institute of Animal Nutrition will be a department of the college, affiliated with the experiment station. Dr. H. P. Armsby has been appointed director of the new institute, and upon the selection of a dean and director will be relieved of administrative work connected with the experiment station.

South Carolina Station.—At a recent meeting of the governing board, F. H. H. Calhoun of the college was elected geologist of the station.

Virginia Station.—It is noted from press reports that a bill has been introduced into the State legislature providing an annual appropriation of $10,000 for the experiment station, and regulating the expenditure of the appropriation.

West Virginia Station.—Frank F. Grout, assistant chemist, has resigned to take up work at the University of Illinois in connection with the geological survey and the engineering experiment station.

Wyoming University and Station.—The third annual short course at the university closed on January 13. The attendance was good, and the block demonstrations brought out some interesting data in regard to feeding lambs on various rations of grain and native hay. The demonstration was conducted by D. A. Gaumnitz, of the Minnesota College of Agriculture.

The station has secured a new Polled Hereford bull to take the place of Polled Admiral, head of the herd, which died a short time ago. Some new breeding experiments with hogs have been inaugurated also.

Digestion experiments which have been conducted show a high digestibility for the alfalfa raised at the high altitude of the station (7,200 ft.). This fact in connection with the protein content, which is higher than that of the average alfalfa in other places, gives the hay a nutritive ratio of 1:3.2. With the shortness of season and dryness of climate, protein seems to increase in all crops.

The Graduate School of Agriculture.—The plan for the Graduate School of Agriculture, to be held under the auspices of the Association of American Agricultural Colleges and Experiment Stations, at the University of Illinois, July 2–28, 1906, has been approved by the committee on graduate study, and arrangements are now being made to carry it out. The Director of this Office will act as dean, and the faculty will consist of specialists drawn from the agricultural colleges and experiment stations and this Department.

Courses will be given in agronomy (including the physics, chemistry, and bacteriology of soils and field-crop production), horticulture (together with plant physiology and pathology relating thereto), breeding of plants and animals, and zootechny (with special reference to meat production). Every effort will be made in the choice of men and subjects to have the strongest possible presentation and discussion of the results recently obtained by research and capable of reduction to pedagogical form. Emphasis will be laid on the local facilities and environment to bring out the numerous advantages which the University of Illinois has to offer to such a school.

During five days in each week the forenoons will be occupied with lectures and the afternoons will be given to seminars and demonstration exercises, in connection with which there will be much opportunity for the consideration of the questions which naturally are uppermost in the minds of advanced students. On Saturdays conferences will be held on general topics in agricultural education, and excursions are planned to the stock yards and packing houses in Chicago, and to typical Illinois farms.

Public opening exercises will be held during an evening of the first week of the session, at which it is expected that addresses will be given by the Secretary of Agriculture, the chairman of the committee on graduate study, the president of the University of Illinois, and the dean of the graduate school. Other evening exercises, largely of a social character, will be provided for.

The school will be open to graduates of colleges and other persons recommended by college faculties as qualified to profit by advanced instruction in agriculture. All correspondence relating to membership in the school should be addressed to Prof. Eugene Davenport, Registrar, College of Agriculture, University of Illinois, Urbana, Illinois.

Conference on Irrigation Work.—A conference of 14 men connected with the irrigation and drainage investigations of this Office was held in Washington beginning January 16. The field men in attendance were all connected with the investigations of irrigation as related to dry farming, a new work for this Office and one which is assuming so much importance that it seemed necessary to have a special conference regarding the methods to be followed. All phases of the irrigation work were considered, however, with results of so much value that it is hoped to make these meetings a feature of each year's work hereafter, having as large a part of the force present as possible.

The various subjects considered were assigned to committees, which presented reports upon matters relating to the conduct of the investigations. Copies of these reports and an account of the meeting will be sent to all persons connected with the irrigation work, so that they will in a large measure share in the benefits of the conference. One important point decided upon was the publication of a series of manuals of popular, practical character upon the following subjects: (1) Manual of Irrigation Practice (Revision of Office Expt. Stas. Bul. 145); (2) A Manual of Canal Management; (3) A Manual of Water Measurement and Distribution in Irrigation; (4) Methods and Cost of Pumping Water for Irrigation; (5) The Construction of Farmers' Reservoirs; (6) The Irrigation of Sugar Beets; (7) The Irrigation and Drainage of Rice Fields (Texas and Louisiana); (8) Some Special Forms of Organizing Irrigation Enterprises; (9) The Terracing and Drainage of Hillsides; (10) The

Drainage of the Atlantic Coast Rice Fields; (11) Practical Information for the Settler in Irrigated Districts.

Order Relative to Government Printing.— The President has issued an order relative to the printing of the Government Departments, the character of material to be included in annual reports, etc. This order calls for the appointment by the head of each Executive Department of an advisory committee on the subject of printing and publications, in accordance with which Assistant Secretary W. M. Hays, Prof. Willis L. Moore, of the Weather Bureau, and Mr. Geo. Wm. Hill, chief of the Division of Publications, have been selected for this Department. "It shall be the duty of such committee, under direction of the head of the Department, to see that unnecessary matter is excluded from reports and publications; to see that copy is carefully edited before rather than after going to the printing office; to do away with the publication of unnecessary tables, and to require that statistical matter be published in condensed and intelligible form; to supervise the preparation of blank forms; to require the frequent revision of mailing lists; to prevent duplication of printing by different Bureaus; to exclude unnecessary illustrations from Department documents, and to prevent the printing of the maximum edition allowed by law, when a smaller edition will suffice; to recommend to the head of the Department, for inclusion in the recommendations contained in his annual reports, needed changes in the statutes governing Department publications."

The President has also directed that annual reports shall be confined to concise accounts of work done and expenditures incurred during the period covered, with recommendations relating to the future, and shall not include contributions to knowledge in the form of scientific treatises, material compiled by persons not connected with the reporting office, biographical and eulogistic matter, or detailed descriptions and lists of methods, processes, etc. The illustrations are to be much restricted, as are also tabular matter and texts of laws and court decisions.

Bills Before Congress.—The following bills of agricultural interest have recently been introduced: To require the Secretary of Agriculture to make monthly reports as to the long-staple cotton, pineapple, and orange crops; authorizing the Secretary of Agriculture to make experiments to eradicate splenetic or southern fever ticks, and appropriating $25,000 for the purpose; authorizing the Secretary of Agriculture to make experiments with a view to eradicating Texas fever, and appropriating $100,000 for the purpose; granting to the State of Minnesota certain lands to be set aside for experimental work in forestry; to prevent the adulteration of blue grass, orchard grass, clover, and alfalfa seed, and providing for inspection by the Bureau of Plant Industry; to enable the Secretary of Agriculture to examine and report upon the nature, quality, and condition of seed and grain, and appropriating $30,000; to further promote the dairy industry of the United States, appropriating $20,000 to be expended under the direction of this Department; authorizing the Secretary of Agriculture to make experiments and investigations in utilizing limited water supplies in connection with farming in the semiarid regions, and appropriating $30,000 for the purpose; and a bill providing for the segregation of $1,000,000 from the Reclamation Fund, to be used for constructing a system of land drainage in six counties of North Dakota, under the supervision of the Secretary of Agriculture, benefits to be assessed against the lands drained and to be returned to the fund.

The Adams bill for the increased endowment of the experiment stations was reported January 15, and at that time Mr. Adams submitted a statement briefly setting forth in admirable terms the present position of agricultural experimentation in relation to the development of agriculture, the great value of the experiment stations, and the need of further appropriation, which has grown out of their work.

Agricultural Experimentation in Russian Poland.—A recent issue of *Die landwirtschaftlichen Versuchs-Stationen* (Vol. 63, No. 1-2) contains a historical account of agri-

cultural experimentation in Russian Poland. From this it is learned that in 1876 a chemical laboratory was established in the Warsaw Museum of Industry and Agriculture, and in 1880 a botanical section with a seed-testing station. In 1886 an agricultural experiment station was founded in Sobieszyn through the generosity of Count K. Kicki, who gave his whole fortune to the promotion of agriculture. The laboratories were enlarged in 1892, the experimental fields rearranged, and a plant-breeding garden laid out.

This remained the only experiment station until a group of agriculturists in the government of Plock established the agricultural experiment station of Chojnowo, which was moved to Hruszczewo in 1904. In the same year representatives of the sugar industry established a station in Grodzisk, which four years later was moved to Jezowka. An experiment station for the brewing industry was started in Warsaw in 1898. The following year the agriculturists of the government of Warsaw located an experiment station at Kutno, to which an experimental field at Lenczyca was added in 1902. An experimental field was also established under private auspices at Chmilnik in 1902. Through the efforts of the Agricultural Society of Warsaw the agricultural laboratory was opened in Warsaw in 1901, and in 1903 a station for the testing of agricultural machinery and apparatus, and a station for plant protection were established at the same place. An experimental field was also started at Piastow in the same year.

The experiment stations and fields of Russian Poland, therefore, owe their origin and support entirely to private enterprise, none of them receiving any aid from the government. The directors of the stations formed a society in 1902 and adopted uniform methods of analysis for soils, fertilizers, and seeds, which have been accepted by the local fertilizer manufacturers and seed dealers.

Experiment Stations in France.—The Minister of Agriculture in a recent report to the President of the Republic calls attention to the inadequacy of the French system of agricultural research as compared with similar institutions in Germany, Austria, and the United States. The Minister has therefore appointed a committee on the organization and improvement of agricultural investigation in agricultural experiment stations and laboratories. This committee is composed of 65 members, including officers of the Department of Agriculture, directors of agricultural schools, senators, deputies, members of the National Agricultural Institute, and of the National Agricultural Society, besides other men of note in the agricultural world.

An entomological station has recently been established in connection with the zoological laboratory of the Faculty of Sciences at Rennes, under the directorship of F. Guitel.

A New Station for Testing Agricultural Machinery.—The commission for testing machinery connected with the Chamber of Agriculture of the Province of Hanover, at its meeting May 12, 1905, resolved to enlarge its functions by the establishment of a machine-testing station, to be in charge of Prof. Alwin Nachtweh.

Prize for Work on the Value of Calcium Phosphate in Feeding.—The Mecklenburg Patriotic Society has offered a prize of 1,500 marks (about $360) for a treatise upon the question, Is the Feeding of Calcium Phosphate Advantageous? Experiments, including digestion trials, are to be made with ruminants, pigs, and horses, and the reputed effect of this material on the strength of the bones is to be studied. The question as to whether the same results can not be secured with calcium carbonate is also to receive attention. The competition for this prize closes September 15, 1908.

American Association for the Advancement of Science.—This association held its fifty-fifth annual meeting at New Orleans, Louisiana, during the week beginning December 29, 1905. As usual, a number of affiliated societies met with the association. The attendance was smaller than usual, there being but about 300 delegates and visitors present. A large number of papers and addresses of popular and scientific interest

were presented, many of them dealing with different phases of agriculture. The more important of these are noted below.

The address of the retiring president, Dr. W. G. Farlow, was upon the subject of The Popular Conception of the Scientific Man at the Present Day. Dr. Elwood Mead, of this Office, gave a public address on the subject of irrigation, illustrating his address with an excellent collection of stereopticon views of Egyptian, Italian, and American irrigation. It was considered that irrigation in Egypt represents primitive irrigation, the success of which is not the result of superior methods but of the marvelous fecundity of nature, while that of Italy, on the other hand, represents the highest achievement of engineering skill in the utilization of resources in land and water and the perfection of laws and customs governing the use of water. The greater part of the address was devoted to the development and present status of irrigation in the United States.

The association adopted resolutions to Congress looking toward the preservation of Niagara Falls as a National park and the establishment of the Southern Appalachian Forest Reserve. Dr. W. H. Welch, of Johns Hopkins University, was elected president of the association. It was decided to hold the next summer meeting at Ithaca, N. Y., and the winter meeting in New York City.

American Chemical Society and Section C.—F. P. Venable, president of the American Chemical Society, in his address on Chemical Research in the United States, reviewed the progress of chemical research in this country and plead for more original work.

L. P. Kinnicutt, in an address on The Sanitary Value of Water Analysis, discussed the value of chemical and bacteriological examinations in detecting pollution of surface, ground, and artesian waters. It was considered that the bacteriological examination, while giving information as regards recent and continuous pollution, gives no information as to the past history of a water and in this respect differs from a sanitary chemical analysis. Hence an opinion concerning the wholesomeness of a water should be based upon all the information obtainable about it.

H. W. Wiley discussed Some Important Problems in Agricultural Chemistry, touching among other things upon problems relating to plant food, cider investigations, preservation of food products, and nutrition investigations.

C. W. Browne, jr., read a paper on Recent Developments in Industrial Chemistry in the South, in which several industries were selected and described as illustrations of the great progress that is being made. Special reference was made to the manufacture of sulphuric acid and of ice, preservation of timber, utilization of pine and bagasse in paper making, extraction of rice oil, introduction of improved varieties of sugar cane, and manufacture of alcohol from molasses.

The committee on uniformity in technical analysis submitted a report which showed opportunities for improvement in analytical work in this country. Samples of argillaceous limestone were submitted to a large number of analysts throughout the United States, the results reported showing decided want of agreement in many of the determinations, especially Al_2O_3, MnO, and Na_2O.

A paper on the Filtration and Purification of the Mississippi River Water at New Orleans was read by J. L. Porter. The problem was considered one of engineering, requiring the removal of 100 tons of mud daily from the 4,000,000 gal. of water necessary to supply the needs of the city of New Orleans. The most satisfactory treatment was found to be preliminary subsidence for 12 hours, coagulation with sulphate of alumina, and filtration. Softening of the water by the use of lime was also considered desirable.

The Availability of the Phosphoric Acid of the Soil was discussed in a paper by G. S. Fraps. The use of water, carbonated water, 1 per cent acetic acid, and two-hundredth normal hydrochloric acid as solvents was considered unsatisfactory. A

relation was observed between the chemically available phosphoric acid and soil deficiency in phosphoric acid, as shown by pot tests in a number of soils. Cotton and cowpeas were found to render more of the phosphoric acid of the soil available than rice or corn.

The same author presented a paper on The Effect of Climate on the Composition of Cotton Seed. Observations made during two seasons showed that cotton-seed meal from the western part of Texas, where the climate is semiarid, was richer in nitrogen than meal from the eastern part of the State. Texas cotton-seed meal was considered richer than cotton-seed meal from other sections.

The Fermentation of Sugar Cane Products was the subject of a paper by C. W. Browne, jr. Various changes brought about in sugar cane by enzyms and micro-organisms were described. The number of micro-organisms producing decomposition of sugar-cane products was considered almost unlimited. The most common fermentation of the raw juice in Louisiana is a fermentation designated as viscous, mucilaginous, or mannitic. The gum produced in this fermentation and known as dextran was believed to be either a hydrated product or a polysaccharid isomeric with either raffinose or stachyose. A fermentation in Louisiana resulting in the formation of cellulose from sugar was described. Both the dextran and cellulose resulting in the above were believed to be assimilation products rather than true fermentation products.

The scum forming on molasses in hot rooms was found to contain in one instance 27.5 per cent of fat which agreed very closely in its physical and chemical constants to butter fat. Its distinguishing characteristics from butter fat were the high degree of acidity and the greater preponderance of such acids as caproic and caprylic. Reference was also made to the common occurrence of dimethyl ketol, or acetyl-methyl carbinol, which compound was believed to be always produced in small amounts whenever the alcoholic fermentation was arrested through the development of oxidizing or acid-producing bacteria.

In a paper on The Quantitative Determination of Salicylic Acid, by W. D. Bigelow and W. L. Dubois, an attempt was made to define as exactly as possible the conditions to be followed in the estimation of salicylic acid, by extracting the organic solvents and comparing the color given with ferric solutions with that of solutions containing known amounts of salicylic acid. It was believed that with proper precautions results can be obtained which are reasonably accurate.

Papers on the Ripening of Oranges and Persimmons, by W. D. Bigelow, H. C. Gore, and B. J. Howard, were presented in abstract form. Oranges increase in actual weight of total solids and sugars from the beginning to the full maturity of the fruit. At all stages of the growth of the fruit, the total sugars are divided about equally between reducing sugar and sucrose. The marc of the orange is formed very early in its history and remains constant in weight during its growth and development. The acids are also formed at an early stage and apparently increase gradually but almost imperceptibly.

Storage of the fruit at all stages of its development results in slight loss of total sugar, a marked increase of reducing sugar, and a corresponding loss of sucrose. The loss of total sugar is to be explained by the consumption of reducing sugar as a result of the respiration of the fruit. The weight of marc remains practically constant, and the weight of acid appears to decrease slightly on storage during the various stages of the development of the orange.

The weight of the pulp of persimmons increased steadily during the entire period of observation, and a marked increase was also noted in the case of total determined solids, sugar, and marc. The sugar was found to consist almost entirely of invert sugar. The amount of sucrose was apparently almost within the limits of analytical error. The percentage of acids was also very low. During a later portion of the

period of observation, the tannin was found to decrease in proportion to the increase in the weight of the marc.

The tannin is not decomposed and does not actually disappear in the ripening of the fruit, but is converted into an insoluble form by a change of its constitution or composition, or by its combination with some substance of very low molecular weight within certain specialized cells. No evidence was found of the combination of tannin with any other body in the formation of this insoluble compound. The changes occurring on storage were similar to, but more rapid than, those occurring in the natural ripening of the fruit. Decreases were found in the solids and sugar of the stored fruit, while the weight of marc in the fruit was found to increase owing to the tannin becoming insoluble.

A paper on The Cotton Oil Industry of the South, by D. Schwartz, dealt with the pressing, refining, grading, and uses of cotton-seed oil. It was estimated that 75 per cent of the annual production of 120,000,000 gallons of oil is used for food purposes.

J. H. Long reported Investigations on Salts of Casein. He endeavored to determine by physical methods certain constants which might be considered as characteristic of casein from the milk of different species. The determinations made were (1) the equivalent weight by titration with $\frac{1}{10}$ alkali, using phenolphthalein as an indicator, (2) the electrical conductivity of the salt solution so obtained and of salt solutions made with half this amount of alkali, (3) the optical reduction of the salt solutions, and (4) the behavior of the casein on digestion with pepsin and hydrochloric acid, and the changes in the conductivity of the digesting mixtures. Determinations on casein prepared from cows', goats', and human milk were reported. Considerable differences were found in the equivalent weight of casein from goats' and cows' milk.

F. C. Weber reported experiments on The Influence of Salicylic Acid on the Excretion of Urea and Uric Acid, showing that salicylic acid given in quantities of $\frac{1}{4}$ to $\frac{1}{2}$ gm. daily did not increase the excretion of urea and uric acid to the extent claimed by many investigators.

F. G. Benedict, in a paper on The Cutaneous Excretion of Nitrogenous Material, stated that the cutaneous elimination of nitrogenous material in a healthy man amounted to about 71 milligrams per day. A man subjected to heavy labor showed an elimination of 220 milligrams per hour, which rate could be maintained for 6 hours. The experiments indicate that this channel of elimination can not be ignored in studying nitrogen metabolism.

A paper on The Effect of Alcohol on the Secretion of Bile, by W. Salant, was presented in abstract and indicated that moderate amounts of alcohol are helpful to digestion, while large amounts are injurious.

Among the other papers on the programme, many of which were read merely by title, were the following: Recent Experimental Researches on Osmosis, by L. Kahlenberg; Laboratory Designing and Construction, by W. L. Dudley; Separation of Solutes from Solvents by Absorbing Media, by F. K. Cameron and J. M. Bell; Molecular Absorption, by F. K. Cameron and B. E. Livingston; Absorption of Potassium, by O. Schreiner and G. H. Failyer; Absorption of Phosphates from Solutions, by O. Schreiner and G. H. Failyer; Electrolysis and Endosmosis in the Study of Rock Decomposition, by A. S. Cushman; A Method for the Determination of Small Amounts of Copper in Water, by E. B. Phelps; A Trade Waste Study: Copper Salts in Irrigation Waters, by W. W. Skinner; On the Presence in Soils and Subsoils of Substances Deleterious to Plant Growth, by F. K. Cameron and B. E Livingston; The Estimation of Hydrocyanic Acid in Cassava, by C. C. Moore; Artificial Coloring Matter in Whiskey, by P. H. Walker; A Uniform Method for the Determination of Dextrose and Invert Sugar, by P. H. Walker; The Extraction of Tanning Materials for Analysis, by F. P. Veitch and H. H. Hurt; The Dextrose Equivalent in

Saturated Cane Sugar Solutions and its Application in the Extraction of Sucrose, by L. W. Wilkinson; The Relation of Carbon Dioxid Excretion to Body Weight, by G. O. Higley; The Separation of Proteoses and Peptones from the Simpler Amido Bodies, by W. D. Bigelow and F. C. Cook; Studies on the Banana, by L. B. Mendel and E. M. Bailey; Use of Porcelain Dishes in Silicate Analyses, by F. L. Kortright; The Determination of Silica, by N. Knight; Solubility of Gypsum in Solutions of Ammonium Sulphate, by J. M. Bell and W. C. Taber; and Solubility of Gypsum in Solutions of Magnesium Sulphate, by F. K. Cameron and J. M. Bell.

Through the personal efforts of C. W. Browne, jr., and R. E. Blouin, of the Sugar Experiment Station at Audubon Park, and C. E. Coates, of Baton Rouge, very pleasant and profitable excursions were made by the visiting chemists to acid and fertilizer works, the Sugar Experiment Station, Kenilworth Plantation, Henderson Sugar Refinery, and the National Rice Mills.

Botanical papers.—Of the botanical papers presented few were of special interest in their direct bearings upon agriculture. The Preparation of Nontoxic Distilled Water was described by B. E. Livingston, and The Leaf Anatomy of Some Desert Plants, by F. E. Lloyd. A paper by D. T. MacDougal reported investigations on the origin of species. Various chemical solutions were injected into ovaries just before the flowers opened. Seeds maturing in ovaries so treated produced, in many instances, plants which showed a marked variation from the parental type.

The Botanical Society of America, the American Mycological Society, and the Society for Plant Morphology and Physiology were consolidated under the name of Botanical Society of America.

Section F, Zoology.—C. H. Merriam, vice-president of the association and chairman of the section, delivered an address on the subject, Is Mutation a Factor in the Evolution of the Higher Vertebrates? In a study of more than a thousand species and subspecies of North American mammals and birds no evidence was found in support of the theory of the origin of species by mutation. A Mendelian Character in Cattle was the title of a paper by W. J. Spillman. The other papers before this section were not of particular agricultural interest.

Social and Economic Science.—There were three well-attended sessions of Section I on social and economic science, one of which was devoted to papers on agricultural problems, one to educational and sociological matters, and one to railway questions.

At the session devoted to agriculture, Judge Eugene Williams, of Texas, presented a paper on The Possibilities of Cotton Warehousing from the Producers' Standpoint. He advocated the erection of warehouses by the cotton producers so that the raw product might remain in the district of production until actually wanted for use. This arrangement would protect the cotton from the elements and do away with present unbusinesslike methods of handling. The cotton grower would be enabled to sell directly to the manufacturer instead of through a middleman.

The benefit to the farmer from the adoption of this plan, which is heartily indorsed by the Southern Cotton Growers' Association and Farmers' Union, was estimated at $100,000,000 annually. Damage by exposure alone is estimated at from 50 cents to $1 per bale, or $5,000,000 to $10,000,000 annually for the total crop. An instance was cited in which cotton thus housed and sold in bulk brought from $\frac{1}{8}$ to $\frac{1}{5}$ cent per pound, or 60 cents to $1 per bale, more than if sold by the single bale from the farmer's wagon. To give confidence to the farmers the warehouses should be within easy distance and have a capacity of about 1,000 bales, rather than erect larger houses in cities. The local warehouse would add increased deposits in the local banks and encourage cotton mills in the cotton belt.

In the discussion of this paper Le Grand Powers stated that less care is exercised in the production and handling of cotton from the producer to the consumer than any other farm crop, and that proper handling would add at least one-third to the farm price and farm value of the crop.

A paper entitled Factors Determining the Price of Sugar was read by F. R. Rutter. He discussed principally the deviations in the price of sugar in the United States from the world price. The price of raw sugar at New York, after paying shipping charges and import duties and allowing for difference in grade, is frequently lower than the price of sugar at Hamburg for exportation. This decline is most marked from December to June of each year, due to the heavy imports of Hawaiian and Cuban sugar, which, together with the Louisiana output, more than suffices for the current need of refiners. The temporary excess in the supply results in a temporary reduction in domestic prices below the parity of the world price. From July to December recourse is necessary to sugar subject to the full tariff rates, especially Java and German sugar.

Louisiana is under a special disadvantage, since 80 to 85 per cent of its total output is sold in November, December, and January when the price paid for refined grades is 13 to 19 cents per 100 lbs. less than the New York quotations, due to shipping charges. The reduction in the price of raw sugar below what is termed the normal affects only indirectly, if at all, the price of refined. The price of refined sugar in New York is usually kept materially above the cost of imported German granulated sugar after allowing for shipping charges.

W. R. Dodson addressed the section on the Utilization of the By-products of the Cane Sugar and Rice Mills. The process of manufacture by which rice hulls, rice bran, and rice polish are obtained was described, and the value of these various materials for stock feeding and other purposes was discussed. One bag of rice was stated to yield from 8 to 10 lbs. of rice polish and about 30 lbs. of rice bran. From the total rice crop of Louisiana about 24,000,000 lbs. of rice polish, worth about $375,000, and 90,000,000 lbs. of bran should be obtained.

Much of the rice polish is exported to Germany and manufactured into buttons and sundry small articles. In Louisiana it is extensively used as a feeding stuff. As the result of investigations made to show the feeding value of rice bran, the price has risen from $4–$6 per ton to $14–$15. The value and use of molasses as a feeding stuff was discussed in considerable detail. This material is now widely used to bring up the carbohydrate portion of rations unusually rich in protein.

A paper on Teaching Agriculture in Rural Schools was presented by W. F. Massey. He stated that as at present constituted our rural schools do not prepare students for courses in agriculture. This preparatory work must, therefore, be done by the agricultural college, as a result of which it requires 4 years to do 2 years real college work. School gardens were considered of great usefulness in cultivating habits of industry and respect for labor. The great problem at the present time is to enthuse and train teachers for the work, encouraging to the utmost the capable ones already interested in teaching.

The Relation of Forests to Soil and Climate was discussed by W. R. Lazenby. Because of the destruction of forests nine-tenths of Ohio is required to produce what three-fourths of the State formerly did; soils rapidly lose their summer moisture; springs and wells are failing; streams and rivers are more variable in their flow; droughts are more severe and floods more common. European experience was cited to show that from one-fourth to one-third of any considerable area should be occupied with trees. In Ohio the ratio of wooded to cleared land is about 1 to 10, and the forests are still being removed.

It was urged that land which can not be cultivated or is now cultivated at a loss be set aside for timber growing, and that for every tree cut down two better ones be planted until one-fourth of the area of the timber-growing sections of the United States be restocked with trees. It was argued that if the efforts of farmers were concentrated on smaller areas larger, better, and more remunerative crops would be secured.

Miss Louise K. Miller delivered an illustrated lecture before the section on School Garden Work in Cleveland, which was stated to be the outgrowth of the efforts of the Home Gardening Association. School gardening now constitutes a regular department of the Cleveland city schools. Last year the schools sold 250,000 penny packages of seed to the school children of the city, reaching some 50,000 homes. The school children are given instruction in the laying out of gardens, preparation of soil, use of fertilizers, methods of planting seed, making cuttings, constructing hotbeds, habits of injurious and beneficial insects, etc.

Society for Horticultural Science.—The number in attendance at the New Orleans meeting of the society was small, but a large number of unusually interesting papers were presented.

The presidential address by Prof. L. H. Bailey dealt with the recent progress in American horticulture, covering the period since 1902. This progress, Professor Bailey held, had been largely along the line of further development of work already established, rather than in the projection of entirely new lines. Distinct progress has been made in teaching agriculture in schools and in presenting horticulture and country-life subjects to the people in an attractive way by means of periodicals and books. There have been published during the past three years nearly 600 bulletins on horticultural subjects.

In technical horticulture plant breeding is occupying unusual attention. The work of Mr. Burbank was characterized as remarkable and significant, but often sensationalized and overstated.

Many new horticultural regions, particularly trucking in the Gulf coast and fruit-growing in the west and northwestern States, are being developed. Fruit fully mature but still firm has been found to keep longer and better in cold storage than green or immature fruit. The large losses of citrus fruits in California by decay have been found to be due to carelessness in clipping the stems and delay in putting the fruit into storage.

In a comprehensive paper on Light as a Factor in Plant Culture, V. A. Clark discussed the effects of various colored lights, of direct and diffused sunlight, and of various artificial lights on the growth of plants. The red rays of the spectrum in general promote vegetative growth, particularly that of the leaves, while the more refrangible blue rays act upon the molecular structure of the plant, giving rise to mutations. In arid regions direct sunlight is injurious to many plants and the successful culture of such plants depends upon furnishing them with partial shade.

Leaf growth is largest and tenderest in light of rather low intensity, a fact which suggests the desirability of growing salad plants in partial shade, or better still in red light. From observations in Arizona it is believed that the intensity of direct sunlight is greater than the intensity most favorable to bud formation, and that better results would be obtained with very light shading on the south and southwest sides of fruit trees. A sorghum hedge was found too dense for this purpose and the use of sesbania, a native tall, thinly branching herb, was suggested. Volatile oils appear to develop best in red light. Hence, flowers grown for fragrance might be grown in a combination of red and blue light.

Strong light has been found in some instances to inhibit the growth of pollen tubes. This is thought to be the reason why tomatoes and cucumbers do not bear fruit in midsummer in Arizona. Strong direct sunlight in summer also prevents chlorophyll formation. Thus, strawberries in Arizona are yellow for about three months in summer even when grown under shade of cheese cloth. When grown on the north side of a dense shade of sorghum or cotton the plants remained green and dense all summer and were the most vigorous in the garden. It was believed that the matter of shading is of greater horticultural importance in arid regions than fertilization is in the East. The paper contained a number of suggestions on methods of analyzing light and methods of growing crops under partial shade.

L. C. Corbett presented a paper on Horticultural Botany. This should give us uniform detailed descriptions of our cultivated varieties of fruits, vegetables, and ornamental plants, together with a systematic classification and arrangement of such varieties. In a description of horticultural varieties such matters, in addition to the usual descriptive notes, should be included as the history of the variety, its parentage and line of descent, and its behavior in breeding experiments—whether possessing a dominant or recessive character, etc.

The Irrigated Orchards of the Western States formed the subject of a paper prepared by M. B. Waite. This pointed out the increasing importance of orcharding in the Rocky Mountain Plateau and the adjacent arid regions of the western half of the United States, and called attention to some of the differences between these sections and the humid eastern United States. Large orchard plantings, particularly of apples and peaches, have recently been made in Colorado Utah, Idaho, Montana, and New Mexico, more especially on the western slope of the Rocky Mountains and around the Great Basin at elevations of 4,000 to 6,000 feet. The important characteristic of these orchard regions is the absence of rain during the growing season, accompanied by a very low atmospheric humidity. These conditions exert a marked influence on the texture, quality, and appearance of the fruit. Apples have a beautiful wax-like color. The varieties grown are mostly of the better sorts, such as Jonathan, Rome, Winesap, etc.

The irrigated orchards of these regions are among the healthiest and thriftiest in the whole country. The air is so dry that ordinary blights and leaf spots are seldom injurious. Pear blight, however, is often more severe than in the East. Root diseases are quite prevalent, and certain insects like the codling moth are unusually serious. The orchards are unusually productive, a good crop of fruit being secured practically every year. This feature is helping a great deal in the commercial success of the industry.

Some interesting observations were forwarded to the society by W. Paddock. From some experiments made at the Colorado Station he questions whether eastern potato scab may not be due to Rhizoctonia rather than to Oospora. He suggests that Oospora may often be a parasite upon Rhizoctonia and not actually concerned in the scab at all. It is believed that the whole subject of potato scab is very much in need of investigation. In Colorado the scab, which appears to be due to Rhizoctonia, is much more severe in land which is lacking in decaying vegetable matter. A few crops of alfalfa turned under largely corrects this tendency.

N. E. Hansen gave an interesting account of a visit to Luther Burbank. Burbank was said to make constant use of the principle laid down by Darwin that excess of food causes variation.

U. P. Hedrick presented the results of an experiment designed to test the effects of superheated soils on plants. The work was carried out in a greenhouse on cucumbers. Bottom heat was supplied in bench beds, the soil of one section being kept at an average temperature of 70.8° during one experiment, a second section at 73.8°, and a third section at 83.3° F. The plants in the soil kept at the highest temperature came up about 3 days earlier than those kept in the bed at medium temperature and 6 days earlier than those in the bed kept at the low temperature. There was about the same difference in time in the formation of true leaves.

The plants bloomed in the hot bed in 35 days, in the medium hot bed in 39 days, and in the cold bed in 44 days. The first mature fruits were picked from the hot bed in 74 days, from the medium hot bed in 77 days, and from the cold bed in 82 days from seeding. The average number of fruits was slightly more in the medium hot soil and they were a little larger than in either of the other beds.

Commenting on these results Professor Hedrick stated that they represented but one experiment, only 12 plants were used in each bed. There was much variation in the behavior of individual plants in the same bed, and there was a slight difference

in the position of the beds. So far as he knew the results represented the first recorded work along this line designed to secure definite data regarding the best soil temperature at which to grow various greenhouse crops. All that is available at present is the dogmatic assertion of gardeners that this or that plant should have brisk or mild heat or none at all.

H. P. Gould forwarded a paper on the Significance of Fruit Surveys. He considered a fruit survey as involving "a study of varieties with special reference to their requirements; a study of conditions with special reference to this influence on varieties; a correlation of the factors brought out in these two lines of investigation with regard to cause and effect." A commercial fruit grower no longer asks for a best variety, for in its broad sense it is known not to exist, but rather for a variety which will best serve a particular purpose under definite known conditions. A fruit survey should furnish information along these lines.

Scientific Problems Confronting the Horticulturists of Louisiana was the title of a paper presented by F. H. Burnette. The desirability of breeding up later and more hardy varieties of fruits was emphasized. Breeding experiments with apples seem to indicate that varieties will be secured by this means which are adapted to the needs of Louisiana growers. More early pecans are needed. The control of fungi is a serious problem in Louisiana and resistant varieties are needed. Some oaks have been found upon which mistletoe has not been able to gain a foothold. Seedlings of these are being grown to see if this character can be perpetuated.

A paper by David Fairchild was presented on The Japanese Method of Ripening Persimmons, from which it appears that the ripe persimmons grown according to the Japanese method are as firm in texture as a Northern Spy apple, free from astringency, and of a delicious flavor. Investigations as to methods of curing ripe persimmons show that the Japanese put the persimmons in sake (Japanese beer) casks as soon as the casks are emptied. The heads of the casks are immediately replaced and the package made air-tight. In from 5 to 15 days, according to weather conditions, the persimmons are cured and can be removed and marketed, keeping in a firm, edible condition for a long period.

It was believed that if Americans wish to cure persimmons according to the superior Japanese method it would be advisable to make casks of southern cypress and saturate them with first-class sake imported from Japan. Casks containing sake which has been fortified with alcohol or other spirits have been found useless for the purpose of curing persimmons.

A paper entitled Forcing Rhubarb in the Dark was presented by W. R. Lazenby. The main point brought out was the very satisfactory results that may be secured by growing the roots from seed and forcing when 1 year old. Drying the roots was found to have about the same effect as freezing. Either drying or freezing serves the same purpose as a long rest, which is otherwise required, and the growth is more vigorous. When thus grown in darkness the leaf blade is greatly reduced, the green color is wholly absent, the texture is more crisp and delicate, due to a lessened development of woody fiber, the skin is much thinner than when grown in light, the water content is increased 6 to 10 per cent, and the flavor is generally improved.

C. B. Smith gave a Review of Horticultural Progress in France, in which he summarized the experimental data that have appeared in that country during recent years on such subjects as the etherization of plants, methods of pruning by disbudding, and the results secured in the culture of the Uruguay potato (*Solanum commersonii*).

T. V. Munson presented a paper on Improvement of Quality in Grapes, considering the subject from the standpoint of improvement by cultivation, by selection of kinds, and by breeding or hybridization. Much the larger part of the paper was devoted to the latter phase of the subject. Work of this kind necessitates an accurate knowledge of the characteristics of each of the 16 species of grapes and of the

many kinds of varieties that have been developed. Mr. Munson described his own methods of work in the field, illustrating the subject by a detailed account of the production of the variety Brilliant in which the Delaware and Lindley varieties were used as parents, the work being done along well-known lines.

Association of Economic Entomologists.—The society had a three days' meeting at New Orleans, beginning January 1, which was well attended. The programme was a long and varied one.

President H. Garman of the society was unable to attend the meeting, but sent a carefully prepared paper on The Scope and Position of Economic Entomology Among Branches of Biology. He maintained that as a culture study and for memory training entomology surpasses the dead languages, and should have a coequal place in schools and colleges with botany. The relation of insects to human and animal diseases, he argued, should be worked out by the entomologists, and not left to physicians and veterinarians. The desirability of using honey bees in class room work in all agricultural colleges was urged, and it was suggested that the entomologists should take the lead in teaching the silkworm industry in this country. State inspection work should be placed in the hands of trained entomologists and the nursery inspection laws of the States made more uniform. Special attention was called to the desirability of giving more study to the relation of insects to the distribution of plant disease, and to the production of flowers, fruits, etc. A point brought out in the discussion of this paper by S. A. Forbes was that apples sprayed with arsenic kept much better in cold storage than unsprayed apples.

In a paper on The Corn Root Aphis and Its Attendant Ant, Prof. S. A. Forbes gave an elaborate account of the life history of the aphis, showing its dependence upon ants for spread and injuriousness, and brought out the fact that in treating it rotation and extra cultivation should be the prime factors.

Prof. E. D. Sanderson read a paper on National Control of Introduced Insect Pests, in which he suggested that the association take action looking toward the national control of introduced insect pests.

One of the most important sessions was devoted to a symposium on the boll weevil in which W. D. Hunter discussed The Present Status of the Mexican Cotton Boll Weevil; W. E. Hinds, Laboratory Methods in the Boll Weevil Investigation; and W. Newell, The Work of the State Crop Pest Commission of Louisiana on the Cotton Boll Weevil. A. F. Conradi had a paper on The Cultural System in the Light of Recent Observations Regarding the Boll Weevil. In general, it was believed that while the progress of the insect could be temporarily checked it could not by any means now at hand be stayed, and that the weevil would eventually infest the entire cotton-producing region of the United States.

It was brought out that the cotton leaf worm, which was at one time classed as a dangerous enemy to cotton, might be useful as an ally against the boll weevil, since if allowed to develop at the end of the season it would strip the plant of all green material, necessitating the early hibernation of the weevils. If the stalks of the plants are then gathered and burned large numbers of weevils will be destroyed. Chief reliance, however, must be placed in the use of early-maturing varieties, thorough cultivation, and such cultural methods as will hasten the crop to maturity as early in the season as possible.

In the report of W. E. Hinds on Some Breeding Experiments with Boll Weevils in Cages Kept at Different Temperatures, it was shown that it is possible to predict the number of broods that may be expected in a given locality provided weather records are obtainable. It was thought further that this method of breeding at different temperatures might be applied to other insects in predicting their development in new localities where weather records were known.

W. E. Britton discussed Methods of Destroying the Woolly Maple Leaf Scale by Spraying. This scale, *Phenacoccus acericola*, is now a serious pest of the sugar maple

street trees in Connecticut cities. Some badly infested trees began to drop their leaves in July. Two small trees and one medium-sized tree were sprayed August 4 with the ordinary kerosene emulsion diluted nine times. Results were unsatisfactory, few of the insects being killed. Some trees were sprayed again August 17 with kerosene emulsion made with a soft naptha soap and diluted five times, with satisfactory results.

The same speaker gave the results of Tests of Lime-Sulphur Washes in Connecticut in 1905. In this work 6,000 peach, pear, and apple trees were sprayed in March and April, 1905, with lime-sulphur washes prepared according to 5 different formulas, and with the kerosene-limoid mixture, containing 25 per cent of kerosene. The lime-sulphur washes gave more satisfactory results than the limoid mixture and were less expensive. No advantage could be detected by adding salt to the boiled wash. The self-boiled wash, containing 20 lbs. lime, 10 lbs. sulphur, 10 lbs. sodium sulphid, and 40 gal. water, was fully as effective as any of the boiled mixtures.

Grain Fumigation with Hydrocyanic Acid was the subject of a paper by H. E. Summers. He reported that in the fumigation of a seed warehouse of 300,000 cu. ft. capacity, 1 oz. of cyanid per 100 cu. ft. was used. The house was subjected to fumes of this strength over night, but it proved ineffective against *Calandra granaria* in the middle of bags of grain.

Another paper along similar lines was presented by C. L. Marlatt on The Use of Sulphur Dioxid as an Insecticide. He described an apparatus by means of which sulphur dioxid could be forced into buildings, and its penetrating power thus increased over the simple burning of sulphur in the building. Sulphur dioxid is considered cheaper than hydrocyanic-acid gas, less dangerous to use, more effective as an insecticide, and possessing a greater penetrating power when acting on like exposed areas. A small quantity of gas acting for a long time appears to have greater insecticidal value than a large quantity acting for a shorter period. It is believed that the gas will prove especially useful as an insecticide on shipboard.

Wilmon Newell gave the results of some observations upon a little-known insect enemy of cotton and corn (*Cicada nigriventris*). This insect did considerable injury to cotton on bottom lands in the Ouachita Valley during the past season. It is controlled by cultural methods.

A paper was presented by C. E. Sanborn on The Relation of Descriptions to Economical Methods of Eradication in the Family of Aphididæ, in which he called attention to the faulty descriptions of the different species of these insects.

A. W. Morrill presented Some Observations on the Spined Soldier Bug (*Podisus maculiventris*), in which descriptive notes were given and data as to variation in male and female, the number of eggs laid by the female, percentage which hatched, etc.

Entomological notes for the year from Texas were presented by A. F. Conradi; from Cuba, by M. T. Cook; from New York, by E. P. Felt; from Ohio, by A. F. Burgess; from New Hampshire, by E. D. Sanderson; from Georgia, by R. I. Smith and A. C. Lewis; from Maryland, by T. B. Symons; and from Minnesota, by F. L. Washburn.

Other papers presented before the society were as follows: The Problem of Wing Origin and Its Significance in Insect Phylogeny, by H. Osborn; Preliminary Observations on the Variation of *Utetheisa venusta*, by M. T. Cook; Observations upon the Migrating, Feeding, and Nesting of the Fall Webworm (*Hyphantria cunea*), by E. W. Berger; The Care of Entomological Types, by T. D. A. Cockerell; History of Economic Entomology in Hawaii, by J. Kotinsky; The More Important Economic Aleyrodidæ and The Life History and Habits of *Tisheria malifoliella*, by A. L. Quaintance; and Notes and Experiments with Insecticides, by E. P. Felt, S. A. Forbes, and A. F. Burgess.

A committee of five was appointed to confer with the Bureau of Entomology to devise a plan to bring about uniform rules for nursery inspection and to cooperate

with a similar committee from the Association of Horticultural Inspectors in devising a plan to secure authority for the inspection of all plants at the port of entry, to secure authority for the eradication and control of all species of insects which may enter, and to bring about a uniformity of regulations for nursery inspection either by Federal law or by uniform State laws.

A. H. Kirkland, of Massachusetts, was chosen president for the ensuing year, and A. F. Burgess, of Ohio, secretary-treasurer.

The American Forestry Association.—The American Forestry Association met in Washington, January 16, and held a two days' meeting, at which a number of interesting papers were read, officers elected, and considerable routine business performed. The president of the association, Secretary of Agriculture James Wilson, opened the meeting by a brief address, in which he called attention to the work of the association and of the forest service along forestry lines during the past year. Reforestation, in his judgment, should proceed at the rate of a million acres per year. To the forester every day of the year should be Arbor Day. The relation between the reclamation service and the forest service was pointed out. The reclamation service deals with the land below the ditch, while the forest service works above the ditch and seeks to preserve the waters for irrigation and manufacturing purposes.

Rev. Edward Everett Hale stated that in the matter of forestry the nation can do what the State or the individual can not do. The Government alone is in a position to make long-time investments, and should be the agent in establishing and maintaining forest reserves.

Mr. Bainbridge, representing the New York Manufacturing Association, spoke on the relation of forestry to the postal laws, in which he showed that 2,000,000 lbs. of second-class matter go through the post-offices in the United States every day in the year. About one-half of this material goes into the wastebasket. This means that 3,000,000 lbs. of forests go to waste each day. This kind of matter is allowed to go through the mail at 1 ct. per pound, while all other kinds cost 16 cts. per pound. It was believed that if these rates were adjusted more equitably less quantities of paper material would be wasted and our forests be protected to this extent.

Samuel B. Elliott called attention to the fact that the Canadian government last year gave away 7,000,000 forest trees to its people for planting purposes, and suggested that this Government might do something along a similar line.

A number of speakers discussed various phases of the Appalachian and White Mountain forest reserves. The association favored the combining of the four bills now before Congress relative to these reserves, and the supporting of one bill asking for $3,000,000 to purchase land for these reserves.

Several papers were read by representatives of the reclamation service in which the work of that service and various projects now under way were discussed. It appears that there are 13 projects now under construction and 10 more in view for the coming spring, at a total cost of $30,000,000. By 1908 it is expected that 1,250,000 acres of land will be under irrigation. This will accommodate about 20,000 families. Each community thus established will be directly interested in the preservation of water, and therefore in the maintenance of forests about the headwaters, since forests are essential to a continuous even flow throughout the year.

Secretary Wilson was reelected president for the ensuing year. A number of changes were made in the by-laws, by which the society will become more closely affiliated with the State forestry organizations and other societies interested in forestry matters.

Referees of Official Agricultural Chemists.—The referees appointed for this year are announced as follows: *Phosphoric acid,* B. W. Kilgore, Raleigh, N. C.; *determination of n trogen,* J. H. Gibboney, Blacksburg, Va.; *separation of nitrogenous bodies,* R. Harcourt, Guelph, Canada (milk and cheese proteids); *potash,* A. L. Knisely, Corvallis, Oreg.; *soils,* R. H. Loughridge, Berkeley, Cal.; *dairy products,* F. W. Woll,

Madison, Wis.; *foods and feeding stuffs*, J. K. Haywood, Washington, D. C.; *food adulteration*, A. E. Leach, Boston, Mass.; *sugar* (special analytical methods), C. A. Browne, jr., Audubon Park, New Orleans, La.; *tannin*, H. C. Reed, Stamford, Conn.; *insecticides*, G. E. Colby, Berkeley, Cal.; *inorganic plant constituents*, W. W. Skinner, Washington, D. C.; *medicinal plants and drugs*, L. F. Kebler, Washington, D. C.

The following are the associate referees: *Phosphoric acid*, J. M. McCandless, Atlanta, Ga.; *determination of nitrogen*, C. L. Penny, Newark, Del.; *separation of nitrogenous bodies*—meat proteids, F. C. Cook, Washington, D. C., and vegetable proteids, Harry Snyder, St. Paul, Minn.; *potash*, B. B. Ross, Auburn, Ala.; *soils*, J. H. Pettit, Urbana, Ill.; *dairy products*, J. M. Bartlett, Orono, Me.; *foods and feeding stuffs*, John P. Street, New Brunswick, N. J.; *food adulteration*—colors, E. F. Ladd, Agricultural College, N. Dak.; saccharine products, including confectionery, C. H. Jones, Burlington, Vt.; fruit products, H. C. Lythgoe, Boston, Mass.; wine, Julius Hortvet, St. Paul, Minn.; beer, H. E. Barnard, Indianapolis, Ind.; distilled liquors, C. A. Crampton, Washington, D. C.; vinegar, R. B. Fitz Randolph, Trenton, N. J.; flavoring extracts, E. M. Chace, Washington, D. C.; spices, A. L. Winton, New Haven, Conn.; baking powder and baking chemicals, W. M. Allen, Raleigh, N. C.; meat and fish, E. L. Redfern, Lincoln, Nebr.; fats and oils, L. M. Tolman, Washington, D. C.; dairy products, A. E. Leach, Boston Mass.; cereal products, A. McGill, Ottawa, Canada; infants' and invalids' foods, W. D. Bigelow, Washington, D. C.; vegetables, H. V. Tartar, Portland, Oreg.; condiments other than spices, R. E. Doolittle, New York; cocoa and cocoa products, E. M. Bailey, New Haven, Conn.; tea and coffee, C. D. Howard, Concord, N. H.; preservatives, W. L. Dubois, Washington, D. C.; and determination of water in foods, F. C. Weber, Washington, D. C.; *sugar*—molasses methods, J. E. Halligan, Baton Rouge, La., and chemical methods, L. S. Munson, Washington, D. C.; *tannin*, F. P. Veitch, Washington, D. C.; *insecticides*, W. B. Ellett, Blacksburg, Va.; *inorganic plant constituents*, John W. Ames, Wooster, Ohio; *medicinal plants and drugs*, Charles H. La Wall, Philadelphia, Pa.

Agricultural Education in France.—The French Ministry of Agriculture issued a decree December 20, 1905, establishing a professional dairy school at Surgeres (Charente-Inférieure), under the direction of M. Dornic, director of the dairy station at that place.

A winter school of agriculture has been established at Troyes (Aube). The course of study is to extend over 2 winter terms running from November to March. This year, however, the school did not open until January 3.

A poultry husbandry school has been established at Gambais (Seine-et-Oise), and opened its doors for the first practical course of 3 months February 1.

Agricultural Education in Germany.—The enrollment of students for 1905 in a number of German institutions shows a large increase over the enrollment for 1904. At the Agricultural High School in Berlin there are enrolled for the winter term 893, as compared with 865 in 1904; at the Agricultural Academy at Bonn 501, as compared with 422 in 1904, and at the University of Breslau the agricultural students number 140, as compared with 129 in 1904.

An agricultural winter school was opened December 1, 1905, at Seelow, under the direction of Dr. Weiss.

The Penn School.—This school for negroes, which was established in 1862, is located on St. Helena Island, off the coast of South Carolina. At a recent farmers' conference held under its auspices attention was called to the important progress made by the school in directing the farming and improving the agricultural conditions of the island and of adjacent territory in Beaufort County. P. W. Dawkins, a graduate of Hampton, is in charge of the agricultural work.

Agriculture in the Common Schools.—Nine hundred and two teachers in attendance at the Michigan State Teachers' Association, December 29, adopted the following res-

olution: This association heartily favors the incorporation of elementary agriculture in the common school curriculum as rapidly as possible and in so far as limiting conditions may permit. This association believes that this is an available means to the end of interesting the rising generation in the natural, mechanical, scientific, and social inheritance of the greatest industry; and that by this means an increasing number of the brightest children will come to see in agriculture an attractive field for the satisfaction of life's ambitions. The possibilities of agriculture as an industry from which the educational process itself may be enriched are also recognized.

Elementary Agriculture in the Common Schools of Ohio.—Prof. A. B. Graham, of Ohio State University, states in the January number of the Agricultural Student that over 250 townships have already adopted elementary agriculture as a part of their course of study, and that about 10 high schools have taken similar action. The State commissioner of schools has considered this work of sufficient importance to give credits for agriculture in his grading of the high schools.

Boys' Corn-Growing Contest.—More than 100 boys have entered a corn-growing contest to be conducted in 1906 in Laporte County, Ind., under the auspices of the County Farmers' Institute Association. As a preliminary to this contest the contestants attended the local farmers' institute February 2 and 3, at which a corn school was conducted. Each boy will grow 1 acre of corn, and the contest will be closed with the awarding of prizes aggregating $300 in value.

Reading University College Poultry Farm.—A description of the poultry farm at Theale, carried on in conjunction with the University College of Reading, England, is given in the December number of the Agricultural Economist. The farm consists of nearly 50 acres of land and is provided with an excellent equipment, which is assembled in an incubator house, a brooder house, scratching sheds, a cramming shed, portable poultry houses, and a plucking and trussing shed. Six breeds of chickens and 1 of ducks are raised.

Publication of Names of Dealers in Adulterated Seeds.—The Attorney-General has decided that the Secretary of Agriculture has the right to publish the names of seedsmen who adulterate their product, and that such publication does not render him liable for criminal libel. The Department has been publishing such information, and the law providing for the seed inspection makes the publication mandatory.

A New Food Journal.—The first number of a new monthly publication, entitled *The American Food Journal*, has just been published in Chicago. This has for its object the dissemination of information regarding the State pure-food laws, investigations which have a bearing on the effects of preservatives, coloring matters and similar topics, and in general the publication of data which will serve to further the interests of officials in charge of the enforcement of pure-food laws, manufacturers who are desirous of producing high-grade goods in compliance with legal requirements, and dealers who handle food products. A feature of the journal, it is stated editorially, will be the collection of data regarding Federal and State pure-food laws, the publication of reports of conventions of pure-food chemists, and related material.

New Poultry Journal.—A new poultry journal, entitled *Poultry Husbandry*, began publication in January. The journal is to be a monthly and is published at Waterville, N. Y. Among its contributors are several men now or formerly connected with the experiment stations.

Miscellaneous.—Prof. Samuel Fraser, of Cornell University and Station, has decided not to accept the appointment in the Bureau of Soils, mentioned in the last issue. He will take up the management of W. A. Wadsworth's estate, at Geneseo, N. Y., to carry out some improvements outlined by him in a report to Mr. Wadsworth last summer, as the result of a thorough agricultural survey of the estate and the system of management followed.

Dr. W. Krüger, vice-director of the agricultural chemical experiment station at Halle and chief of the bacteriological section, has been appointed director of the

Bernburg Station, made famous by the work of Hellriegel and Wilfarth on nitrogen assimilation by legumes. He has also been given the title of professor.

It is noted from *Science* that Dr. Pehr Olsson-Seffer, for the past two years instructor in botany in Stanford University, has been selected to take charge of a botanical station in tropical Mexico for the investigation of problems connected with the cultivation of rubber and coffee. The station is established by companies which own twelve large plantations in the region where it is to be located, devoted to the raising of rubber and coffee.

The Carnegie Institution has established a department of botanical research, to include the Desert Laboratory and other botanical projects. Dr. D. T. MacDougal, assistant director of the New York Botanical Gardens, has become director of the newly organized department.

The North Carolina Agricultural and Mechanical College for the Colored Race has recently completed a new laboratory for soil physics, which is well provided with apparatus for determining specific gravity, apparent specific gravity, volume weight, porosity, and other characteristics of soils.

The market-day lectures, delivered under the auspices of the County Technical Laboratories at Chelmsford during 1904–5, reference to which has previously been made, have been published in abstract by the Essex Education Committee.

Studley College Agricultural Journal is the title of a new journal issued by Lady Warwick's agricultural college. In the first number J. C. Medd points out a new opening for students of that college and the college at Swanley as teachers of nature study in village schools. Several counties are said to be appointing peripatetic teachers of nature study to attend to groups of adjacent schools, and it is predicted that with a sufficient supply of efficient teachers, demand for their services will steadily increase.

O

EXPERIMENT STATION RECORD.

VOL. XVII. MARCH, 1906. No. 7.

The efforts which are making for the promotion of agriculture in India are described in the initial number of *The Agricultural Journal of India*, which has recently come to hand. The leading article in this new journal is by the inspector general of agriculture in India, and reviews the history of the movement to improve the condition of agriculture in that country, the present status of this work, and the plans for future development. It is a decidedly interesting and instructive article, and shows that the government of that country is thoroughly aroused to the desirability and importance of aiding its basic industry by means of research, education of different grades, demonstration, and close contact with the farmers.

The machinery for conducting this work already exists, and hence it becomes largely a matter of extending these agencies and increasing their efficiency. The organization for agriculture includes an imperial department of agriculture, with headquarters at Calcutta, and a system of provincial departments of agriculture, each presided over by a director, and to a certain extent independent of the imperial department. This system has grown out of the inquiries and recommendations made by the famine commissions of 1866 and 1880, and in organization has naturally followed the main division of the general administration into imperial and provincial departments.

The imperial department is presided over by the inspector-general of agriculture and the assistant inspector-general. The staff includes the director and principal of the agricultural research institute and agricultural college at Pusa, and several specialists, among them an agricultural chemist, a cryptogamic botanist, a biological and economic botanist, an entomologist, an "agri-horticulturist," and an "agri-bacteriologist." There are eight provincial departments of agriculture located, respectively, in the provinces of Bombay, Madras, Bengal, United Provinces of Agra and Oudh, Punjab, Central Provinces, Assam, and Burma. Each department has a director and a deputy director, frequently an assistant director, and an irregular number of specialists. In several cases inspectors and botanists are carried upon the staff, and the Bengal department has indigo and jute specialists, while the Bombay department has an agricultural chemist.

The duties of the provincial departments include the keeping of land records, which requires the collection and examination of agricultural statistics for each village and district, as a basis for the assessment and collection of revenues levied upon land. These departments also have important duties in connection with the famine relief, including furnishing the administration with the fullest information regarding the condition of every agricultural section and its people, and in seasons of scarcity they carry their inquiries to every village and assist in the actual work of relief.

The provincial departments of agriculture also include a veterinary branch, which consists of one or more qualified officers with European degrees in veterinary science, and a large native staff of veterinary inspectors and assistants. The principal duties are the investigation, control, and treatment of cattle diseases, and the improvement of the breeds of cattle. There are numerous veterinary dispensaries in the towns, and much work is done in the villages. There are also veterinary colleges at Lahore, Bombay, Madras, and Calcutta, and schools in some other provinces.

Although this provincial veterinary work is under the control of the local directors of agriculture, the imperial branch of the civil veterinary department is separate from the department of agriculture, being managed by an inspector-general. Similarly, the great irrigation works of the government, which are on the largest scale to be found in any country, are managed independently of the imperial department of agriculture, being a branch of the public works department; and the forestry interests are in charge of the forest department. There are also imperial and provincial departments of meteorology, which maintain weather stations for record and prediction, and a botanical survey of India has been in progress for many years. So that all told the field is quite fully covered in organization.

In recent years both the imperial and provincial departments have made rapid progress in the direction of the improvement of agriculture by means of investigations and experiment. In 1903 the government of India sanctioned the establishment of an imperial agricultural research station, which is located at Pusa in Behar, the most thickly populated agricultural tract of the Bengal Presidency. The station has fully equipped laboratories for research work, and stands at the head of the India system of experiment stations and farms. With it is connected a higher agricultural college, an experimental farm, and a cattle breeding farm. The institute is located on a government estate of 1,358 acres, and the buildings now in progress will cost considerably over a half-million dollars, toward which has been applied a portion of the donation of $150,000 made by Mr. Henry Phipps, of this country, to which reference has previously been made. The organization of this staff, composed of European specialists with native assistants, has now been completed.

The college will be the capstone of the system of agricultural education in India. It will provide specialized post-graduate courses in the hope that the best of the native students will ultimately be fitted for the higher appointments in the imperial department. It will also provide men with a good agricultural education for employment in the regular government service, and as agents and managers for owners of estates and the like. It is expected that the college will be ready to start work about the end of 1907.

The farm will provide facilities for field experimentation and for the practical training of students, and it is hoped that it will serve as a model for similar farms under the provincial governments. The cattle farm is intended to furnish good bulls for distribution to the adjoining tracts of Bengal, for the improvement of the indigenous breed of cattle.

It is also the intention that the expert staff of the Pusa institute shall conduct higher lines of research work applicable to all parts of India, and beyond the capacity of the provincial departments. Moreover, this staff will render assistance to the provincial experts in their several branches, train young scientists for future employment as provincial experts, and stand at the head of their respective departments in the agricultural college.

The system of experiment stations and farms in India includes, in addition to the research institute at Pusa, thirty-nine establishments in seven different provinces. These are of different grades, some being general experiment stations, others devoted mainly to a particular line, like cotton, tobacco, rice, sugar, fibers, or tropical fruits, and others to sewage farming, irrigation work, alkali reclamation, cattle breeding, and sericulture. There are eleven of these stations in Bombay, seven in Madras, nine in Bengal, five in the United Provinces of Agra and Oudh, two in Punjab, three in the Central Provinces, and two in Assam.

The institutions for agricultural education include, besides the agricultural college at Pusa, a college of agriculture at Saidapet, Madras, with farm attached, a college of science at Poona, and agricultural schools at Sibpur (Calcutta), Cawnpur, and Nagpur.

In pursuance of the policy inaugurated by the establishment of the Pusa institute and agricultural college, it is planned to greatly extend the work of the other agricultural colleges and experiment stations, and of the provincial departments of agriculture. To this end an additional grant of about $660,000 has been made, which it is hoped to increase in future years. This grant will almost treble the present expenditure. The plans for development include an experimental farm or station for each important distinct agricultural tract. This

will mean a very large increase in these farms, each of which will be in charge of a trained native assistant, with the necessary helpers.

It is proposed to strengthen the expert staff of each provincial department of agriculture so as to include one or more superintendents of farms, an agricultural chemist, economic botanist, mycologist, and entomologist. The superintendent of farms in each province, or deputy director, will be an expert agriculturist and will be in charge of a "circle," which in the case of large provinces will comprise only a part of a province. In his circle he will supervise all agricultural work, including the experiment stations, demonstration plats, the testing and distribution of seeds, implements, and special manures. He will also be in close touch with the cultivators, and will be the guiding spirit of the agricultural associations of his circle. He will be assisted by the workers at the experimental farms and a peripatetic staff. The specialists at the provincial experiment station will not only conduct investigations in their laboratories and on their farms, but will tour throughout the province, visiting all the local experiment stations and farms, directing the work connected with their special branches, and inquiring into local conditions.

It is further proposed to locate an agricultural college in each important province, with a course of technical training extending over three years. In the past the personnel of the agricultural colleges has been inadequate, so that their influence on agricultural improvement has been small. The main result of the colleges has been to turn out students with some knowledge of agriculture, who have been largely absorbed into the several branches of government revenue administration. It is believed now that the demand for graduates will be sufficient to induce a larger number of students to attend, as the field for the trained agriculturist is said to be broadening. The course in the provincial agricultural colleges will lead up to the specialized post-graduate course at Pusa.

Considerable attention will also be given to the dissemination of information, especially the results of agricultural investigation and their application in practice. Temporary demonstration plats will be started, district agricultural associations will be organized, agricultural shows will be subsidized, the distribution of improved seed, implements, and manures will be extended, and popular publications in the vernacular will be issued. It is pointed out that there are many difficulties in the way of agricultural improvement in a country like India, where most of the land is divided into small holdings and cultivated by men with no capital and little education; but by the means enumerated it is hoped to bring the work into closer touch with the actual farmers, and make it of more immediate use to them.

As a further concentration of effort it is proposed to separate the land records branch of the provincial departments, and to appoint a

separate director of agriculture, who will be in charge of the agricultural and veterinary branches, thus relieving the departments of a line of work which has made serious demands upon them in the past. In the imperial department of agriculture it is proposed to increase the number of specialists for the investigation of important special crops or problems, as cotton, wheat, sugar, tobacco, fruit, etc. This will enable coordinating the work in different provinces, assisting the provincial experts in various ways, conducting experiments in the improvement of varieties by selection and breeding, and promoting special agricultural industries.

Several years will be required to introduce this scheme for the expansion of the imperial and provincial departments of agriculture in its entirety, but the condition of the finances of the country is said to be such as to warrant the development of this important work. That its value is now being appreciated is indicated by the statement that "one of India's shrewdest merchant princes has described expenditure upon scientific agriculture as the most promising investment that government can make."

As one means of extending the influence of the imperial and provincial departments of agriculture, the government of India has sanctioned the publication of *The Agricultural Journal of India*, which will be issued from the agricultural research institute at Pusa. The journal will be a quarterly and will be devoted to matters of interest to the general reader, while more strictly scientific and technical papers will be published in a second series entitled *Memoirs of the Department of Agriculture in India*. The inspector-general of agriculture will act as editor, assisted by the advisory committee of the Pusa staff.

While the new journal and the memoirs will thus be the official organs of the imperial department, they will not be confined to articles contributed by their workers. The work of the provincial departments has often been buried in annual reports and other official publications, which have rarely been readily available to the public and not always in a form for general use.

The new journal will form a permanent record of the practical results of agricultural research throughout India. It will also serve as a medium of communication between the officers of the several departments, thus relieving in some measure the isolation which exists at present. It is hoped by the administration that the journal will appeal to the outside public and the leading agriculturists in India, who will thus be kept in touch with agricultural progress in the country and will be able to test and practice more advanced methods and the application of science to agricultural problems. The initial number is interesting and attractive, and augurs well for the success of the venture from the editorial standpoint.

NEW HORTICULTURAL BUILDING AT THE MASSACHUSETTS AGRICULTURAL COLLEGE

Wilder Hall, the new building for the department of horticulture and landscape gardening at the Massachusetts Agricultural College, was erected with an appropriation of $39,950 made by the State legislature a year ago. The proposition to provide such a building at the college had been pending for nearly three years at the time the appropriation became available, and during that time all the questions connected with the building had been thoroughly studied from various points of view, and the plans had been more than usually well matured. This long period of preparation, therefore, resulted in securing a building more perfect in its appointments than could otherwise have been devised. It was built by local contractors, who began work upon it June 21, 1905.

The building is located on a gravelly slope to the east of the college campus and adjoining the grounds of the department of horticulture. The natural incline of the land is such as to allow a basement almost entirely above ground on the west, making the building on that side apparently one story higher than on the east. Advantage has been taken of this in the arrangement of the rooms of the building, as will be seen by the accompanying plate. (Plate I.)

The building is constructed of red brick with terra-cotta trimmings, and modern fireproof methods and materials have been used throughout. The nonbearing partitions are of fireproof tile, the bearing partitions of brick, and the floors of hollow fireproof tile. The staircases are of Portland cement on hollow fireproof tile, and many of the floors are finished in Portland cement. The roof is of green tile on wooden trusses, the latter being the only exception to the fireproof construction. The building is thoroughly constructed, and is very substantial in all respects. It is devoted entirely to the department of horticulture and landscape gardening, and has a total floor space of nearly 10,000 square feet, a very large proportion of which is available for use.

The basement floor (fig. 2) contains two class rooms, a storage room, and two laboratories, besides hallways and toilet rooms, a coat room,

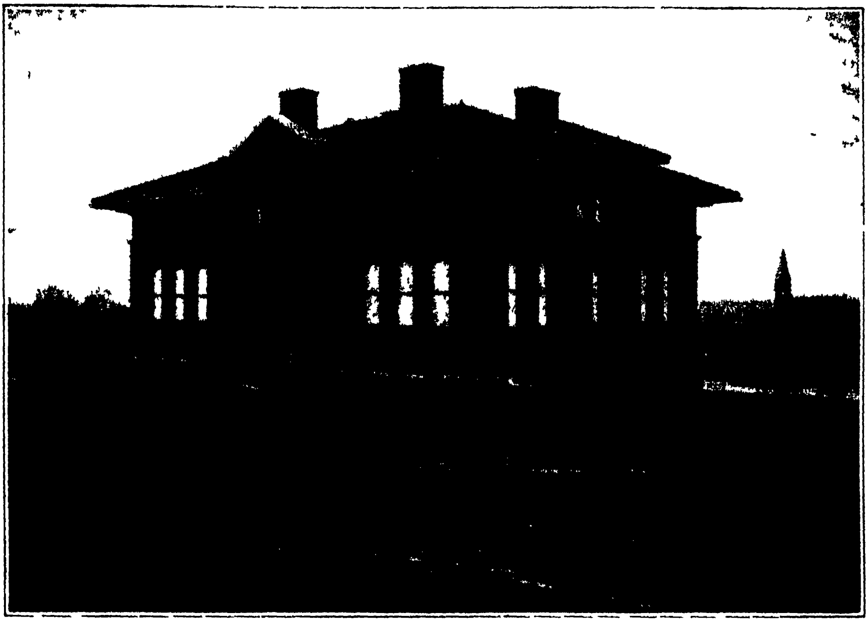

FIG 1.—WILDER HALL—EAST FRONT.

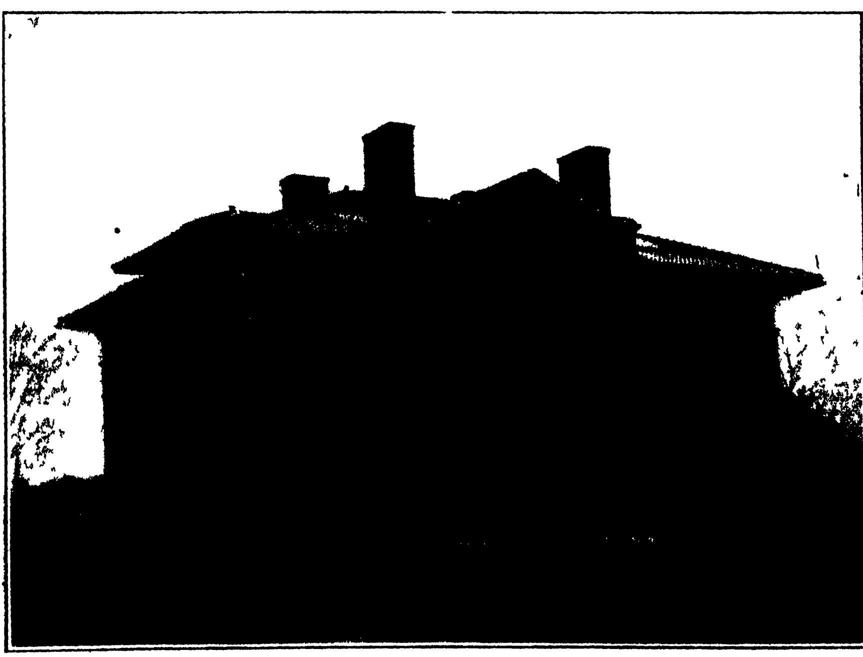

FIG 2.—WILDER HALL—WEST FRONT.

and a room for surveying instruments. The entrance to the basement is on the western front and is on a level with the ground. This front is toward the college campus and is the natural entrance for students. As the class rooms and laboratories for the larger classes are located on this floor, the movement of large bodies of students up and down stairs and through the hallways is avoided and there is no disturbance of work which may be in progress on the other two floors of the building. Only small classes of advanced students are provided for on the upper floors.

The first, or middle, floor (fig. 3) opens on the ground level on the east side of the building. This is the side on which the grounds of the department of horticulture are located, and the principal office looks directly out upon the grounds. Between the offices of the head

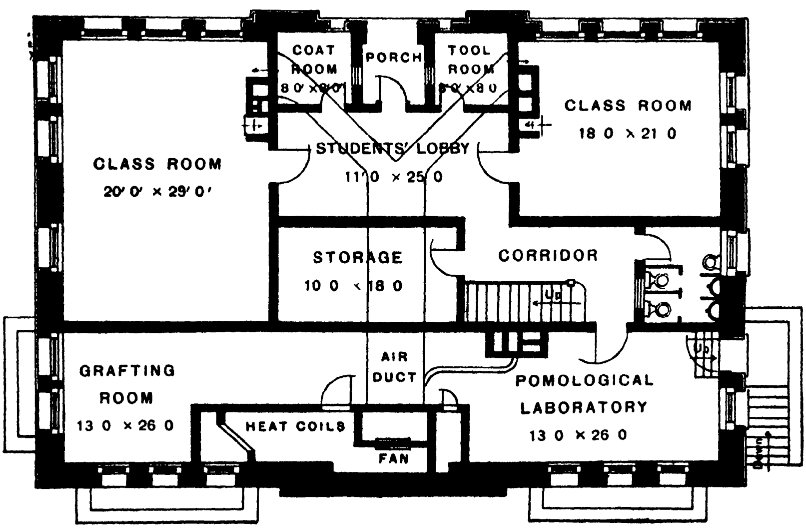

FIG 2.—Basement plan

of the department and the assistants is a small room for records, experimental files, etc. At the other end of the floor are a museum, and a laboratory for senior students in horticulture, with a reading room adjoining in which horticultural periodicals and reference books will be kept. This suite will constitute a sort of club room for the advanced students and form a meeting place for seminars. Provision is made in the center of the western side for a winter conservatory.

The upper floor (fig. 4) contains a large drafting room for landscape gardening, as the work in this course is largely done on drafting tables. There is also a large class room fitted with drawing tables, photographic rooms, a private laboratory, and quarters for a janitor. This floor is well lighted, there being four large skylights in addition to the windows.

The building will be equipped with the most modern furniture and apparatus. It is heated from the central heating plant of the college,

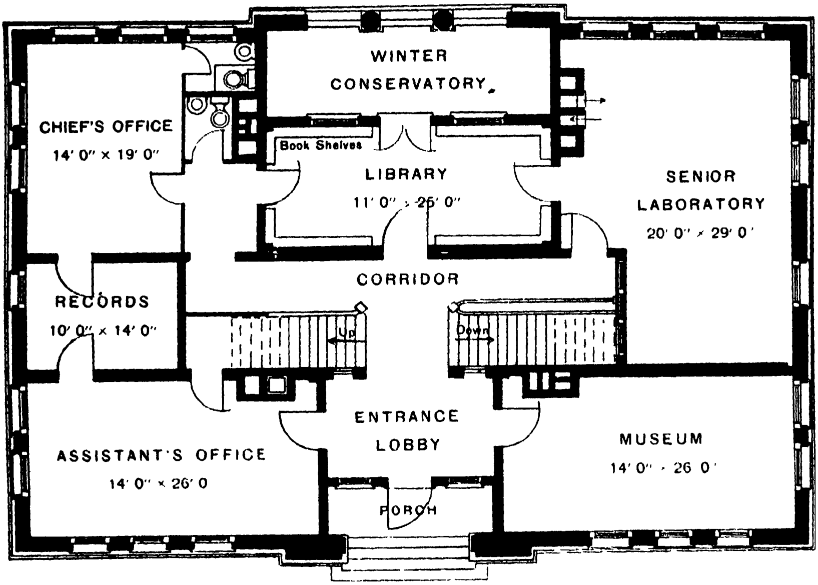

FIG. 3.—First-floor plan.

and a very complete system of positive ventilation has been installed. The building is named in memory of Hon. Marshall Pinckney Wilder,

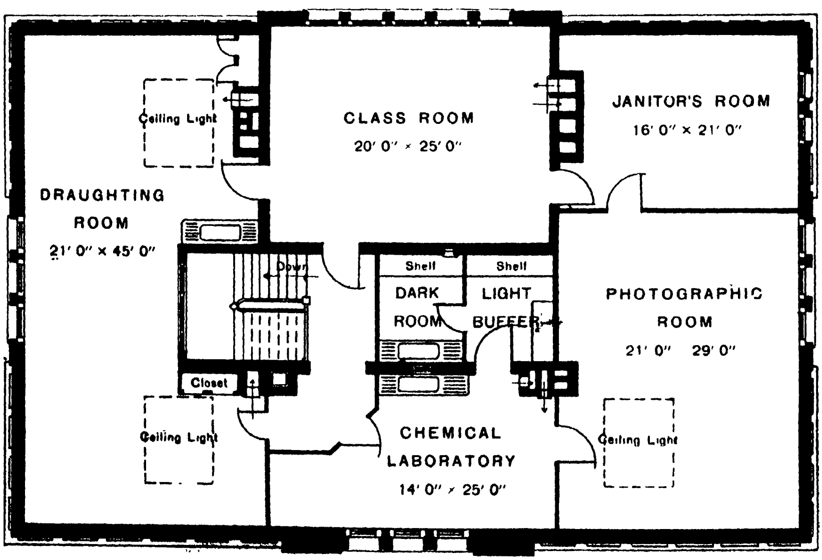

FIG. 4.—Second-floor plan.

of Massachusetts, widely known for his services to horticulture, and for twenty-three years a trustee of the college.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Agricultural chemistry during the first half of the year 1905, W. ZIELSTORFF (*Chem. Ztschr., 4 (1905), Nos. 21, pp. 491–495; 22, pp. 505–507*).—This article notes especially the work of König, showing the importance of physical factors in soil fertility; of Lemmermann on the relation of volume of soil to plant growth; of Ewert on the influence of light and copper-lime solutions on metabolism in plants; of Sjollema on the isolation of the colloid substances of soils and the use of coloring matters in soil investigations; of von Seelhorst on the influence of soil moisture on the growth of oats; of Loew et al. on the lime requirements of plants; of Meyer on the injurious effect of gypsum on plants grown in zinc pots; of Weitz on the use of nitrate of soda as a fertilizer; of Frank, Rösler, Löhnis, and Tacke on the use of lime nitrogen as a fertilizer; and of von Lepel on the preparation of nitrites and nitrates by electrical discharges and on the use of the product as a fertilizer.

A number of minor articles are also referred to on experiments with fertilizers of various kinds, including lime, marl, magnesia, steamed Thomas slag, Peruvian guano, ammoniated superphosphate, Thomas-ammonium-phosphate lime, etc. Recent investigations relating to animal nutrition are also reviewed Most of the articles mentioned have been noted from time to time in this journal.

Formation of oceanic salt deposits. XLIII, Calcium content of the constant solutions at 25°, J. H. VAN'T HOFF and W. C. BLASDALE (*Sitzber. K. Preuss. Akad. Wiss., 1905, No. 34, pp. 712–714; abs. in Jour. Chem. Soc. [London], 88 (1905), No. 516, II, p. 641*).—"This paper concludes the investigation in so far as calcium compounds at 25° are concerned, and the composition of all constant solutions, when saturated with the particular calcium salt with which the solutions are in equilibrium, is tabulated. For the sake of simplicity, gypsum, glauberite, and syngenite are the only salts taken into consideration, but the quantities of calcium found in the solutions can not, however, on this account differ appreciably from the true equilibrium values."

Comparative study of methods of analysis of fertilizers in different countries, L. SICARD (*Ann. École Nat. Agr. Montpellier, n. ser., 5 (1905), No. 2, pp. 111–147*).—This is the second part of a report on this subject dealing with methods of determining phosphoric acid.

A method for the determination of black alkali in irrigating waters and soil extracts, W. W. SKINNER (*Jour. Amer. Chem. Soc., 28 (1906), No. 1, pp. 77–80*).—The method described for this purpose is a modification and adaptation of the method proposed by Hehner as a substitute for the Clark process for determining hardness of waters.

Two hundred cc. of the water or soil solution is evaporated to dryness in a platinum or silver dish, with 50 to 150 cc. of fiftieth-normal sodium carbonate solution. The residue is rubbed up with distilled water free from carbon dioxid, the volume being made up to 100 cc. Fifty cc. of this solution, which has been allowed to stand until it is clear, is titrated with fiftieth-normal sulphuric acid, adding 5 cc. of chloroform and 1 cc. erythrosin as indicator.

"If less sulphuric acid is required than that necessary to balance one-half of the sodium carbonate added . . . the difference in cubic centimeters between the sulphuric acid required and one-half of the sodium carbonate added is multiplied by the factor 0.00136, which gives the equivalent of calcium sulphate in 100 cc. of the water. But if, on the other hand, more sulphuric acid is required than that equivalent to one-half of the sodium carbonate added, then black alkali was originally present in the solution, and the difference in cubic centimeters is multiplied by the factor 0.00106, which gives the black alkali in terms of sodium carbonate in 100 cc. of water. . . .

"While not strictly correct, custom and practical considerations sanction the expression of black alkali in terms of sodium carbonate. The method described yields satisfactory results for black alkali and also for the antidote for black alkali—i. e., soluble salts of calcium and magnesium, which for irrigation purposes should be expressed in terms of calcium sulphate."

Determination of the strength of solutions used in nitrogen determination, F. MACH (*Landw. Vers. Stat., 63 (1905), No. 1–2, pp. 71–80*).—Comparative tests of potassium tetroxalate, sodium hydroxid, and ammonium sulphate are reported which show that potassium tetroxalate and ammonium sulphate tend to give results somewhat over the average, sodium hydroxid somewhat below.

The determination of the organic nitrogen in sewage by the Kjeldahl process, E. B. PHELPS (*Jour. Infect. Diseases, 1905, Sup. 1, May, pp. 255–272*).—Experiments are reported which indicate that a strong oxidizing agent, such as potassium permanganate, potassium bichromate, or aqua regia, added before digestion is completed causes a decided loss of nitrogen, but may be safely added after the digestion is completed. The substitution of copper sulphate for mercury is proposed, as it obviates the necessity for the subsequent addition of sodium sulphate. The method proposed is in brief as follows:

Digest 100 cc. of the sewage with 5 cc. of sulphuric acid and 0.1 gm. copper sulphate until the yellow color has entirely disappeared; add small crystals of potassium permanganate, one at a time, until the green color of the precipitate is permanent; cool the contents of the flask, and make up to 500 cc. with ammonia-free water. To 10 cc. or more of the solution, according to the nitrogen content, add an equal amount of ammonia-free water, make strongly alkaline with a saturated solution of sodium carbonate equal to half the amount of the acid mixture, and distill over 50 cc. by blowing steam through the solution. Determine ammonia in the distillate in the usual manner by nesslerization.

On the determination of nitric and nitrous acids, J. MEISENHEIMER and F. HEIM (*Ber. Deut. Chem. Gesell., 38 (1905), No. 15, pp. 3834–3837, fig. 1*).—The authors describe a method suggested by Kalman, which is based upon the measurement of the nitric oxid (NO) set free when nitrous acid is treated with hydrogen iodid and when nitric acid is treated with ferrous chlorid and hydrochloric acid in the usual way. In mixtures of the two the nitrous acid is decomposed first by the addition of the hydrogen iodid, and the nitric acid remaining in the solution is subsequently decomposed by addition of ferrous chlorid and hydrochloric acid, the operation being carried on in an atmosphere of carbon dioxid, and the nitric oxid evolved in each stage being measured. A number of tests of the method are reported which show close agreement between the calculated percentages and those found by analysis.

The determination of nitrous acid, F. RASCHIG (*Ber. Deut. Chem. Gesell., 38 (1905), No. 16, pp. 3911–3914*).—It is pointed out that the method described by Meisenheimer and Heim (see above) is the same in principle as that which has long been used by the author except that instead of measuring the nitric oxid the author titrates, after the lapse of at least 2 minutes, the separated iodin, the latter procedure being much quicker than the former.

On the determination of nitric and nitrous acids, J. MEISENHEIMER and F. HEIM (*Ber. Deut. Chem. Gesell., 38 (1905), No. 17, p. 4136*).—A reply to the above statement of Raschig that the principle of the method proposed by the authors is not new, in which it is maintained that the only original feature claimed for the method is the determination of nitric and nitrous acids in the same solution.

Change in the German official method of estimating nitric acid in meat and meat products, K. FARNSTEINER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 6, pp. 329, 330*).—The author concludes that the Schlösing-Wagner method should be used in the estimation of nitrites in meat and meat products.

The quantitative estimation of nitric acid in meat, W. STÜBER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 6, pp. 330–335, fig. 1*).—Comparative tests showed, in the author's opinion, that the Schlösing-Wagner method for estimating nitrites in meat gave satisfactory results even for the determination of very small amounts and that the presence of organic nitrogenous bodies did not exercise any unfavorable effect.

Judging meat extracts on the basis of the organic phosphorus present, M. SIEGFRIED and E. SINGEWALD (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 9, pp. 521–527*).—On the basis of analytical data which are reported the authors conclude that the quality of meat extract may be judged by estimating the total phosphorus and organic phosphorus present, since it has been found that when the extract spoils organic phosphorus is converted into inorganic forms.

A study of the proteins of the castor bean, with special reference to the isolation of ricin, T. B. OSBORNE, L. B. MENDEL, and I. F. HARRIS (*Amer. Jour. Physiol., 14 (1905), No. 3, pp. 259–286*).—The chemical study of the castor bean, which is reported, indicates, in the authors' opinion, that it contains proteins of the same character as the other oil seeds which have been examined, namely, (1) a considerable quantity of a crystallizable globulin, (2) a much smaller amount of a coagulable albumin, and (3) proteoses. The elementary composition and reactions of these substances were studied.

"The physiological properties—marked toxicity and agglutination of blood corpuscles—ascribed to the substance known as ricin are associated with the coagulable albumin of the castor bean. This protein was isolated in a state of considerable purity without impairment of its solubility or physiological action, and an improved method for the separation of ricin is thus introduced.

"Our ricin preparations retain a considerably higher toxic power than those heretofore described, a limit of 0.001 mg. per kilo being exceeded as a fatal dose in rabbits."

Studies of the nature of strawberry fat, J. APARIN (*Zhur. Russ. Fiz. Khim. Obshch., 36 (1904), pp. 581–596; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 9, pp. 562, 563*).—Wood strawberries (*Fragaria vesca*) were dried and the fat extracted.

A thick oil was obtained, cloudy at ordinary temperature but clear when heated somewhat. A characteristic strawberry-like odor, probably due to the presence of an ethereal oil, was noticeable but not prominent. The strawberry oil was found to be a drying oil, and in this and other respects much resembled linseed oil. Linoleic acid constituted 81 per cent of the total acid present and linolenic acid 10.5 per cent. Only traces of oleic acid were noted.

The behavior of lecithin to ferments, P. MAYER (*Berlin. Klin. Wchnschr., 42 (1905), p. 1102; abs. in Zentbl. Physiol., 19 (1905), No. 17, p. 601*).—According to the author the lipase of intestinal juice induces asymmetric cleavage of lecithin. The modification which turns the plane of polarized light to the right is broken down in the cleavage process, while a form hitherto unknown, which rotates the plane of polarized light to the left, remains.

The curcuma reaction for boric acid, A. Goske (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 4, pp. 242, 243*).—A modification is proposed of the German official method for detecting boric acid with curcuma paper, which the author claims is delicate enough to reveal the presence of 0.001 to 0.0001 per cent.

A long, narrow strip of the paper is allowed to dip into the solution to be tested. Owing to capillary attraction the liquid rises in the paper to a greater or less height, and on the upper edge of the wet portion the red-brown color will be distinctly noticeable if boric acid is present. Soda solution turns this red-brown zone blue. This method reveals the presence of a minute amount of boric acid in many sorts of common salt, therefore it is pointed out that the character of the salt must be known in testing for boric acid in ham, bacon, etc.

The qualitative detection of boric acid, O. Mezger (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 4, pp. 243–245*).—A modification of the German official method for detecting boric acid with a hydrogen flame is proposed.

After incinerating a suitable sample (15 or 20 gm.) previously moistened with sodium-carbonate solution, a portion of the ash is tested with curcuma paper and the remainder placed in a flask with 15 to 20 cc. of methyl alcohol, the flask being fitted with a reverse condénser. Two cc. of concentrated sulphuric acid is added and the mixture warmed on a water bath at 70° for a quarter of an hour. Hydrogen gas passed through the mixture after cooling will give the characteristic green flame if borax is present.

Quantitative estimation of vanillin, J. Hanuš (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 10, pp. 585–591*).—According to the analytical data reported, nitrobenzhydrazin is the most satisfactory reagent for the quantitative estimation of vanillin in vanilla, vanilla commercial products, and extracts.

Paints and paint products, E. F. Ladd and C. D. Holley (*North Dakota Sta. Bul. 67, pp. 575–604*).—This bulletin contains information on paints and paint products, especially as regards the character of various products entering into the preparation of paints, and is occasioned by the recent State law taking effect January 1, 1906, and which was enacted for the purpose of preventing adulteration and deception in the sale of paints, which it is the duty of the director of the station and his assistants to enforce. The present bulletin deals only with white paints, while future bulletins will treat of other paints and also oils, oil substitutes, and driers. Analyses of 28 samples of paint are reported.

METEOROLOGY—WATER.

Monthly Weather Review (*Mo. Weather Rev., 33 (1905), Nos. 6, pp. 233–286, figs. 12, charts 9; 7, pp. 287–348, pls. 4, figs. 7, charts 9; 8, pp. 349–384, fig. 1, charts 9; 9, pp. 385–432, figs. 8, charts 9*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of June, July, August, and September, 1905, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 6.—Special contributions on Tornado of June 5, 1905, at Binghamton, N. Y. (illus.), by W. E. Donaldson; A Novel Type of Record Sheet Adapted to Seismographs, Aerial Meteorographs, etc., by C. F. Marvin; Observations of Atmospheric Electricity After the Eruption of Mount Pelée, May 8, 1902 (illus.), by A. W. Wright; Improved Methods for Finding Altitude and Azimuth, Geographical Position, and the Variation of the Compass (illus.); and Annual Rings of Tree Growth, by E. E. Bogue (see p. 669); and notes on the scientific staff of the Weather Bureau, inventions patented by Government employees, seismology in the United States, the Libbey circle in seismology, the Piche evaporometer (illus.), the associations of

teachers of physics and mathematics, Weather Bureau men as educators, the new edition of Hann's Meteorology, contributions to the physics of the free atmosphere, hailstorm in the Bahamas, no change of climate, explorations of the upper atmosphere by the Blue Hill Observatory, an old reference to the kite in meteorology, winds and waves, diurnal variation of atmospheric humidity, and the guango, or rain tree.

No. 7.—Special contributions on Studies on the Diurnal Periods in the Lower Strata of the Atmosphere—V, The Variable Action of the Sun and Its Effect upon Terrestrial Weather Conditions (illus.), by F. H. Bigelow; The Meteorological Work of the U. S. Naval Eclipse Expedition to Spain and Algeria, August 30, 1905, by F. H. Bigelow; Observations of Earth Temperature in Japan (illus.), by S. T. Tamura; An Account of Recent Meteorological and Geophysical Researches in Japan, by S. T. Tamura; The Variation in Minimum Temperatures on Still, Clear Nights Within the Confines of a Village (illus.), by W. I. Milham; Earthquakes Recently Recorded at the Weather Bureau, by C. F. Marvin; Tides and Thunderstorms, by J. C. Beans; Has the Rainfall of Southern California been Affected by any So-called Rainmaker? and Meteorological Records at Orono, Me., by J. S. Stevens; and notes on the pioneer forecasters of hurricanes, simultaneous weather anomalies in Iceland and Europe, the sugar beet and its climatic environment, Weather Bureau work during the eclipse of August 30, 1905, meteorology in Petermann's Geographische Mitteilungen, showers of fish, Hawaiian climatology, scientific aeronautics, mirage after sunset, a quadruple rainbow, meteor in Montana, reorganization of meteorology in Australia, the station at Port au Prince, Haiti, a severe hailstorm at Grand Rapids, Mich., meteorological course at Williams College, and a caution as to hypotheses.

No. 8.—Special contributions on The Tornado of May 10, 1905, at Snyder, Okla., by C. M. Strong; and Studies on the Diurnal Periods in the Lower Strata of the Atmosphere—VI, General Review of the Status of Cosmical Meteorology, by F. H. Bigelow; and notes on kite work in the Atlantic trade-wind region, and the impartial distribution of weather-crop bulletins.

No. 9.—Special contributions on The Lifting Power of Ascending Currents of Air, by H. H. Clayton; The West Indian Hurricane of August 11, 1903 (illus.), by M. Hall; and Japanese Meteorological Service in Korea and Manchuria (illus.), by Y. Wada, trans. by S. T. Tamura; and notes on Dr. Julian Aparicio, Pietro Tacchini, Robert August Billwiller, tornado at Carbondale, Pa., August 30, 1905 (illus.), Mohn's results of Nansen's North Polar work, meteorology in South America, E. D. Archibald and the modern kite, the Mount Weather observatory, importance of research observatories for the promotion of meteorology, mountain stations and their importance, an absurd explanation as to Indian summer, the altitude of Mount Whitney, Cal., new Canadian provinces (illus.), the green ray at sunset, and ball lightning.

Meteorological observations, J. E. Ostrander and C. H. Chadwick (*Massachusetts Sta. Met. Buls. 203, 204, pp. 4 each*).—Summaries of observations on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during November and December, 1905. The general character of the weather of each month is briefly discussed, and the December bulletin gives a summary for the year. The principal data in this summary are as follows:

Pressure[a] (inches).—Maximum, 30.86, December 1; minimum, 29.22, April 6; mean, 30.019. *Air temperature*[b] (degrees F.).—Maximum, 93, July 10; minimum, −13, January 24; mean, 45.8; mean sensible (wet bulb), 41.1; maximum daily range, 45, June 9; minimum daily range, 3, June 12; mean daily range, 22.1. *Humidity.*—Mean dewpoint, 37.3; mean relative humidity, 76.5. *Precipitation.*—Total rainfall or melted snow, 38.8 in.; number of days on which 0.01 in. or more rain or melted snow fell, 122; total snowfall, 40 in. *Weather.*—Total cloudiness recorded by sun thermometer, 1,977 hours, or 44 per cent; number of clear days, 130; number of fair

[a] Reduced to freezing and sea level. [b] In ground shelter.

days, 128; number of cloudy days, 107. *Bright sunshine.*—Number of hours recorded, 2,477, or 56 per cent. *Wind.*—Prevailing direction, west; total movement 46,442 miles; maximum daily movement, 475 miles, January 4; minimum daily movement, 1 mile, June 22; mean daily movement, 127 miles; maximum pressure per square foot, 23.5 lbs., January 4, WNW. *Dates of frost.*—Last, May 24; first, September 15. *Dates of snow.*—Last, May 1; first, November 9.

Meteorological summary for 1904, C. A. PATTON (*Ohio Sta. Bul. 163, pp. 259–272*).—This summary includes notes on the weather and tabulated daily and monthly records of observations at the station at Wooster, Ohio, on temperature, precipitation, cloudiness, direction of the wind, etc., and for comparison, similar data for previous years and for other parts of the State. The following is a summary of results:

Summary of meteorological observations in Ohio.

	For the experiment station.			
	1904.		1888–1904.	
Temperature (° F.):				
Mean		47.1		49.9
Highest	(July 17)	92.0	(Aug. 8, 1891)	99.0
Lowest	(Jan. 5)	−21.0	(Feb. 10, 1899)	−21.0
Mean daily range		21.5		20.7
Greatest daily range	(Dec. 28)	48.0	(Oct. 6, 1895)	55.0
Clear days		149.0		132.0
Cloudy days		170.0		127.0
Days rain fell		136.0		128.0
Rainfall (in.):				
Greatest monthly	(Apr.)	6.59	(July, 1896)	8.05
Least monthly	(Nov.)	.40	(Sept., 1897)	.29
Mean yearly				
Prevailing direction of wind		SW.		SW.

	For the State.			
	1904.		1883–1904.	
Temperature (° F.):				
Mean		48.6		50.7
Highest	(July 17 and Sept. 29)	99.0	(July 4, 1897)	113.0
Lowest	(Jan. 4)	−30.0	(Feb. 10, 1899, and Jan. 4, 1904).	−39.0
Mean daily range				
Greatest daily range	(Jan. 5)	54.0	(Sept. 25, 1897)	67.0
Clear days				
Cloudy days				
Days rain fell		117.0		125.0
Rainfall (in.):				
Greatest monthly				
Least monthly				
Mean yearly		35.36		37.17
Prevailing direction of wind		SW.		SW.

Report of the section of climatology of the National Irrigation Congress (*Proc. Nat. Irrig. Cong., 13 (1905), pp. 217–247*).—An account is given of the proceedings of this section at the congress held at Portland August 21–24, 1905, including the following papers:

The Influence of the Chinook on the Climate of Idaho and Montana, by E. L. Wells; Relation of Drought to Forest Fires, by A. B. Wollaber; Rainfall and Irrigation in Foreign Countries, by E. A. Beals; Precipitation Cycles on the Pacific Slope—Their Relation to Droughts and Water Supply for Irrigation Purposes, by G. N. Salisbury; Distribution of Rainfall of the State of Washington, by L. C. Cover; A Drop of Rain, by A. G. McAdie; Influence of Elevation upon Rainfall in California, by G. H. Wilson; and Climatology of the Coast Desert of Peru, by A. F. Sears, sr.

Report of the Eighth International Geographic Congress held in the United States, 1904 (*U. S. House Representatives, 58th Cong., 3. Session, Doc. 460, pp. 1064, pls. 12, figs. 58, maps 6*).—This report, delayed in publication, contains a

number of articles bearing directly or indirectly on agriculture, especially in the line of meteorology and climatology.

Among these are: Meteorological Summary for Agaña, Island of Guam, U. S. A., for the Year 1902, by C. Abbe, jr.; A Climatological Dictionary for the United States, by A. J. Henry; Scientific Work of Mount Weather Meteorological Research Observatory, by F. H. Bigelow; Suggestions Concerning a More Rational Treatment of Climatology, by R. DeC. Ward; The Canadian Climate, by R. F. Stupart; The Climate of Kimberley, by J. R. Sutton; A Project for the Exploration of the Atmosphere over the Tropical Oceans, by A. L. Rotch; Rainfall with Altitude in England and Wales, by W. Marriott; The Climatology of the Lowlands and Watershed Terraces of Natal, by F. W. D'Evelyn; The Climate of Pamplemousses, in the Island of Mauritius, by T. F. Claxton; The Climate of Ts'aidam, by A. Kaminski; Meteorology of Western Australia, by W. E. Cook; and On the Unsymmetrical Distribution of Rainfall About the Path of a Barometric Depression Crossing the British Islands, by H. R. Mill.

Precipitation and storms in the Grand Duchy Saxe-Altenburg, 1900-1904, F. KRÜGER (*Mitt. Osterlande, n. ser., 11 (1905), pp. 51-81*).—Data for monthly and annual precipitation at different places, daily and monthly distribution of rainfall, snowfall, and frequency and distribution of storms are summarized.

The influence of water vapor upon nocturnal radiation, J. R. SUTTON (*Sci. Proc. Roy. Dublin Soc., n. ser., 11 (1905), No. 3, pp. 13-33*).—The author cites evidence to show "that Tyndall's discovery of the absorption and radiation of heat by the vapor of water has been too hastily applied to meteorological problems," and summarizes the results of a series of observations at Kimberley on the absolute and relative humidity at 8 p. m. as related to the subsequent fall of temperature, from which the conclusion is drawn that there is "no trace of a fall of temperature depending upon the quantity of moisture present."

The observations "show a relationship between the nocturnal cooling of the air and the relative humidity, but not any relationship at all to the absolute humidity. . . . It is a dry air which, of itself, *à priori* because of its feeble radiative power, should cool more slowly than a damp air. We have then to establish a connecting link between these two facts. It is to be found, it seems, in the dependence of the cooling of the ground upon the hygrometric state of the air."

Observations on the surface cooling between 8 and 11 p. m. of a "bare patch of red sand" show that comparing the falls of soil temperature with the relative humidity it was found "that a simple division by three gives practically the same value as those for the cooling of the air, so long as the air is not more than half saturated. For humid states in excess of this, the air cools faster than the ground.

"The falls of earth-temperature as compared with the dew-point are of exactly the same nature in the two series as those of the cooling of the air, namely, that they increase at first to a dew-point of about 40-45°, after which they decrease again. The explanation is that the humidity of the air chances to have on the whole its minimum values when the dew-point is about 40-45°.

"We see, then, that the lower air takes its temperature chiefly from the ground, but that the great radiative power of its contained water vapor, when the relative humidity is high, lowers its temperature somewhat faster than it can absorb radiation from the ground."

Contributions to the hydrology of eastern United States, 1905, M. L. FULLER (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 145, pp. 220, pls. 6, figs. 42*).—This is the third of a series of progress reports relating to the hydrology of the eastern portion of the United States (E. S. R., 16, p. 1031). It contains the following contributions:

Hydrologic Work in Eastern United States and Publications on Ground Waters, Two Unusual Types of Artesian Flow, Construction of So-called Fountain and Geyser Springs, A Convenient Gage for Determining Low Artesian Heads, A Ground-

water Problem in Southeastern Michigan, and Notes on Certain Large Springs of the Ozark Region, Missouri and Arkansas, by M. L. Fuller; Drainage of Ponds into Drilled Wells, by R. E. Horton; Water Resources of the Catatonk Area, New York, by E. M. Kindle; Water Resources of the Pawpaw and Hancock Quadrangles, West Virginia, Maryland, and Pennsylvania, by G. W. Stose and G. C. Martin; Water Resources of the Nicholas Quadrangle, West Virginia, by G. H. Ashley; Water Resources of the Mineral Point Quadrangle, Wisconsin, by U. S. Grant; Water Resources of the Joplin District, Missouri-Kansas, by W. S. T. Smith; Water Resources of the Winslow Quadrangle, Arkansas, by A. H. Purdue; Water Resources of the Contact Region Between the Paleozoic and Mississippi Embayment Deposits in Northern Arkansas, by A. H. Purdue; Water Resources of the Portsmouth-York Region, New Hampshire and Maine, by G. O. Smith; Water Supplies at Waterloo, Iowa, by W. H. Norton; Water Supply from Glacial Gravels near Augusta, Me., by G. O. Smith; Water Supply from the Delta Type of Sand Plain, by W. O. Crosby; Waters of a Gravel-filled Valley near Tully, N. Y., by G. B. Hollister; and Notes on Certain Hot Springs of the Southern United States, by W. H. Weed.

Concise summaries of the papers are given.

The underground waters of Mississippi—a preliminary report, W. N. Logan and W. R. Perkins (*Mississippi Sta. Bul. 89, pp. 112, figs. 23*).—This is a preliminary report on the underground waters of Mississippi, embodying "present knowledge of the depth at which potable underground waters may be obtained in different parts of the State; the known and probable artesian areas of the State, and the chemical properties of the underground waters in various parts of the State."

The bulletin discusses precipitation and streams as sources of underground water supply, describes the drainage basins of Mississippi and the geological position and character of the water-bearing strata of the State, classifies the underground waters with reference to chemical position, and outlines the principal artesian areas of the State.

"The principal drainage areas of the State are: The Tombigbee basin, drained by the upper part of the Tombigbee River and its branches; the Pascagoula basin, drained by the Pascagoula River, which is formed by the conjunction of the Leaf River and the Chickasawhay River; the Pearl River basin, draining to the Gulf through Lake Borgne; the Big Black basin, draining to the Mississippi (the smallest of the basins); the Yazoo basin, draining to the Coldwater, the Tallahatchie, the Yallobusha, and the Yazoo, and entering the Mississippi, which receives the drainage of the western part of the State."

The underground waters are classified as follows: "(1) Mississippi bottoms.—The water from this region is on the whole carbonate, sodium carbonate predominating. (2) Tombigbee basin.—The waters of this basin belong to the soft-water group. The amount of solid matter usually falls below 10 gr. per gallon. (3) The northeast prairie region.—These waters are chlor-carbonate. There is a predominance of sodium carbonate and sodium chlorid. (4) The Chickasawhay basin.—The waters of this basin are carbonate waters. (5) The Gulf Coast.—The waters of the Gulf Coast are chlor-carbonate. Sodium chlorid is the predominant mineral. (6) Other parts of the State.—The waters from other parts of the State may be classed in general as soft."

The principal artesian areas are as follows: "(1) The northeastern deep-well area including the Tombigbee artesian basin; (2) the eastern deep-well area including the Chickasawhay and Leaf River artesian basins; (3) the southern deep-well area including the Gulf Coast and lower Pearl River artesian basins; (4) the northwestern deep-well area including the Mississippi bottoms and upper Pearl River artesian basins."

Subartesian water supply, W. G. Cox (*Agr. Gaz. N. S. Wales, 16 (1905), No. 10, pp. 996–1002, figs. 2*).—This article describes methods and machinery used in boring

shallow wells and developing localized subterranean supplies of water in New South Wales.

Field measurements of the rate of movement of underground waters, C. S. SLICHTER (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 140, pp. 122, pls. 15, figs. 67*).—This is a revised edition of Water-Supply and Irrigation Paper No. 67 (E. S. R., 14, p. 640), giving somewhat more detailed accounts of apparatus used and results obtained in laboratory studies, as well as of supplemental field investigations.

Destructive floods in the United States in 1904, E. C. MURPHY ET AL. (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 147, pp. 206, pls. 18, figs. 19*).—This report gives data regarding streams and drainage basin, precipitation and temperature, gage height and discharge, character and prevention of damage by floods occurring during the year on the following rivers: Sacramento River, California; Susquehanna River, Pennsylvania; Mohawk River, New York; Grand River, Michigan; Wabash River, Indiana; Belle Fourche River, South Dakota; Kansas, Neosho, Verdigris, Osage, and Arkansas rivers, Kansas; Canadian River basin, New Mexico, Oklahoma, and Indian Territory; Pecos River basin, New Mexico; Rio Grande River, New Mexico; Cache la Poudre and Crow Creek, Purgatory, and La Plata rivers, Colorado.

Similar data are also given for the Johnstown and Robinson Run floods occurring in Pennsylvania and the Troxton Canyon and Globe floods of Arizona. Observations on drought in the Ohio River drainage basin are also recorded, and a method of computing cross-section areas of waterways is described.

The normal distribution of chlorin in the natural waters of New York and New England, D. D. JACKSON (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 144, pp. 31, pls. 5*).—This bulletin discusses the physiological functions of common salt, salt (chlorin) as an indication of pollution of water supplies, methods of determining chlorin, and the normal distribution of chlorin in the natural waters of New York and New England as calculated from a large number of determinations collected from various sources.

The bulletin contains a normal chlorin map showing "isochlors" for the different States represented in the region studied. Attention is called to the fact that while chlorin is as a rule a reliable and persistent index of pollution of water "a certain proportion of the chlorin in a water has its origin in natural causes, and has no relation to artificial pollution; therefore, in determining the character of a water for domestic purposes, it is necessary to consider this natural or normal chlorin, and whenever the chlorin present is in excess of the normal the evidence of past pollution is complete.

"It has been found, moreover, that (with the exception of local deposits) the normal chlorin in natural waters is derived from the salt of the ocean, blown over the land by storms, and that it diminishes in amount as the distance from the ocean increases. This decrease is so definite that equal amounts of chlorin are found along lines generally parallel to the seacoast, thus affording a basis for the establishment of isochlors. In Massachusetts and Connecticut these lines have been located, and for several years the information has proved to be of great value to the water-supply interests of those States."

Mineral waters of the United States, J. K. HAYWOOD and B. H. SMITH (*U. S. Dept. Agr., Bur. Chem. Bul. 91, pp. 100*).—This bulletin gives the results of an attempt "to obtain all the most prominent spring waters as they are sold on the market and to compare the composition of such samples with the composition as advertised by the owners of the springs."

A further study of all well-known spring waters collected at their sources is also in progress, and the second part of this bulletin gives the results already obtained on Saratoga waters so sampled. The classification of mineral waters is discussed and the authors propose a classification which differs in certain particulars from those suggested by Peale and Crook. A method of naming mineral waters is also explained

and available knowledge regarding the medicinal value of various classes of such waters is summarized.

Descriptions are given of the analytical methods used in the following determinations: Lithium, potassium, calcium, manganese, iodin, chlorin, sodium, magnesium, iron and aluminum, arsenic, bromin, boric acid, nitric acid, sulphuric acid, carbonic acid, phosphoric acid, nitrous acid, silicic acid, bicarbonic acid, free ammonia, albuminoid ammonia, and oxygen-consuming capacity. "Besides these determinations, barium, strontium, and hydrogen sulphid were determined in cases where there was reason to suspect their presence."

Tables show analyses of 42 samples of mineral waters from leading springs of the United States represented in the open market, together with analyses advertised by the spring owner, or, where they could not be obtained, the analyses given in Crook's Mineral Waters of the United States. The hypothetical form of combination of the constituents is also given in each case, and the general character of the waters as shown by analysis is discussed. Analyses of 13 samples of water from springs at Saratoga, New York, collected by an agent of the Department, are also reported.

The results reported in the first case (with market waters) show "that the composition of waters as determined by the authors is often different from the composition as given in the advertising matter. This does not necessarily mean that there has been any attempt at fraud on the part of the owner of the spring. Sometimes the difference between the analyses may be small and immaterial, falling within the limits of error of analyses by different analysts and the natural change in the composition of the water from time to time.

"Sometimes the difference in analyses may be due to the fact that the advertised analysis was made years ago and that since that time the composition of the water has gradually but steadily changed. On the other hand, these differences may sometimes be due to poor analytical work on the part of the commercial chemist, sometimes to fraud on the part of the retail dealer, and sometimes even to fraud on the part of the spring owner."

The study of the Saratoga waters collected at the springs shows that "(1) the waters are in nearly all cases markedly weaker in mineral content than they were about 35 years ago; (2) there is a great variation in the total mineral content of individual springs from time to time; (3) the rarer elements, such as lithium and bromin, seem to vary to a greater extent than the other elements present."

Purifying drinking water by electricity, R. GUENTHER (*Mo. Consular Rpts.* [*U. S.*], *1905, No. 297, p. 128*).—This is a brief note on a simple apparatus devised by a French engineer named Otto for generating ozone by means of electricity and mixing it with the water to be purified. It is claimed that "the apparatus is capable of purifying about 60 gal. of water an hour, and the cost per hour is about the same as that of an ordinary electric incandescent light."

Copper sulphate for killing green scums, S. AVERY and A. KEYSER (*Breeder's Gaz., 48 (1905), No. 19, pp. 935, 936*).—Experiments at the Nebraska Station in tanks supplying water for stock are briefly reported, the conclusion reached being that "tanks may be kept free from green scums by treating with copper sulphate at least 3 times during the heated portion of the summer. Adding the copper sulphate directly at the rate of ½ lb. copper sulphate to 15 bbls. of water is the more effective method of treatment. Where this treatment is used the copper sulphate should be placed in a coarse sack and drawn back and forth through the water until dissolved."

Estimation of Bacillus coli in potable waters, A. GAUTIÉ (*Ann. Chim. Analyt., 10 (1905), pp. 254–257; abs. in Jour. Chem. Soc.* [*London*], *88 (1905), No. 516, II, p. 660*).—The author claims that correct estimates of the number of this organism present in water can only be made by repeated experiments with varying amounts of water (from 100 cc. to 1 drop). In other respects he follows the usual method of adding peptone broth and a sufficient amount of phenol to prevent the growth of a large number of saprophytic germs.

SOILS—FERTILIZERS.

Alkali conditions in the Payette Valley, J. S. BURD (*Idaho Sta. Bul. 51, pp. 20*).—After a brief discussion of the geography and topography of the Payette Valley, the character of the soils and waters, the occurrence of hardpan, and superficial evidences of alkali, the author reports analyses of 8 samples of well water and examinations with reference to appearance of the soil solution, texture, and percentages of sulphates, chlorids, and carbonates of 107 samples of alkali taken at different depths, from 1 to 4 ft.

The results show that the predominating alkali is of the so-called black variety. In soils whose fertility has been most affected by alkali accumulations the carbonate equivalent was frequently as great as 0.3 to 0.5 per cent, and even in the best lands, producing fine crops, the average amount of sodium carbonate was 0.1 per cent or more. In a few instances sodium chlorid was found to be present in extraordinarily large amounts, 0.5 per cent and over. In general, however, the proportion of this salt was much less than that of sodium carbonate, being only 0.03 per cent or less in good upland soils.

Soluble sulphates were frequently present in large amounts, 0.2 to 0.4 per cent, in the highly contaminated lands, but in the more productive soils they were present in small amounts, as compared with other constituents, frequently running as low as 0.02 per cent or less. The virgin soils as a rule contained smaller amounts of soluble salts in the surface foot than in lower layers. In soils containing much free water the alkali was usually uniformly distributed, but was frequently higher in the surface foot than in other layers. Geographical position seemed to have little influence in determining the character of the alkali.

In general the conclusion was reached that "the amounts of so-called alkali or water soluble salts in the soils of this valley are quite large and offer a serious obstacle to the successful farming of large areas. Prior to artificial irrigation the amounts and distribution of the alkali constituents in the various soils were fairly uniform. Since artificial irrigation commenced, however, there have been radical changes in this respect.

"Irrigation has resulted in improving certain favorably situated soils by working the salts to greater depths or into the drainage or neighboring lands; but on low-lying lands or wherever the natural underdrainage is poor accumulations have been brought about. These accumulations, as has been noted above, consist largely of sodium carbonate. Unfortunately, however, the use of gypsum, the usual antidote for sodium carbonate, is inapplicable here because the amount of resulting sodium sulphate, in addition to the sulphate and chlorid already present, would in most cases still be far above the toxic limit for the crops of this section.

"In even the most favorably situated soils the alkali is quite high, and unless water is sparingly used, or the underdrainage is exceptionally good, the tendency of the salts to come to the surface is soon observed. The topography of certain portions of the area—i. e., the bench lands—is admirably suited to artificial underdrainage, which would probably solve the alkali problem for lands so situated, if it were introduced. It is difficult to see, however, how the low-lying river lands could be successfully underdrained, and for the present at least such lands should be avoided or chosen with great care when intended for agricultural purposes."

The geological survey of Ireland, G. A. J. COLE (*Dept. Agr. and Tech. Instr. Ireland Jour., 5 (1905), No. 4, pp. 619–629, pls. 2, figs. 4*).—A brief account is given of the history, progress, and aims of this survey, which has recently been put under the control of the Department of Agriculture and Technical Instruction for Ireland. It is proposed to give special attention to surface geology and to the preparation of drift and soil maps of districts of special agricultural interest.

The soils of Montserrat, F. WATTS and H. A. TEMPANY (*West Indian Bul., 6 (1905), No. 3, pp. 263-284, dgms. 10*).—Mechanical and chemical analyses of 12 samples of typical soils of the island are reported.

It is stated that the soils of Montserrat, which are of volcanic origin, are "on the whole, fertile and easily worked; they are characterized by containing very small amounts of carbonate of lime, but, otherwise, they are not usually deficient in the elements of plant food." The mechanical analyses show that there is considerable variation in the texture of the soils, some being sandy and easily worked, others stiff and difficult to till. The suitability of the soils to sugar cane, limes, cotton, cacao, rubber, vegetables, etc., is discussed.

An illustration of the use of the wire-basket method for soil testing, F. D. GARDNER (*Science, n. ser., 22 (1905), No. 569, pp. 678-680*).—This article briefly reports a test by the wire-basket method of soil of the Orangeburg clay type from South Carolina in comparison with soil of the same type from Texas.

The results of experiments with wheat, as well as chemical analysis of the soils, indicate that the soil contained too much soluble salts for normal development of the wheat plants. Tests of samples of soils from other portions of the same field indicated that the conditions noted in the first sample were not generally true for the whole area. Neither were they true for the soil of the same type from Texas.

The absorptive power of soils, C. DUSSERRE (*Chron. Agr. Vaud, 18 (1905), No. 18, pp. 463-466*).—A brief general discussion of this subject, referring especially to the investigations of the author and T. Bieler already noted (E. S. R., 16, p. 347).

Chemical-geological investigations on the absorptive properties of decomposed rocks, M. DITTRICH (*Ztschr. Anorgan. Chem., 47 (1905), No. 2, pp. 151-162*).—In continuation of previous investigations (E. S. R, 14, p. 746), the author reports results of studies of the effect of weathering on the solubility of the various constituents of rocks in water, weak acids, and neutral salt solutions of various kinds.

A study of fresh and weathered hornblende granite showed that while the percentages of lime and soda had been decreased to a marked extent by weathering, the percentage of potash was decidedly increased. Extraction of the weathered product with water and weak acids showed that the potash was combined in highly insoluble form, the solubility in weak acids being but slightly greater than that in water. Digestion of fresh and weathered rock of various kinds with $\frac{1}{10}$ normal sodium chlorid solution resulted in solution of only a trace of potash but of considerable amounts of calcium and magnesium, the latter being replaced by an equivalent amount of sodium.

Treatment with $\frac{1}{10}$ normal potassium chlorid solution resulted in the solution of considerable amounts of calcium and magnesium, corresponding as a rule with the stage of weathering of the rock. In all cases the amounts of calcium, magnesium, and sodium removed in solution were replaced by an equivalent amount of potash. This potash was partly but not completely removed by a subsequent prolonged extraction with water.

Studies are also reported of the solubility in solutions of ammonium chlorid (concentrated), lime water, and calcium chlorid (2 per cent and tenth-normal) of the potash which occurs in what is known as soil zeolites and which is generally considered soluble in the soil solutions and available to plants. The studies were made with both unaltered rock and with rock which had been artificially enriched in potash.

The calcium chlorid solutions (either 2 per cent or tenth-normal) were found to be more active solvents than acetic acid and dissolved further amounts of lime, potash, and soda from material which had previously been completely exhausted with ammonium chlorid solution. The potash removed corresponded to that in form of zeolites.

Investigations on the insoluble alkali compounds originating in the humus substances of the soil and their rôle in plant physiology and agriculture,

Berthelot (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 10, pp. 433–445; abs. in Chem. Centbl., 1905, II, No. 17, pp. 1281, 1282*).—The author calls attention to the occurrence in living plants, soils, and composts of insoluble potash compounds which can also be prepared by the direct action of potash on artificial humic acid.

He reports studies of the composition of humic acid, artificially prepared by the treatment of sugar with concentrated hydrochloric acid, both in the fresh state and after standing several years and undergoing oxidation; of an amido acid resulting from the action of ammonia on fresh humic acid; and of humus compounds occurring in dead forest leaves, and in composts; as well as the behavior of these substances when macerated hot or in the cold with large quantities of pure water, dilute solutions of potassium chlorid, calcium chlorid, potassium acetate, and calcium acetate, and distilled with water and saline solutions (chlorids and acetates).

Artificial humic acid prepared as described has, according to the analyses reported, the following formula—$C_{18}H_{14}O_6$; and is of the nature of the lactones. When distilled with water a small amount of volatile matter similar to the acroleins is driven off. No furfurol is formed. When distilled with potassium acetate a part of the acetic acid is set free, the potash forming compounds insoluble in water. Distillation with potassium chlorid solution gave the same results as with pure water. Old oxidized humic acid gave the same results as fresh.

Treatment with dilute solutions of potassium acetate and calcium acetate resulted in the formation of insoluble compounds of these bases, while maceration or distillation with potassium chlorid or calcium chlorid produced no perceptible effect. Two days' treatment of fresh humic acid with dilute solutions of potassium chlorid and ammonia gave an almost neutral solution and a compound insoluble in cold water which contained 63.66 per cent of carbon, 4.34 per cent hydrogen, 0.98 per cent nitrogen, 3.22 per cent potash, and 27.8 per cent oxygen. Of the 11.75 parts of potash used, 3.21 parts had become insoluble and of 3.5 parts of nitrogen used 0.82 part had become insoluble.

In experiments with water and soda solution extracts of leaves and compost it was found that distillation with water and a dilute solution of potassium chlorid resulted in a neutral solution and the formation of small amounts of furfurol. Distillation with potassium acetate resulted in the formation of free acetic acid. Maceration with potassium chlorid and potassium acetate resulted in a considerable increase of insoluble potash and soluble lime, while treatment with calcium chlorid and calcium acetate increased the amount of insoluble lime, and in case of the compost reduced the amount of insoluble potash. The importance of these insoluble compounds of potash and of lime with humic acid and analogous substances from the standpoint of the processes going on in cultivated soils and from that of plant growth is discussed.

Peat and its products, W. A. Kerr (*Glasgow: Begg, Kennedy & Elder, 1905, pp. XVI + 318, pls. 25*).—"The aim of this work is to direct general attention to the economy of peat as a substitute of coal and for the development of its numerous by-products"

It contains introductory chapters defining peat and explaining its commercial importance in Great Britain. Other chapters discuss peat as an article of fuel, peat charcoal or peat coal, gas from peat, electricity from peat, how to use peat fuel, peat moss litter, peat as a manure, peat bricks and earthenware, the germ-destroying action of peat-moss litter and peat dust treated with acids, health-giving properties of peat, reclamation of bogs and moors, and how to work a peat bog. Articles on the distillation of peat, utilization of the peat bogs of Ireland for the generation and distribution of electrical energy, and state aid to industry (including "Gewerbe" museums and cottage industries) are given in appendixes.

The scattered literature of the subject is quite fully reviewed in this book and rather complete details are given of construction of machines and of processes employed in the manufacture of various products from peat.

Manurial requirements of the Cecil silt loam of Lancaster **County, S. C.**, F. D. GARDNER and F. E. BONSTEEL (*U. S. Dept. Agr., Bur. Soils Circ. 16, pp. 7*).—This circular reports results of tests by the wire-basket method of the effect on the green weight and transpiration of wheat plants (grown 20 to 25 days) of cowpeas 2½ and 5 tons; nitrate of soda, sulphate of potash, and acid phosphate 200 lbs. each, alone or in combination with one another and with lime; barnyard manure 10 tons, alone and with 1 ton of lime; and lime alone 1 ton, on Cecil silt loam from a plantation which had formerly been subjected to exhaustive culture but in recent years had been considerably improved through the raising of live stock, diversification of crops, better cultivation, and the construction of terraces and ditches to prevent destructive washing.

The particular soil used was a yellowish brown or gray mellow silt loam usually free from stone. "It contains sufficient clay to clod and bake badly if stirred in too wet condition, but if plowed in proper moisture condition it is mellow and fine. The subsoil to more than 3 ft. deep is a bright-red, massive silty clay loam or clay, crumbling readily when dry, especially in the upper portion, but becoming more plastic and tenacious in the lower."

Mechanical analyses of this type of soil are given, but no data regarding its chemical composition.

The results of the wire-basket tests show that the cowpeas and nitrate of soda were most effective in increasing the productiveness of the soil. Neither acid phosphate nor sulphate of potash gave any appreciable increase in growth.

"Thinking that there might be a residual effect from the fertilizer, certain of the treatments were replanted with wheat without repeating the fertilizers. In case of the untreated soil the second crop was reduced in yield to 65 per cent of the first, whereas the reduction in yield with a complete fertilizer either with or without lime fell to 36 per cent of the original yield which was produced with the fertilizer. In fact, the second crop in the baskets to which fertilizer had been originally applied was very slightly greater than was the second crop on the untreated soil, which shows that the effect of the commercial fertilizer was practically exhausted by the first crop. It is also worthy of mention in this connection that it is impossible even by repeating the fertilizer to secure as large a yield in the second or the third crop as was originally secured with the treatment in the first crop."

The increase of stock raising as well as the larger use of leguminous plants for green manuring are recommended as practical means of increasing the productiveness of this class of soils.

Manurial requirements of the Portsmouth sandy loam of the Darlington area, South Carolina, F. D. GARDNER and F. E. BONSTEEL (*U. S. Dept. Agr., Bur. Soils Circ. 17, pp. 10*).—The character and previous treatment of the soils of a representative plantation in this area are described and experiments with a sample of the soil by the wire-basket method to test the effect of different systems of manuring on the growth of wheat are reported. The fertilizing material used included cowpeas and lime alone and in combination, barnyard manure with and without addition of lime, and sodium nitrate, potassium sulphate, and acid phosphate in various combinations with one another and with lime.

The results show "that this soil, although thoroughly cultivated, well supplied with commercial fertilizers, and subject to a systematic rotation of crops, in which cowpeas are frequently grown, has responded in a marked degree to many of the manurial treatments. Cowpeas have produced decidedly the largest increase in growth, applications of 2½ tons and 5 tons giving increases of 57 and 104 per cent, respectively, and by supplementing this treatment with small amounts of lime, the gain has been increased to 99 and 138 per cent."

Lime alone produced very marked results, and when used in combination increased the effect not only of cowpeas, but of a complete commercial fertilizer consisting of

200 lbs. per acre each of sodium nitrate, potassium sulphate, and acid phosphate. The smaller applications of lime (1,000 lbs. per acre) gave a slightly larger increase than applications of 2,000 lbs. per acre. The lime produced nearly twice as much gain when used with a complete fertilizer as when used alone.

"Barnyard manure has given a considerable increase, but from the economical standpoint is not equal to cowpeas and lime, and, furthermore, its use is restricted for want of supply."

To test the residual effects of the various treatments a number of the baskets were replanted without further addition of fertilizing materials. The most striking feature of the results was "the marked reduction in the growth of the second crop, which is frequently less than half what it was in the first instance. The relative growth as affected by the treatments is essentially the same in both crops, but there has been a marked reduction regardless of the treatment. In only two out of eight instances has the residual effect been sufficient to exceed or equal the original growth on the untreated soil."

It is stated that the results obtained in these experiments "seem to be thoroughly in accord with the observations that have been made in the field and with the experience of the planters in Darlington County."

Liming soils (*Ann. Rpts. Bd. Agr. Del., n. ser., 3-4 (1903-4), pp. 123-128*).—A general discussion of this subject, based largely on the work of the Rhode Island Station, as summarized in Farmers' Bulletin 77 of this Department. Attention is called to the advantages of the method somewhat recently introduced of applying finely ground, freshly burned lime before it has been slaked to the soil by means of a grain drill.

On the action of the water-soluble mineral constituents of plant residues on the soil, S. Krawkow (*Jour. Landw., 53 (1905), No. 3, pp. 279-288*).—Analyses of water extracts of fine-ground oak leaves before and after passing through a marly soil showed that sulphuric acid, potash, magnesia, and phosphoric acid were freely dissolved from the leaves, the lime and silica in only small amounts, iron oxid in moderate amounts.

The soil absorbed from the leaf extract large amounts of the potash (58 per cent), phosphoric acid (69 per cent), magnesia (38 per cent), and organic substances. The latter, however, were removed by repeated washing. Silica, manganese oxid, soda, and iron oxid were not absorbed by the soil. Considerable amounts of lime and sulphuric acid were removed from the soil by the leaf extract, due to exchange of bases and the action of organic acids.

Soil inoculation.—Tubercle-forming bacteria of legumes, L. L. Lewis, J. F. Nicholson, et al. (*Oklahoma Sta. Bul. 68, pp. 30, figs. 8*).—The investigations here recorded included a series of pot experiments with sterilized soil to study (1) effect of cultivation and composition of media on the activity of the germ from the alfalfa plant; (2) nature of the organisms from the cowpea and the soy bean, and of a commercial culture; (3) cross inoculation, or the inoculation of one plant with cultures obtained from another; (4) normal distribution of the tubercle-forming bacteria of the legumes in the United States; (5) ability of the tubercle-forming bacteria to increase the nitrogen content of culture media in which they are grown; (6) methods of sending out cultures; (7) cultural characters of the tubercle-forming bacteria of the legumes.

Methods of determining nitrogen in the cultures and the results obtained in a series of analyses are also given, as well as the cultural characteristics of the tubercle-forming bacterium (*Pseudomonas radicicola*) of legumes. The results obtained are believed to justify the following conclusions:

"(1) Soil inoculation with cultures of the tubercle-forming bacteria is practicable only when other conditions are favorable for plant growth.

"(2) It is possible to grow these bacteria for at least thirty to thirty-five generations on special media without materially lessening their activity.

"(3) Some cultures examined in the laboratory purporting to be cultures from the alfalfa plant do not contain the germ from the alfalfa plant at all, but are cultures of a soil organism resembling the germ from alfalfa in some particulars.

"(4) The tubercle-forming bacteria of the legumes are easily destroyed by light, consequently inoculated seed should be kept in the dark until used.

"(5) Since some of the ordinary soil bacteria form colonies very similar to those of the tubercle-forming bacteria and also resemble them to a certain extent in being vacuolated, every culture, from which subcultures are to be made for distribution, should be tested in pot experiments."

Soil inoculation, L. L. Lewis, J. F. Nicholson, et al. (*Oklahoma Sta. Bul. 68, popular ed., pp. 9, fig. 1*).—This is a popular summary of the bulletin noted above.

The quality of commercial cultures for legumes, H. A. Harding and M. J. Prucha (*New York State Sta. Bul. 270, pp. 345–385*).—This bulletin gives the results of bacteriological examinations in the laboratory of the New York State Station, and in four other laboratories in different parts of the country, of 18 packages of the inoculating material for legumes formerly distributed in a dried condition upon cotton by this Department and put on the market by commercial concerns.

The examinations made it very evident that the packages were worthless for practical purposes, substantially identical results upon 6 of the packages being obtained in the 5 separate laboratories. "It was shown that the failure of these cultures was inherent in the method of their preparation rather than in any knavery of their producers. While these results will explain the many failures from the use of cotton cultures, they should not be understood as being opposed to the idea of treating the seed of legumes with living bacteria."

Commercial cultures for legumes not reliable, F. H. Hall, H. A. Harding, and M. J. Prucha (*New York State Sta. Bul. 270, popular ed., pp. 10, fig. 1*).—A popular summary of the above bulletin.

Soil bacteria, A. A. Brown (*Jour. Dept. Agr. Victoria, 3 (1905), No. 6, pp. 426–437, figs. 3*).—A general discussion of this subject, based largely upon Conn's treatises (E. S. R., 13, p. 623; 15, p. 74).

The micro-organisms of the soil, M. E. Kayser (*Ann. Sci. Agron., 2. ser., 10 (1905), I, No. 3, pp. 432–449*).—This is a review of investigations relating to nitrification, denitrification, and fixation of nitrogen (symbiotic and nonsymbiotic).

The nitrogen feeding of agricultural plants, Wein (*Chem. Ztg., 29 (1905), No. 80, pp. 1066, 1067*).—This is an abstract of a report before the section of agricultural chemistry of the Society of German Naturalists and Physicians at the meeting at Meran, September 24–30, 1905.

The report discussed methods of conducting field experiments with fertilizers and of interpreting the results. Summarizing the results obtained in comparative tests of nitrate of soda, ammonium sulphate, and lime nitrogen on field, garden, and forcing crops, the following conclusions are drawn:

(1) Lime nitrogen is as a rule not suited to top-dressing, but should be plowed in to a moderate depth when applied. (2) With field crops lime nitrogen is only from 75 to 90 per cent as effective as nitrate of soda; with garden crops it is as effective as nitrate of soda. (3) Sulphate of ammonia is as a rule as effective as nitrate of soda except in case of small fruits, on which it is less effective than either nitrate of soda or lime nitrogen. (4) This lower effectiveness is not believed to be due to evaporation of ammonia, since lime nitrogen suffers a greater loss in this respect than ammonium sulphate. The lower efficiency of the ammonium sulphate is believed to be due to the injurious effect of the sulphuric acid of the salt. (5) The liberal use of complete fertilizers affords a protection against frost and freezing, although

there is no evidence of any specific power of protection against frost possessed by potash fertilizers or nitrate of soda per se. (6) Forcing crops are in their early stages of growth sensitive to lime nitrogen. (7) On moor soils which contain as much as 7 per cent of free humic acids the use of lime nitrogen results in transformations which hinder the utilization of the nitrogen during the first season, followed by an increased action the second season. Moor soils which contain considerable amounts of calcium carbonate utilize the nitrogen of lime nitrogen normally the first year. (8) Lime nitrogen is not suited to the manuring of grass lands.

The report also refers to experiments carried on in cooperation with Hiltner in which inoculation of soy beans on moor soils prevented normal development.

On the loss of nitrogen in liquid manure and its prevention by means of superphosphate, H. Björn-Andersen (*Tidsskr. Landökonom., 1905, No. 3, pp. 160–168*).—The loss of nitrogen during storage can be largely avoided by the use of well-closed cisterns. The losses due to volatilization of ammonia compounds when the liquid is spread can not, however, be wholly overcome, and vary with the character of the soil, temperature, subsequent rainfall, etc.

Laboratory experiments conducted by the author showed that the loss of nitrogen may be considerably decreased through the addition of 2 per cent superphosphate, but that double this quantity is required in order to entirely prevent a loss of ammonia. The losses sustained after addition of varying amounts of superphosphate were determined by the author.—F. W. Woll.

Nitrates and nitrites as fertilizers, T. Schloesing, Jr. (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 20, pp. 745, 746*).—Attention is called to recent development in methods of preparing nitric acid from the nitrogen of the air by means of electricity, and especially to the process of Birkeland and Eyde, which promises to be of some commercial importance and to be able to furnish considerable quantities of calcium nitrate to replace the rapidly disappearing deposits of nitrate of soda.

The calcium nitrate prepared by the process referred to contains about 13 per cent of nitrogen, a part of it being in the form of nitrite. The fertilizing value of this material was compared with that of nitrate of soda and of a mixture of sodium nitrite and calcium nitrite in pot experiments with corn. The results show that the different applications were about equally effective in increasing the yield of corn.

On the use of leucite as a fertilizer, E. Monaco (*Staz. Sper. Agr. Ital., 37 (1904), No. 11–12, pp. 1031–1034; abs. in Centbl. Agr. Chem., 34 (1905), No. 10, p. 714*).—Analysis of the material experimented with showed 1.08 per cent of lime, 7.94 per cent of sodium, and 5.06 per cent of potash. When treated with ammonium nitrate, gypsum, peat, carbonated water, and spring water considerable amounts of these constituents were rendered soluble, indicating that the leucite even in freshly ground condition contains considerable amounts of assimilable plant food.

Experiments with Thomas-ammonium-phosphate lime, E. Haselhoff (*Landw. Jahrb., 34 (1905), No. 3–4, pp. 616–623, pl. 1*).—This material, which is described as a mixture of Thomas slag and ammonium sulphate mixed with siliceous powder (*Kiesilguhr*) and some oily substance such as petroleum to prevent the volatilization of ammonia, was studied with reference to stability of the ammonia compounds, and was also tested with reference to fertilizing value in pot experiments with wheat and barley on sandy loam soils.

The material used contained 5.94 per cent of total nitrogen, 5.66 per cent being soluble, 7.68 per cent of total phosphoric acid, and 28.9 per cent of lime. In closed bottles the loss of nitrogen was small even after the lapse of 1½ years, but in an open flask, porcelain dish, or linen bag the loss was very large within 4 weeks. The results show the material to be a very effective fertilizer, but its value in practice will depend upon the price at which it can be bought.

Comparative tests of Thomas slag and agricultural phosphate, Kuhnert (*Mitt. Deut. Landw. Gesell., 20 (1905), No. 42, pp. 334, 335*).—In plat tests with rye

the Thomas slag (16 per cent citric acid soluble in phosphoric acid) gave much better results during the first year than agricultural phosphate (ground crude phosphate containing 25 per cent total phosphoric acid).

Sources of supply and methods of manufacture of phosphates and potash salts, E. B. VOORHEES (*Jour. Franklin Inst., 160 (1905), No. 3, pp. 211-215*).—Brief accounts are given of the various sources of supply of natural phosphates, especially in the United States, and of the Stassfurt potash deposits. The condition of the phosphoric acid in different kinds of phosphates and their suitability for the manufacture of fertilizers are discussed, as well as the manufacture of refined potash salts from the crude salts and their use in the manufacture of fertilizers.

Experiments with various potash fertilizers, E. HASELHOFF (*Landw. Jahrb., 34 (1905), No. 3-4, pp. 647-664, pl. 1*).—An account is given of comparative pot tests of potassium chlorid, potassium sulphid, potassium phosphate, potassium nitrate, kainit, and 40 per cent potash salts, applied to potatoes followed by wheat. The potash salts were used in connection with a basal fertilizer mixture containing the necessary amounts of nitrogen and phosphoric acid. The fertilizers were applied only to the potato crop, their after-effect being observed on the wheat.

The data reported include yield and composition of the tubers and vines of the potatoes and straw and grain of the wheat, the data for composition being used especially as a basis for studying the relative rates of assimilation of potash and soda in the different parts of the plants and with the different fertilizer combinations. All of the potash fertilizers increased the yield of potatoes, but the results were not conclusive as to the relative effectiveness of the different potash salts in this respect. Two varieties of potatoes were used in the experiments, Gloria and Magnum bonum, and the results show that the relative efficiency of the fertilizers varied with the variety of the potato grown.

A partial substitution of potassium chlorid by sodium chlorid resulted in a small increase in yield, but when the amount of sodium chlorid was further increased there was a decrease in yield. There was no after-effect of the potash salts on spring wheat in one series of experiments and but a slight after-effect was observed in a second series. The after-effects of substitution of sodium chlorid for potassium chlorid were the same as with the first year's crop. The amount of potash taken up by the plants varied with the different salts. The smallest amount of potash was taken up by potatoes from the kainit, but during the following year the wheat assimilated the largest amount of potash on the plat which had received kainit the previous year.

Sodium, whether applied in the form of sodium nitrate or sodium chlorid, was taken up by both potatoes and wheat, and resulted in an increase of the sodium content of both vines and straw and tubers and grain, the increase in case of the grain being especially noticeable. The amount of soda assimilated varied with the amount applied and its relation to the amount of potash present. It appears probable that by the application of sodium chlorid or potash salts containing sodium chlorid the potash of the soil is rendered soluble and more easily assimilated by the plants.

The availability of mixed fertilizers, W. F. SUTHERST (*Chem. News, 92 (1905), No. 2395, p. 185*).—The solubility in 1 per cent citric acid of the phosphoric acid of bone and various mixtures of bone and muriate of potash, kainit, nitrate of soda, sulphate of ammonia, and salt is reported. The results show that the availability of the phosphoric acid was increased in some cases and decreased in others by mixing the bone with the chemicals.

In case of bone meal containing a considerable amount of organic matter the solubility of the phosphoric acid in 1 per cent citric acid was decreased by admixture of muriate of potash, kainit, and salt. In case of bone flour containing a small amount of organic matter the admixture of the chemicals in every case increased the

solubility of the phosphoric acid, the increase being especially marked in the case of nitrate of soda.

Inspection and analyses of commercial fertilizers on sale in the State, W. F. HAND ET AL. (*Mississippi Sta. Bul. 91, pp. 54*).—This bulletin gives tables of analyses of fertilizers inspected during the season of 1904–5, being the fourth publication of analyses of samples of fertilizers drawn during that season.

AGRICULTURAL BOTANY.

The sensitiveness of the chlorophyll of plants tolerant and intolerant to shade, W. LUBIMENKO (*Rev. Gén. Bot., 17 (1905), No. 201, pp. 381–415, pls. 2, fig. 1*).—Experiments are reported in which the author sought to establish the minimum of light intensity required for carbon dioxid decomposition by a number of species of plants.

The subjects of the experiments were Scotch pine and birch representing intolerant species, and fir and linden as those tolerant of shade. The choice of these species was made so that the results obtained with the evergreen trees would be comparable, as would also those obtained with the deciduous species. These different trees were observed under artificial conditions of light and under natural conditions of very diffused light, strong light, and full sunlight.

For the intolerant species the average results show that the energy of carbon assimilation increases with the intensity of light, while for the tolerant species there is an optimum which corresponds to the angle of inclination of the leaf surface to the sun's rays.

Summarizing his investigations the writer concludes that the curve of photosynthesis may be determined from the anatomical structure of the leaf and from specific qualities of the chloroplasts. The influence on the anatomical structure may be seen through all degrees of illumination. Of the species studied the birch and linden assimilated more carbon dioxid per unit of leaf weight than the pine and fir under conditions of average illumination. The specific qualities of the chloroplasts predominated where the illumination was very feeble or very intense. The tolerant species, linden and fir, began assimilation with much less illumination than the intolerant birch and pine. In the more intense light the assimilation of the tolerant species decreased, while for the intolerant ones it continued to increase with the illumination.

A microscopic examination of the leaves showed that the chlorophyll grains of the tolerant species were decidedly larger than those of the intolerant varieties. A spectroscopic examination of alcoholic solutions of the chlorophyll of the leaves showed important differences, the spectra and curves of absorption being almost in direct relation to the carbon dioxid decomposition. The author, in conclusion, says that the terms tolerant and intolerant should be considered with reference to the carbon dioxid decomposition of the species. The leaves of intolerant species require more light in order to compensate for their greater respiration.

The influence of sunlight and diffused light upon the leaf development of deciduous trees and shrubs, J. WIESNER (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl., 113 (1904), No. 8–9, pp. 469–494*).—In continuation of his photometric investigations, the author describes experiments with *Robinia pseudacacia*, *Amorpha fruticosa*, and *Broussonetia papyrifera* grown in full sunlight and in varying degrees of diffused light, the object being to determine the minimum of light required by these plants for the beginning of leaf development and for sustaining it throughout the growing season.

Regeneration in roots, B. NĚMEC (*Studien über die Regeneration. Berlin: Borntraeger Bros., 1905, pp. 387, figs. 180; rev. in Nature [London], 73 (1905), No. 1886, pp. 170, 171*).—This volume gives the results of investigations carried on to throw some light upon the nature of the processes of regeneration, the causes that initiate

and determine its occurrence, and the meaning of the physiological events that are associated with it.

In the investigations the tips of growing roots, especially seedlings, were injured in various ways by making incisions into the region about the apex, and the reactions were carefully examined and compared. The work suggests a number of important problems for future investigation, and contains an extended bibliography of literature relating to the subject.

The absorptive capacity of roots in the light and in the dark, E. PANTANELLI (*Landw. Jahrb., 34 (1905), No. 3-4, pp. 665-683*).—Seedlings of various plants, including *Zea mays*, were placed in the dark and also in the light to determine the influence of darkness upon the absorptive capacity of the roots.

It was found that when the seedlings were kept in the dark the roots took up absolutely less, but relatively more, salts than water, while in the light the reverse took place. When the stems and leaves alone were exposed to the light the roots absorbed more water while the salt absorption was relatively decreased, but when the roots alone were subjected to the action of light they took up more salt than water. These results are regarded as indicating that the use of mineral substances by the plant is not regulated by transpiration alone, and that the roots have the power of changing the relation of salt to water absorption according to conditions. The selective capacity of the living organism manifests itself in such cases.

A study of the injury to plants by fumes from industrial works, P. SORAUER (*Landw. Jahrb., 33 (1904), No. 4-5, pp. 585-664, pls. 4*).—The results are given of a prolonged study of the effects of fumes from industrial works, especially the effects of chlorin and hydrochloric-acid fumes, on wheat, oats, and barley.

The author describes at length the various anatomical changes observed in these different plants wherever any departure from normal structures was noted. These include changes due to ripening, injury, fungi, overfertilization, superabundant water, etc., comparisons being made with injuries attributed to noxious fumes and with the changes experimentally produced upon the plants under observation when exposed to chlorin and hydrochloric-acid fumes.

Summarizing his observations, the author says that the injuries due to fumes differ only in degree from those observed on similar plants not subjected to the influence of gases. The distinction between injured and uninjured plants is a quantitative one, and can only be determined by comparisons with similar plants grown in regions known to be free from injurious fumes.

Pot experiments to determine the limits of endurance of different farm crops for certain injurious substances, F. B. GUTHRIE and R. HELMS (*Agr. Gaz. N. S. Wales, 16 (1905), No. 9, pp. 853-860*).—Pots were filled with a rich garden loam mixed with a nearly equal quantity of light sand and fertilized with 10 gm. of superphosphate. To these pots were added different quantities of sodium chlorid, sodium carbonate, sodium chlorate, and arsenious acid, and the effect on the germination and growth of barley and rye was observed. The results obtained are shown in the following table:

Effect of different percentages of injurious substances in the soil on the germination and growth of barley and rye.

	Sodium chlorid.		Sodium carbonate.		Sodium chlorate.		Arsenious acid.	
	Barley.	Rye.	Barley.	Rye.	Barley.	Rye.	Barley.	Rye.
	P. ct.	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*
Germination affected	0.10	0.10	0.25	0.25	0.005	0.004	....	0.20
Germination prevented	.25	.40	.60	.50	.007	.006	....	....
Growth affected	.10	.15	.15	.25	.003	.002	0.05	.15
Growth prevented	.20	.20	.40	.40	.006	.004	.10	.30

The germination of barley was unaffected by 0.6 per cent of arsenious acid in the soil, while its growth was prevented by a much smaller quantity. The results also showed that it required more than 0.4 per cent of this substance in the soil to affect the germination of rye.

Albinism in the plant kingdom, E. PANTANELLI (*Ztschr. Pflanzenkrank., 15 (1905), No. 1, pp. 1-21*).—A study was made of albinism in plants, as distinguished from chlorosis, blanching, etc. The wide distribution of albino forms of foliage is commented upon and numerous examples are cited. The anatomical changes associated with this abnormal growth are described, and the various theories regarding the cause of albinism are reviewed.

The author believes that albinism is a constitutional disease of the plant, which is not infectious and which is due in the first place to a large accumulation of oxidizing enzyms. It is believed probable that the first accumulation takes place in the stems or roots of the plant, and, so far as the author's investigations go, this is not transmitted through the seed. The oxydases are distributed through definite channels to the leaves, where the chloroplasts are more or less changed and the protoplasm becomes affected, as is shown by its peculiar physical properties.

Chemical investigations show that the protoplasm and its plastids are destroyed through the great abundance of destructive enzyms. Associated with the changed condition of the chlorophyll and the cell plasma, growth is checked. The methods of dissemination and control are to be subjects of further investigation.

The effect of low temperatures on moist seeds, J. ADAMS (*Sci. Proc. Roy. Dublin Soc., n. ser., 11 (1905), No. 1, pp. 6*).—Seeds of peas, barley, flax, Swedish turnips, red clover, meadow fescue, and timothy were inclosed in a cloth and buried in moist soil for 3 days, in order that they might absorb water slowly.

These moist seeds were then divided into different lots, one of which was cooled by evaporating ether and then immersed in liquid air for 23½ hours; a second lot was immersed in liquid air for 24 hours without any preliminary cooling, and a third was inclosed in a small corked bottle and placed in liquid air for 6 hours. A fourth lot, which had not been moistened, was used for comparison.

The seeds of the first and third lots were practically destroyed, with the exception of the timothy. The lot of dry seeds and those not subjected to cooling germinated about normally. In the case of the timothy seeds the author states that they did not absorb water to any appreciable extent, and their prolonged vitality was probably due to this fact.

In discussing the phenomena related to the action of low temperatures on seeds, the author states that the injury was probably due to the withdrawal of water from the cells of the seed and its freezing in the intercellular spaces. Whenever the seeds contained less than 12 per cent of moisture the subjection to liquid air did not seem to be detrimental.

While experiments on dry seeds, spores, etc., seem to show that there is no fatal minimum temperature for dry protoplasm, the author thinks that it is fair to assume that there is a fatal minimum temperature for moist protoplasm and that this minimum is above the temperature of liquid air.

The action of liquid air on the life of seeds, P. BECQUEREL (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), No. 25, pp. 1652-1654*).—The author repeated the experiments of a number of investigators on the effect of intense cold on the life of seed, experimenting with seeds of castor bean, pine, squash, buckwheat, corn, wheat, oats, beans, lupines, peas, vetches, alfalfa, and radish.

Different lots were placed under varying conditions in liquid air, where they were kept for 130 hours at temperatures varying from −185 to −192° C. At the expiration of this time their viability was tested, and the results show that the resistance of seed to low temperatures depends on the amount of water and gas present in their

tissues. If there is sufficient water and gas present the cold disorganizes the protoplasm and nucleus, making germination impossible, but if the protoplasm by drying has reached its maximum concentration and at the same time its minimum activity, the action of low temperatures is not injurious to the seed, which still retain their germinating power.

FIELD CROPS.

Cooperative fertilizer experiments, 1904, P. Bolin (*K. Landtbr. Akad. Handl. och Tidskr., 44 (1905), Bihang, pp. 117*).—Cooperative fertilizer experiments conducted under the direction of the Royal Academy of Sweden at a large number of farms in different parts of the country are reported. In all, 280 experiments, comprising 149 with small grains, 90 with root crops, 36 with meadows, and 5 with winter grains, and aggregating 7,100 plats, were made. Earlier work in this line has been previously noted (E. S. R., 15, p. 569).

Experiments with oats on clay soils showed that the largest and most economical returns were obtained from the use of 178 lbs. of nitrate of soda, 267 lbs. of superphosphate, and 89 lbs. of 37 per cent potash salt per acre. As in the previous year, nitrate of soda was most effective, every 100 lbs. of this fertilizer giving an average increase of 300 lbs. of grain and a corresponding weight of straw. Superphosphate was of appreciable effect when applied in connection with nitrate of soda, while potash did not generally prove profitable either on clay or sandy soils. General experience teaches that oats are relatively little affected by potash fertilization. On humus and moor soils applications of 89 lbs. of nitrate of soda, alone or with 178 lbs. of superphosphate, per acre gave more satisfactory financial returns, but the highest yields were obtained where the complete application mentioned above was used. Barley on sandy or peaty soils readily responded to the use of potash.

The results also indicated that on rather heavy soils the nitrate of soda is better applied all at one time before sowing, even when as much as 178 lbs. per acre is used. The smaller application, 89 lbs. per acre, produced especially favorable results when used in this way as compared with its use as a top-dressing. On the lighter soils, however, a top-dressing of 89 lbs. per acre was completely utilized by the crop. The results again indicated that a top-dressing with nitrate of soda has a tendency to increase the yield of straw rather than that of grain as compared with applications of like amounts before sowing.

The average results for 2 years showed that 267 lbs. of nitrate of soda (half applied as a top-dressing), 267 lbs. of superphosphate, and 356 lbs. of potash salt per acre produced the heaviest yields of potatoes on sandy soils. As observed in previous experiments, the starch content stood in inverse ratio to the yield, but the largest total yield of starch per acre was obtained on the fertilized plats. The results indicated that in general potatoes grown for factory purposes are more profitable when a medium application of fertilizers is used than when heavy applications are given for the production of a maximum crop.

Mangels grown on humus soils responded most readily to phosphatic fertilizers. The heaviest yields were obtained from the use of 89 lbs. of nitrate of soda, 356 lbs. of superphosphate, and 267 lbs. of potash salt per acre.

On meadows where grasses predominated, especially on soils low in nitrogen, the most economical results were generally obtained by applications of nitrate of soda, while in fields where the stand consisted largely of clover and the soil was high in organic compounds, phosphates and potash produced the best results.

Comparisons were made of ammonium sulphate and nitrate of soda in a series of 14 experiments with roots and small grains. The heavy applications consisted of 267 lbs. of nitrate of soda per acre for roots and 178 lbs. for grain, and the light applications of 178 lbs. and 100 lbs. per acre for roots and grains, respectively. The

applications of ammonium sulphate furnished the same quantities of nitrogen. The yields obtained with the heavier applications were practically the same, while with the lighter applications of sulphate of ammonia the yield of roots was only 75 per cent of that with the nitrate of soda and of grain 67 per cent, so that on the whole nitrate of soda proved the more profitable.

Experiments with oats on a clay soil low in nitrogen indicated that calcium cyanamid, which decomposes in the soil and gives off ammonia, approximates ammonium sulphate in fertilizer value.

The average results of 9 series of experiments with oats on humus soils showed that superphosphate and Wiborgh phosphate were about equal in value, while steamed bone meal and raw bone meal were inferior to these 2 soluble phosphates.

The kernel weight of the grain crops was considerably higher on the fertilized plats than on the check plats. The average weight in 31 series of experiments of 1,000 of the kernels in the check tests was 45.22 gm. and for the plats receiving the heaviest fertilization, 47.06 gm. In 20 series of barley experiments 1,000 grains on the control plats weighed 45.01 and on the fertilized plats 46.79 gm. The lowest kernel weights were obtained with the heaviest application of phosphatic fertilizers, indicating that phosphoric acid hastens the maturity of the grain and shortens the growing period, so that a smaller amount of starch is deposited in the kernels than when a well-balanced fertilizer is applied.—F. W. WOLL.

Report of the government agrostologist and botanist for the year ending June 30, 1904, J. BURTT-DAVY (*Transvaal Dept. Agr. Ann. Rpt. 1904, pp. 261–320, pls. 21, maps 5*).—This report contains brief notes on the different field and forage crops tested during the year, and a review of observations on the stock range and native economic plants.

The author points out the wastefulness of veld burning, which is practiced all over the Transvaal for the purpose of destroying the ticks and of providing early green feed. A list of noxious weeds is given, and the more important species are discussed.

The effect of press drilling on grain crops in 1904–5, FALKE (*Deut. Landw. Presse, 32 (1905), Nos. 74, pp. 626, 627; 75, pp. 629, 630*).—Comparative and cooperative tests made with press drilling spring and winter wheat, winter rye, and winter barley resulted in every case in higher yields than those obtained from ordinary drilling, but the increase was not uniformly large.

The press-drilled plats showed a quicker and more even growth, and stronger as well as better developed plants in both fall and spring, than the plats drilled in the ordinary way. Not only did press drilling increase the yield when the precipitation was scant, but also when the rainfall was quite ample. In one test on a light soil well provided with moisture an increase of 21.9 per cent in the yield of grain was secured.

Farm grasses of the United States, W. J. SPILLMAN (*New York: Orange Judd Co.; London: Kegan Paul, Trench, Trübner & Co., Ltd., 1905, pp. XII + 248, figs. 54*).—This book is a practical treatise on the grass crop and contains directions for the seeding and management of meadows and pastures, descriptions of the best varieties of grasses and their distribution, discussions on grass seed and its impurities, a consideration of grasses for special conditions such as wet, dry, and sandy lands and alkali soils, and an outline on lawn making. Notes on commercial grades of hay and straw and rules for measuring hay in the stack are given, and the improvement of grass is discussed.

The cause of growth in barley, W. WINDISCH and K. SCHÖNEWALD (*Wchnschr. Brau., 22 (1905), No. 14; abs. in Biochem. Centbl., 4 (1905), No. 1, p. 24*).—It was found that barley sterilized by means of an alcoholic solution of corrosive sublimate germinated as readily as unsterilized barley. This work was done to test Nilson's theory that certain acid-producing bacteria found on the hulls of barley are necessary for germination.

Breeding experiments with barley, T. RAMIE (*Wchnschr. Brau.*, *22* (*1905*), *No. 13; abs. in Biochem. Centbl.*, *4* (*1905*), *No. 1, pp. 24, 25*).—Experiments were made to determine whether varieties usually grown on moist soils could be adapted to dry soils.

In order to bring about this result it is believed necessary to reduce the water requirements of the variety and to increase its capacity of using the natural water supply of the soil. The selection should be made with reference to a small surface of the plants as compared with their weight, and to a deep root system. The results obtained show that varieties may be modified to a high degree by selection in a certain direction. The quality of the grain remained practically the same, the original protein content and the size of the kernel being retained.

What influence has the chemical composition of the seed on the development, quality, and productiveness of barley, and to what extent are these characters transmitted? J. VAŇHA, O. KYAS, and J. BUKOVANSKY (*Ztschr. Landw. Versuchsw. Oesterr.*, *8* (*1905*), *No. 7, pp. 667–684*).—Pot experiments were conducted in 1904 with barleys obtained from different sources and varying in some instances in nitrogen-free extract, but containing approximately the same percentage of protein, and in other cases varying in protein but being practically the same in nitrogen-free extract. The kernels used for seed were all more than 2⅝ mm. in diameter, and the treatment of the pots was uniform in every particular throughout the experiment. Each test was repeated five times. It was observed that each pot used 32 liters of water, which corresponded to 2.461 liters per plant.

The results, which are tabulated in detail, show that where there was a high content of nitrogen-free extract, a low percentage of total protein and a high percentage of soluble protein in the seed, there was an increase in the total yield, the yield of grain, the number and weight of the stems, and the total weight of the heads and the grain. Where the nitrogen-free extract of the seed rose from 68.68 to 79.42 per cent, the total yield increased 12.76 per cent and the yield of grain 14.62 per cent, while a decrease in protein content from 15.41 to 7.17 per cent in the seed was accompanied by a gain of 13.52 per cent in total yield and of 23.86 per cent in the production of grain. This influence is accounted for by the action of the nitrogen-free extract as reserve material and the usually better developed embryo in seeds high in nitrogen-free extract. The degree of solubility of the protein is also considered a potent factor in affecting the yield.

The number of developed stems did not appear dependent upon the quantity of nitrogen-free extract in the seed but seemed to be indirectly influenced by the content of total protein. A large quantity of nitrogen-free extract in the seed showed a tendency to lengthen the stems, while the effect of the protein content, which exerted a favorable influence on the stooling of the plants, was less pronounced in this particular. With a greater stooling capacity, resulting from a low total protein and a high soluble protein content of the seed, a larger number of heads was produced, while the quantity of nitrogen-free extract apparently remained neutral in this regard. The composition of the seed did not seem to affect the proportion of hull, the composition of the endosperm, the size of the kernel, or the germination.

The authors conclude from the data obtained that nitrogen-free extract and protein content are not transmissible characters, but are controlled mainly by the quality of the soil and the supply of plant food. A difference of 10.74 per cent in nitrogen-free extract in the various seed samples was reduced to about 5 per cent in the barley produced, and the seed lowest in nitrogen-free extract showed an increase of 4 per cent while the seed highest in this constituent gave 2.29 per cent less in the product. In protein content the seed differed by 8.24 per cent, but the crops produced differed by only 1.69 per cent, and the crop from the seed richest in protein, with 15.41 per cent, stood last, with only 7.86 per cent. The seed lowest in protein showed an increase of 1.66 per cent under identical conditions of soil and growth with the other samples.

The absolute weight of the kernel, the proportion of hull, the composition of the endosperm, and the percentage of large-sized grains did not appear to be characters of regular transmission. The fineness of the hull was transmitted with much greater regularity and greater frequency than the proportion of the hull to the grain. The product from the seed samples varying in nitrogen-free extract showed a marked reduction in mealiness, but in the case of the samples differing in protein content mealiness largely increased. In every instance except one the difference in the size of the kernels in the seed samples was greatly reduced in the crops secured.

The vitality and viability of all the barleys from the various sources were much increased. Only 3 days were required for their complete sprouting and a type of Hanna barley produced on a calcareous soil gave 100 per cent in vitality and viability when 3 years old.

Varieties of barley, E. S. BEAVEN (*Reprinted from Jour. Fed. Insts. Brewing, 8 (1902), No. 5, pp. 543–600, pls. 7*).—This paper outlines the classification of the different types of barley and discusses the differences in their structure.

Experimental work with the crop, largely with reference to its malting quality, is reviewed and a list of varieties, together with data secured on the Warminster plats for several years past, is given in an appendix. Some of the work reviewed has been previously noted (E. S. R., 9, p. 436).

Experiments with corn, T. L. LYON (*Nebraska Sta. Bul. 91, pp. 35, figs. 14, map 1*).—Cooperative tests of 14 varieties of corn were made in 6 sections of the State varying in climatic conditions.

The results of these experiments, now in progress for 3 years, indicate that in the eastern part of the State Reid Yellow Dent, Hogue Yellow Dent, Nebraska White Prize, Silver Mine, Golden Cap, Golden Yellow, Golden Row, Mammoth White Pearl, and Calico have been most satisfactory, while in the middle portion Leaming, Calico, and Pride of the North, and in the western portion Pride of the North and Calico were most promising.

In studying the relation of size of ear to yield it was found that the heaviest yielding varieties produced ears of medium size, the average weight per ear of the 5 leading sorts being 0.705 lb., or considerably below the average weight per ear of all the varieties. The corn raised in the central and western part of the State produced smaller ears than the same varieties grown in the eastern part. The number of ears per bushel, as indicated by reports from experimenters, ranged from 93 to 132.

In growing 1, 2, 3, or 4 stalks per hill it was found that the yield per acre increased with the thickness of planting. The average weight of ears as well as the percentage of good ears decreased, as did also the number of ears per 100 plants and the number of suckers per 100 plants. Under favorable conditions 3 stalks per hill in rows 44 in. apart each way gave the largest yield of grain, but the conclusion drawn is that the best rate of planting varies according to the soil and season, and that therefore in Nebraska the rate of planting in the eastern part of the State should not be less than 3 kernels per hill, while in the western part on the western edge of the corn belt 2 stalks per hill are believed to be better than a larger number.

The size of ear showed a regular decrease as the rate of planting increased. The average ear from the planting containing 1 stalk per hill weighed 10.6 oz., while the average ear of the planting with 5 stalks per hill weighed only 6.6 oz. The largest number of good ears, amounting to 68 per cent, was obtained from the planting with 2 stalks per hill. In 1904 the planting of 1 stalk per hill produced 4,392 lbs. of stover per acre, the yield regularly increasing with the thickness in planting, and reaching 6,975 lbs. per acre with 5 stalks to a hill. The proportion of grain to stover was greatest with 3 stalks per hill, and this planting also produced the greatest total yield in this season.

The observations made in 1904 on the number of barren stalks as affected by planting showed that 6 per cent of the stalks planted at the rate of 1 per hill were barren,

and this rate increased with the thickness of planting and reached 27 per cent in the corn with 5 stalks per hill.

The tillering was influenced by the thickness of planting and the fertility of the soil. The number of tillers ranged from 8 per 100 plants where 4 stalks were grown in a hill, to 198 per 100 plants where only 1 stalk was grown, and on a very fertile plat 134 tillers were produced per 100 stalks, while under identical conditions on a plat of poor soil only 61 tillers per 100 were produced. In addition to these factors, there is an inherited tendency to tiller which was shown by the difference in the number of tillers produced under similar conditions by seed from different ears. When the tillers were removed from plants 20 to 25 in. high no more developed. It was also found that under favorable conditions for growth the removal of tillers reduced the yield.

Work on increasing the yields of corn by selection of plants brought out the marked differences which exist between different ears. In 1903 the yield of 82 rows planted with different ears varied from 70 to 108 bu. per acre. The 17 rows selected from this field each yielded more than 90 bu. per acre, and 6 selected ears from each one of them were planted in 1904. The season was not as good a corn year as 1903, neither was the soil as good as that used the year before, but the average yield obtained was 68.6 bu., while corn of the same variety in the same field from seed selected in the ordinary way yielded only 62 bu. per acre.

In work on the adaptation of corn to a locality, it was found that the weight of both stalk and ear was heavier in corn grown from seed secured from Iowa, but that the proportion of ear to stalk was higher in acclimated corn. The leaf area in the acclimated Nebraska corn was almost 200 sq. in. less than in the Iowa corn, but the yield of grain was greater.

Seed corn stored in a dry seed room germinated 90 per cent, as compared with 70 per cent for corn taken from the crib. Experiments on the depth of planting indicated that this should not be greater than is necessary to secure moisture for the seed.

The influence of the size of the grain and the germ of corn upon the plant, E. P. Walls (*Maryland Sta. Bul. 106, pp. 56*).—Experiments were conducted to determine the effect of the size of the kernel as shown by its weight, and of the size of the germ on the vigor of the plant.

Kernels of different weight were grown in sand containing practically no plant food in order that a difference in their growing power might be apparent. The results indicate that the heaviest grains do not necessarily have the best germinating qualities nor do they revive most quickly after moisture has been supplied succeeding a drought. When supplied with moisture, plants from the heaviest grains attained the greatest height, while plants from the highest bred seed held their vigor best under drought conditions.

It was further shown that the germinating qualities of kernels containing germs of different sizes may be equal, but that the kernels with large germs produced plants most resistant to dry weather, and that in general as the plants grow older they are likely to be larger, hardier, and more vigorous than those from smaller germed seed. It is advised to bear in mind in the selection of seed corn that there is a great difference in the individuality of plants coming from kernels from different ears, and also from kernels of the same ear; that high breeding is of more importance than weight or size of grain, and that none but large-germed kernels should be used for seed.

American cotton supply and its distribution for the year ending August 31, 1905, S. N. D. North et al. (*Bureau of the Census [U. S.] Bul. 25, pp. 15, dgms. 2*).—A summary is given showing that for the year ending August 31, 1905, the total supply of cotton was 14,455,994 bales, of which 13,318,458 bales represented the crop of 1904; 660,881 bales, the stocks on hand September 1, 1904, at ports, in

interior towns, on plantations, in mills, and in transit, and 476,655 bales of the crop of 1905 ginned to September 1.

In addition to this supply, 124,469 bales of foreign cotton were imported. The data with reference to the distribution show that 8,834,929 bales were exported; 4,278,980 bales consumed by mills, about equally divided between mills in the North and mills in the South, and that 1,305,309 bales represented the stocks on hand August 31, 1905. The domestic consumption equaled about 30 per cent and the exports about 61 per cent of the total supply for the year, leaving a surplus of about 9 per cent, including stocks in mills, at ports, in interior towns, on plantations, and in transit.

Statistical data regarding the production, commerce, and manufacture of cotton are given, and the growth of cotton production and consumption in the United States as well as the world's cotton consumption and production by countries is tabulated and discussed.

Distribution of cotton seed in 1904, H. J. WEBBER and A. J. PIETERS (*U. S. Dept. Agr., Bur. Plant Indus.* [*Circ.*], *Jan. 9, 1904, pp. 11, pls. 3*).—The distribution of cotton seed in 1904, together with the varieties distributed, is described, directions for cultivation and ginning and for growing pure seed of good quality are given, and the results desired for publication are outlined.

Thirty-seventh annual report of the Flax Supply Association for the Improvement of the Culture of Flax in Ireland (*Ann. Rpt. Flax Supply Assoc. Ireland, 37* (*1904*), *pp. 64 + 46*).—Statistics on the production, manufacture, exports, and imports of flax for different counties are given for a series of years, including 1904.

Information concerning flax grown on the Russian steppes, A. HERZOG (*Separate from Textil u. Färb. Ztg., 2* (*1904*), *No. 40, pp. 3, figs. 2*).—A microscopical and chemical study on Russian steppe-grown flax is reported.

The microscopical data include measurements of the bast cells and a comparison of anatomical data with reference to this variety and Pernauer flax. The metrical number, that is, the number of times the weight of a single dry fiber 1 km. in length is contained in 1,000 gm., is given as follows: Russian flax 2,469; Pernauer flax, fiber from the root 1,456, from the lower portion of the stem 2,198, from the middle portion 3,992, and from the upper portion 7,407.

The middle portion of the Russian flax contained 5.17 per cent of lignin, as compared with 2.36 per cent for Pernauer flax. It is pointed out that the woodiness of the fiber has an unfavorable influence on its softness, elasticity, and strength. The Russian flax was also higher in the protein content of the dry matter of the fiber.

Sets and their position in the soil as influencing the yield of potatoes, A. ANDOUARD (*Bul. Sta. Agron. Loire-Inf., 1903-4, pp. 47-50*).—Experiments made with whole and cut tubers showed that the position of the buds on the tubers and the position of the tubers in the soil did not influence the yield to any appreciable extent.

The new potato, G. BONNIER (*Fermes et Châteaux, 1* (*1905*), *No. 1, pp. 29, 30, figs. 4*).—The history of *Solanum commersonii* is reviewed and the work carried on for the improvement of the plant discussed. The aerial and underground tubers produced by the plant are described and figured. The experimental work here referred to has been previously noted (E. S. R., 17, p. 244).

Rye and some of its uses, J. M. JAMISON (*Breeder's Gaz., 48* (*1905*), *No. 14, pp. 629, 630*).—A method of growing rye and clover is described.

The rye is fall sown and pastured during the winter and in the spring the land is seeded at the rate of 1 pk. of clover seed per acre. The rye is allowed to ripen and is then harvested by turning sheep and hogs into the field. This results in a heavy volunteer crop mixed with the clover for fall pasture. The following season the clover

and the ripened volunteer crop is cut for hay. The rye straw in the clover hay has the advantage of making the stack much more capable of shedding the rain than the pure clover.

The sugar industry, and particularly the beet-sugar industry in the United States, P. DE VILMORIN (*De l'industrie du sucre et en particulier du sucre de betteraves aux États-Unis. Compiègne: H. Lefebvre, 1905, pp. 16, map 1*).—A discussion of the beet-sugar industry in the United States. The author concludes from his observations that the average yield of beets in this country is very low and the sugar content medium, except in the States where irrigation is practiced.

Sugar cane, F. S. EARLE (*Estac. Cent. Agron. Cuba Bul. 2, pp. 47, pls. 2, figs. 17*).—This bulletin is a general treatise on sugar-cane culture in Cuba, describing the various cane soils of the island, outlining different systems of growing the crop, and reporting the results of several culture and fertilizer tests.

In the prevailing system of culture the cane is planted in hills about 3 ft. apart, with a distance of 4.5 to 5 ft. between the rows The soil is prepared and cultivated the first season, but no further tillage is given. The Zayas system requires wider planting, usually 9 by 12 ft., and giving continued cultivation throughout the year with modern implements Under this system barnyard manure is used, but no commercial fertilizers are applied, and in harvesting all canes not sufficiently mature for cutting are allowed to remain for later ripening.

At the station the Zayas system failed to produce a maximum first crop as compared with the common system and the cost of production was greater. The saving of immature canes was also unsatisfactory It was further found that the cane grown by the common system ripened earlier and during November averaged about 1 per cent more of sucrose than the cane grown by the Zayas system. By the middle of December the 2 lots were practically identical, and by the end of February the Zayas cane contained 1.4 per cent more sucrose.

Results obtained by cane growers at other points also show that the Zayas system does not always give as good yields the first year as the common system. Some consider this due to injury to the roots caused by the continued cultivation. In one test the cost of soil preparation, planting, and cultivation according to this system amounted to $527.86 per caballería (about 33⅓ acres). Cane grown on red land was slightly better in quality than a crop from black land.

A new variety of spelt, P. H. STOLL (*Deut. Landw. Presse, 32 (1905), No. 59, pp. 506, 507, fig. 1*).—A new variety obtained by crossing Rivett Bearded wheat and Red Tyrolean spelt, and named Stoll Early Giant, is described.

[Bibliography of tobacco] (*Mo. Rec. Sci. Lit., 29 (1905), No. 6, pp. 186, 187*).—A list of 25 works on the culture, history, and other matters pertaining to tobacco, published from 1733 to 1897.

Spring vetch and winter vetch, E. RABATÉ (*Jour. Agr. Prat., n. ser., 10 (1905), No. 36, pp. 304–306, figs. 5*).—The 2 kinds of vetches are described and directions for their culture are given. A cultural test showed that the seeds from the same pod and the same plant are uniform in color, and it is concluded from this result that the plants are, as a rule, self-fertilized. Directions are given for the determination of the seed of the 2 species of vetches.

Experiments with winter wheat, C. G. WILLIAMS (*Ohio Sta. Bul. 165, pp. 35–65, figs. 11*).—The description of varieties grown the past 2 seasons and the comparative yields and other data of varieties tested from 6 to 12 years are presented in tabular form. The yields and protein content of the different varieties for the years 1901 to 1904, inclusive, are also given in tables.

Based on the yields of grain alone, the best 10 varieties in the order of their rank were Gypsy, Mealy, Early Ripe, Poole, Nigger, Perfection, Mediterranean, Valley, Currell Prolific, and Dawson Golden Chaff; and based on the weight per bushel, the

10 varieties testing highest were Hickman, Red Wonder, Fulcaster, Gypsy, Valley, Deitz, Currell Prolific, Perfection, Nigger, and Lebanon. Velvet Chaff, Lehigh, Sibley New Golden, Red Wonder, Lebanon, New Columbia, Fultzo-Mediterranean, Deitz, and Buda Pesth, in the order given, ranked highest in percentage of protein.

It was observed that a high temperature for the month preceding harvest quite uniformly decreased the yield and weight per bushel, but owing to a reduced starch content, increased the percentage of protein. Anything hindering the normal development of the kernel, as plant diseases or insect enemies, also increases the percentage of protein, but this increase due to these various causes is not desirable because the protein is found more largely in the bran and other products than in the flour. A high protein content in normally developed wheat is desirable and should be sought for as a variety characteristic.

Ranking the varieties on a basis of 60 points for yield, 25 for weight per bushel, and 15 for protein content, the following 10 scored highest: Gypsy, Early Ripe, Nigger, Poole, Mealy, Currell Prolific, Valley, Red Wonder, Democrat, and Fulcaster. The first 4 of these varieties are considered as quite generally satisfactory for the entire State. Mealy is described as doing well on rather thin upland, being quite disappointing on rich soils and bottom lands, and giving in general a good yield but having a greater tendency to shrivel than many varieties.

The results of 11 years' work indicate that on the somewhat worn lands of the State from 8 to 10 pk. of seed wheat per acre will give better yields than a smaller quantity. In normal seasons seeding September 20 to 22 has been most satisfactory, with seeding September 15 standing next. In only 3 seasons out of 13 did first grade seed as graded by a fanning mill give larger yields than seed from which the small and light grains had not been so removed. The removal of the shrunken, broken, and extremely small grains is advised, for the purpose of securing a more uniform seeding and a greater vitality to resist unfavorable seasons.

The selection of large as compared with small heads indicated that permanent improvement must be based upon the selection of plants as a whole, and not upon certain parts. The excellence of the plant must be due to hereditary influences rather than environment. Methods of wheat breeding by selection are given.

The annual report of the seed control station at Örebro, 1904, J. WIDÉN (*Örebro Kem. Stat. och Frökontrollanst. Årsber. 1904, pp. 27–49*).—The average results of purity and germination tests of a list of grass and field crop seeds are given in tables.

HORTICULTURE.

Report of the fruit experiment stations of Ontario, 1904, L. WOOLVERTON ET AL. (*Ann. Rpt. Fruit Expt. Stas. Ontario, 11 (1904), pp. 144, figs. 88*).—Original descriptions and half-tone illustrations are given, in continuation of previous work (E. S. R., 16, p. 264), of 13 varieties of apples grown in Ontario, 4 of blackberries, 4 of grapes, 14 of peaches, 9 of pears, 7 of plums, and 1 of quinces, with an account of the work done during the year at the various experimental fruit stations and general notes by the experimenters on the various fruits grown. In addition a list of fruits recommended for planting in various parts of the Province of Ontario is given, together with the papers presented at a meeting of the association.

British fruit growing, S. PICKERING (*Nature [London], 72 (1905), No. 1869, pp. 396, 397*).—A discussion of fruit culture in relation to meteorology, more especially frosts, with some data on the blooming period of a large number of varieties of apples in England.

It was noted at the Woburn Experimental Farm that there was an apparent connection between earliness of blooming and the earliness of ripening of the fruit. Thus, 37 early varieties were in bloom on an average, May 4.7; 40 mid-season varieties, May 6.3; and 40 late varieties, May 8.

British fruit growing, A. O. WALKER (*Nature [London], 72 (1905), No. 1867, pp. 342, 343*).—The author calls attention to the desirability of experiments being made to determine the effect of locality and climate in orchard planting. Some meteorological data are given which show the variations that occur in the same latitude at various elevations and exposures.

Fruit culture in Argentina, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 27 (1905), No. 2, pp. 192–210, figs. 6, map 1*).—An account of the climatic and soil conditions of Argentina and the production, culture, and export of fruit.

From recent statistics it appears that there are about 200,000 acres planted with fruit trees and 120,000 acres planted with vines. Of the different fruits grown, exclusive of grapes, peaches constitute 40 per cent, citrus fruits 20 per cent, figs and apples 10 per cent each, pears, quinces, and plums 5 per cent each, cherries and all other kinds of fruits, including nuts, 5 per cent. It is thus seen that the peach is the principal fruit of the country. Plums also do especially well, but apples and pears are of minor importance.

Methods of marketing fruit, with descriptions of the packages used, are given, with an account of fruit exhibitions, etc.

The fruit industry at Barbados, J. R. BOVELL (*West Indian Bul., 6 (1905), No. 2, pp. 99–108*).—An account of the efforts that are being made to establish a fruit industry between Barbados and the United Kingdom.

Bananas, mangoes, avocado pears, pomelos, and golden apples have been shipped experimentally, and the details are given of these shipments and of the prices received for the different fruits. Bananas have been very successfully shipped except in the hottest weather, and it appears that when these can be delivered in good condition in England, there is no crop at present grown in Barbados which is likely to be so profitable.

Mangoes stand next in importance, and while some shipments arrived in splendid condition, others have rotted. As soon as the right temperatures for these and avocado pears can be ascertained it is thought probable that shipments of these fruits will prove quite remunerative.

Influence of the scion on stock, A. JULIE (*Prog. Agr. et Vit (Ed. l'Est), 26 (1905), No. 40, pp. 391, 392*).—The author grafted the variety Aramon Rupestris Ganzin with Gamay d'Arcenant. Some time later a shoot came out 6 in. below the graft which had leaves like the Vinifera variety with much larger and earlier fruit than the Rupestris.

Sod-grown fruit, H. M. STRINGFELLOW (*Texas Farm and Ranch, 24 (1905), No. 33, pp. 10, 11*).—The author calls attention to the especially good keeping qualities of peaches grown in sod orchards.

He sent peaches from Texas to Richmond, Va., Rochester, N. Y., and Harrisburg, Pa., where they arrived in perfect condition without refrigeration. One shipment to Rochester, N. Y., was returned to Texas without ice. The good condition of these peaches upon reaching Texas is shown in an illustration in *Texas Farm and Ranch*, 24 (1905), No. 34, p. 10. Pears grown on sod land have also been shipped by the author in carload lots to Chicago without refrigeration and arrived there in perfect condition. He argues that much of the poor keeping quality of fruits is due to cultivation of orchards.

Stringfellow tree culture, J. C. WHITTEN (*Rural New Yorker, 64 (1905), No. 2894, p. 535*).—The author reports that fruit trees root and top pruned according to the Stringfellow method have not succeeded as well at the Missouri station as trees planted and pruned in the ordinary manner.

Peaches have been less injured by the Stringfellow method of pruning than apples, and where the trees pruned according to the Stringfellow method have lived over the first summer they have invariably developed into good trees. The author notes that some commercial growers throughout the State report excellent success in

planting and pruning according to the Stringfellow method, and others much better results by the usual method.

It is believed that the method of stub-root pruning and cutting the stock back to 12 to 18 in., according to the plan advocated by Mr. Stringfellow, has been of great service in showing that it is not necessary to retain anything like the large quantity of fibrous roots which was formerly supposed. Many large growers are now cutting back the roots of trees much more severely at planting time than heretofore.

Cause of the presence of abnormal quantities of starch in bruised apples, G. WARCOLLIER (*Compt. Rend. Acad. Sci.* [*Paris*], *141* (*1905*), *No. 8, pp. 405–408*).—When apples are bruised before ripening the starch in the bruised zone is not converted into sugar during the ripening process. The author investigated the cause of this and believes that he has proved it to be due to the action of tannin on the amylase, which prevents this diastase from transforming the starch into fermentable sugar.

The packing of peaches, F. CHARMEUX (*Jardin, 19* (*1905*), *No. 446, pp. 280, 281, figs. 5*).—Illustrations showing the packages and methods of packing peaches in the south and west of France and in Spain are given.

How fruit should be packed (*Canad. Hort., 28* (*1905*), *No. 10, pp. 375–377, fig. 1*).—A discussion is given of Pacific coast practices in packing fruit and of their application to Canadian fruit.

Cold storage for fruits and vegetables, R. STETEFELD (*Gartenflora, 54* (*1905*), *No. 9, pp. 231–245*).—A lecture on this subject in which the results of experimental work in the United States and Europe are briefly reviewed and a table given showing the best temperatures for storing a large number of fruits and vegetables and the kind of packages in which they are commonly stored in Europe.

Causes of citrus fruit decay, G. H. POWELL (*Cal. Cult., 24* (*1905*), *No. 15, pp. 344, 345*).—A preliminary account is given of the investigations which are being carried on by the Bureau of Plant Industry of this Department in cooperation with the fruit interests of California, for the control of losses from disease which occur in the handling of California citrus fruits during transportation and marketing.

Thus far it has been found that mechanical injuries to the fruit are the principal causes of decay. When the skin of an orange or lemon is broken blue mold finds access to the wound and under favorable moisture and temperature conditions develops, resulting in the decay of the fruit. An examination of hundreds of boxes in different representative orange sections of the State indicate that from 15 to 20 per cent of all fruit is made susceptible to rot by puncturing or shaving the skin with clippers when the fruit is picked.

A table made up from 9 representative experiments with oranges carefully handled in comparison with clipper-cut oranges is given, which shows that in a given time in moist air and a temperature of 70° F. the decay of fruits free from cuts averaged about 2.5 per cent, while the decay in cut fruits averaged 36.9 per cent. A wide variation was found in the percentage of decay of fruits picked by different pickers, the percentage ranging from 7 to 72 per cent. Fruits cut with long stems were also found a source of injury, as the stems puncture other fruits and thus permit the entrance of disease spores. The injury from this source, however, is estimated to be about 1 in 25 in comparison with the losses from clipper cutting.

With the present method of handling fruit in packing houses it is believed that probably not 2 per cent of the clipper-cut fruit is detected and thrown out by the graders as it passes through the machinery. A large amount of fruit has been examined in bins and boxes already packed which showed that the clipper-cut fruit from such bins and packed boxes ranged from 10 to 37 per cent.

The brush may be another source of injury to the fruit. Whether it injures the fruit mechanically or whether it inoculates the fruit already injured has not been definitely determined. It has been found, however, that decay in the same lot of

fruit may be raised or lowered from 10 to 30 per cent or more by closing or opening the same brush. The brush is always full of mold spores, and if the fruit has been clipper cut, or injured in any other way, the brush is likely to deposit disease spores in these bruised places, which will eventually develop decay.

Experiments are under way to determine the effect of delay in cooling fruit before shipping. The experiments thus far indicate that the orange can be placed in any market in the country in prime condition if it is shipped quickly after picking in a cold condition. The author is not so certain about the results where the fruit stands in a packing house several days before packing and cooling. The results of several shipments to New York indicate that the cut fruit can be shipped with not more than 5 per cent of decay if the fruit is loaded in the refrigerator car quickly after the injury has been made. If, however, the oranges are delayed several days in the packing house it is probable that no degree of cooling that could be maintained by a refrigerator car could wholly eliminate the trouble.

An experiment was made in which oranges were stored at a temperature of 32° F., immediately after picking, and after 27, 52, and 94 hours' delay, respectively. The fruit had been inoculated with the blue mold. The record of decay made 10 days after the storage in each case is as follows: Immediate storage, no decay; 27 hours delay, no decay; 52 hours delay, 15.5 per cent decay; 94 hours delay, 75.5 per cent decay. "From these data and the experience in fruit storage we have no hesitation in saying that oranges ought to be packed in the quickest possible time where they are to be shipped in warm weather under ice."

Attention is called to the decay of fruits after they have been in cold storage. Cold storage simply retards decay, and if the fruits have been inoculated with disease spores it is likely they will decay after they have been removed from the cold-storage room. The fault, however, is not with the cold storage but with the previous condition of the fruit. The gist of this same article also appears in *Pacific Rural Press* (69 (1905), No. 17, pp. 260, 261).

The newer strawberries, W. J. GREEN and F. H. BALLOU (*Ohio Sta. Bul. 166, pp. 20.*)—Descriptive notes on 50 of the newer varieties of strawberries grown at the station during the year, with a tabular account of the behavior of many of the older sorts as well.

The authors deprecate the use of the term "pedigree" strawberry plants, since those thus called are not pedigreed plants at all, while really pedigreed strawberry plants have no value above those without a pedigree. The word "pedigree" is a misnomer when applied to strawberry plants, tends to confusion in the minds of many, and leads to deception. In 1903 the "pedigreed" plants of 7 varieties were compared with plants of the same varieties obtained from a reliable grower. Five of the 7 varieties gave better yields from the common than from the so-called "pedigreed" plants.

The experiment was repeated in 1905 with very similar results.

Strawberry culture in Cuba, H. J. SQUIERS (*Mo. Consular Rpts.* [*U. S.*], *1905, No. 297, pp. 178, 179*).—Notes are given on the methods of strawberry culture followed by W. P. Ladd, an American living in Santiago de las Vegas. Chocolate land has been found better than red land for this plant as the latter appears to be too porous and dries out easily. From about three-fourths of an acre $1,000 worth of strawberries were sold, giving a net profit of $597.

Small fruits, J. F. NICHOLSON (*Oklahoma Sta. Bul. 69, pp. 20*).—Popular directions based on work at the station are given for the culture of blackberries, dewberries, raspberries, strawberries, gooseberries, and currants, with accounts of the diseases and insects affecting these different fruits, and suggestions as to means of control. Of all small fruits, blackberries and dewberries succeed the best. Raspberries are not well adapted to the climate of Oklahoma, and gooseberries and currants do not succeed.

Small fruits and grapes, C. A. KEFFER (*Tennessee Sta. Bul., Vol. XVIII, No. 2, pp. 13–21, figs. 7*).—Popular directions are given for the culture of strawberries, raspberries, blackberries, and grapes, based on the results of experimental work at the station.

The two most frost-resistant varieties of strawberries out of 50 tested appear to be Michel Early and Carrie. Excelsior, Klondike, Pride of Cumberland, Clyde, Haverland, and Bubach No. 5 were all badly damaged by frost.

Especially good results have been obtained with raspberries by mulching. The mulch as applied was 18 in. deep and by spring had settled down to about 10 in. deep, and extended a foot or more on either side of the row. Raspberries thus treated were much less injured by the cold than unmulched vines, and made over twice the growth of the unmulched plants during the following season. The plants mulched with field bean straw made a better growth than those mulched with lawn rakings.

With grapes, it was noticed that the severe frost which destroyed all the new shoots in the vineyard after they were 4 to 10 in. long resulted in the production of a large amount of "blind" shoots—that is, shoots which bore no fruit. The amount of fruitful and blind wood on a number of vines of 6 varieties counted is tabulated.

Layering grafted vines; grafting cuttings by approach, F. CHARMEUX (*Jardin, 19 (1905), No. 436, pp. 120, 121, figs. 4*).—Layered shoots of European varieties of grapes throw out roots which are not resistant to phylloxera.

The method of Petit-Roch of grafting these layers by approach on either a rooted or nonrooted phylloxera resistant cutting is described. In the case of nonrooted cuttings after the graft is made the lower portion of the cutting is placed in a bottle of water. With rooted cuttings the graft is tied with raffia and otherwise treated like an ordinary layered vine, being well mounded up with earth.

The packing of hothouse grapes, F. CHARMEUX (*Jardin, 19 (1905), No. 445, pp. 260, 261, figs. 6*).—The packages used for packing hothouse grapes and methods of packing are illustrated and described.

Proceedings of the Society for Horticultural Science (*Proc. Soc. Hort. Sci., 1903–4, pp. 108*).—This publication of the society contains the papers presented before it at its two annual meetings in 1903 and 1904, a summary of which has been noted elsewhere (E. S. R., 15, p. 538; 16, p. 729). In addition it contains the constitution of the society, a list of members, officers, etc.

Okra: Its culture and uses, W. R. BEATTIE (*U. S. Dept. Agr., Farmers' Bul. 232, pp. 16, figs. 8*).—The purpose of this bulletin is to encourage a more general distribution and use of okra or gumbo (*Hibiscus esculentus*) by giving cultural hints, descriptions of a few of the leading varieties, and directions as to cooking.

Hop sprouts as vegetables, G. W. ROOSEVELT (*Mo. Consular Rpts. [U. S.], 1905, No. 297, p. 59*).—The author states that young hop sprouts are extensively used in Brussels as early spring vegetables. The most succulent sprouts are those taken from the foot of the hop plant which has been covered with earth during the winter months.

Pickles—how to make them, R. BLANCHE MADDOCK (*Canad. Hort., 28 (1905), No. 10, pp. 379–381*).—Directions are given for making cucumber, mustard, and green tomato pickles, pickled fruits, and for keeping ripe tomatoes over winter.

Ginseng in China, F. D. CLOUD (*Mo. Consular Rpts. [U. S.], 1905, No. 297, pp. 135–137*).—Brief descriptions are given of 5 sorts of ginseng found in Chinese markets, with the statement that American ginseng is liked in some Chinese cities, while in others the Chinese do not care for it and scarcely buy it at all.

Culture of mushroom spawn from spores, J. STEINERT (*Wiener Illus. Gart. Ztg., 30 (1905), No. 7, pp. 230–232*).—The author describes a successful method adopted by himself for growing mushroom spawn and gives the results of trials in growing mushrooms from such spawn.

Suggestions about seed growing, J. JEANNIN, Jr. (*Rural New Yorker, 64* (*1905*), *No. 2906, p. 725*).—Suggestions are given for selecting seed of beans, corn, cucumbers, eggplant, lettuce, melons, squashes, peas, radishes, spinach, tomatoes, celery, cabbage, and onions.

Culture and distillation of perfumery plants in Java, P. SERRE (*Agr. Prat. Pays Chauds, 5* (*1905*), *No. 30, pp. 255–258*).—This article deals primarily with the distillation of Citronella from *Andropogon citratus* or lemon grass.

Tea culture in Japan, PHIPPS (*Diplo. and Cons. Rpts.* [*London*], *Misc. Ser., 1905, No. 637, pp. 13*).—A detailed account is given of Japanese methods of curing tea, with statistics of the principal tea-producing prefectures and of the amount and value of tea produced during the year 1903. The total yield was 55,588,030 lbs.

Cultivation of tea in the Caucasus, P. STEVENS (*Diplo. and Cons. Rpts.* [*London*], *Misc. Ser., 1905, No. 628, pp. 5*).—An account of the culture of tea along the Black Sea near Batoum. The tea crop of 1903 in this region was 38,700 lbs.

Yerba-mate culture in New Germany, Paraguay, R. VON FISCHER (*Tropenpflanzer, 9* (*1905*), *No. 9, pp. 495–505*).—An account of the culture of this tea plant in Paraguay with considerable data on cost of growing a plantation, yield, etc.

Chart of flowering trees and shrubs, F. DUNCAN (*Country Calendar, 1* (*1905*), *No. 6, pp. 564–566*).—A chart is given, showing the common and botanical name, time of blossoming, color of blooms, soil, and culture requirements of a large number of ornamental trees and shrubs, arranged with reference to spring, summer, and autumn blooming. Similar data are given for trees and shrubs having brightly-colored bark for winter effect and trees and shrubs for winter fruiting effects.

Tree subirrigation along streets and parks, C. ERWIEN (*Wiener Illus. Gart. Ztg., 30* (*1905*), *No. 2, pp. 61–66, figs. 3*).—A method of watering trees along streets by means of subirrigation is described.

Iron pipes are laid 10 to 16 in. beneath the level of the street and 3 to 6 ft. from the trees. Water escapes from these through openings on the upper side. The pipes are laid in gravel with a brick over the top to prevent the entrance of dirt. The pipes must be so arranged that all the water can be withdrawn from them during the winter months to prevent freezing. Illustrations are given of the appearance of trees along streets thus watered and of other trees surface watered, which show the much greater benefit derived from subirrigation.

The book of garden furniture, C. THONGER (*London and New York: John Lane, 1903, pp. XII+100, pls. 24, figs. 11*).—In this popular book such subjects are considered as garden seats, summerhouses, archways and trellises, pergolas, gates, fences, sundials and statuary, bridges, fountains, urns, vases, etc. This is Volume 22 of the Handbooks of Practical Gardening, edited by H. Roberts.

The book of the carnation, R. P. BROTHERSTON (*London and New York: John Lane, 1904, pp. XII+95, pls. 17*).—This is a popular book on this subject, giving the history of the carnation and directions for the culture of carnations in the garden, in pots, and for exhibition. The book contains a chapter on raising new carnations by M. R. Smith. This is Volume 23 of the series of Handbooks of Practical Gardening, edited by H. Roberts.

Grafting the carnation on Saponaria, G. POIRAULT (*Jardin, 19* (*1905*), *No. 441, p. 201*).—The author grafted carnations on Saponaria for the purpose of preventing the disease caused by *Fusarium dianthi*, and describes his method of work.

Two-year-old carnation plants grown in pots are used for root grafting, preferably by the English method. Saponaria grown either in pots or out-of-doors may be used. After the graft has been made the plants are repotted and placed under bell jars in a hotbed, where they remain for 3 or 4 weeks, at the end of which time they are gradually hardened off.

Plants thus grafted flowered in December. They ceased flowering in January and February, during the resting period of the stock, and began flowering again in Feb-

ruary and March. The flowers of the grafted plants have been as large and as beautiful as those of carnations on their own roots. In this work observations will be made to determine whether the immunity acquired by grafting on Saponaria is inherited in the seedlings.

All the species of phlox worth cultivating, L. BARRON (*Gard. Mag.* [*N. Y.*], *2* (*1905*), *No. 4, pp. 167–169, figs. 10*).—The different species of phlox most commonly cultivated are described and a key given for their identification. Methods of cultivating each of the different species are included.

The incomparable Japanese lilies, W. MILLER (*Gard. Mag.* [*N. Y.*], *2* (*1905*), *No. 4, pp. 174–177, figs. 8*).—The various species of Japanese lilies that can be cultivated in this country are described, cultural methods suggested, and a key given for their identification.

A planting chart of bulbs and perennials, R. CAMERON (*Country Calendar, 1* (*1905*), *No. 6, pp. 562, 563*).—A chart is given showing in tabular form the common and botanical names, color of bloom, soil, and cultural requirements of bulbs and of herbaceous perennials blooming at different periods of the season from May to October.

Experimental researches on the seed of orchids, A. MAUMENÉ (*Jardin, 19* (*1905*), *No. 438, pp. 156, 157, figs. 4*).—This is largely a review of the work of N. Bernard, who showed that the presence of endophytous fungi in the embryo of the seed of orchids is an essential condition to their germination.

The hybridization of Odontoglossum, L. DUVAL (*Jardin, 19* (*1905*), *No. 443, pp. 238, 239*).—Methods of hybridization are described and some results secured noted.

FORESTRY.

Influence of the origin of seed on the character of forest growth, A. ENGLER (*Mitt. Schweiz. Centralanst. Forstl. Versuchsw., 8* (*1905*), *No. 2, pp. IV + 81–236, pls. 13, dgms. 2*).—Different kinds of forest seeds were gathered in localities of varying altitudes above sea level, and studied as regards weight, ability to germinate, and character of seedlings produced. The details are given in extended tables and discussed at length.

Some of the more important conclusions relative to the different kinds of seed are as follows: The weight of spruce seeds and their ability to germinate decrease in general with the height above sea level at which they are harvested. There is no decided influence, however, up to 1,200 to 1,400 meters. Seeds from high mountainous districts do not germinate with as great energy as seed from lowlands and lose their ability to germinate sooner.

The growth characteristics of highland and lowland spruce are inherited by the seedlings, even when grown under different climatic conditions. Spruce grown from lowland seed decreases in height growth with the distance above sea level and at a more rapid rate than spruce grown from highland seed. High Alpine spruce is characterized by a relatively large root development as compared with lowland spruce. Seed from green cones produces the same kind of seedlings as seed from red cones grown in the same locality. Large seed produces larger, heavier seedlings than small seed.

Seed from Alpine regions when grown in lowlands produce trees which start into growth earlier in the spring, do not grow so high, and stop growing earlier each season than trees grown from lowland seed. Seedling spruces from highland seed are characterized by closer and shorter needles than those of lowland seedlings. The structure of the needles to prevent drying out is also better. They suffer less in high situations from early frosts, from destruction of the chlorophyll by too strong insolation, and from breaking down by snow.

For restocking mountainous regions with spruce seedlings no seed grown at an altitude of 1,500 to 1,800 meters above sea level should be used. Seeds from ill-formed trees produce as good seedlings as from well-formed trees. Seeds from an especially bushy spruce produced seedlings, 67 per cent of which were like the mother tree.

In experiments with silver fir (*Abies pectinata*) all seed gathered at 1,300 to 1,400 meters above sea level proved of like character as regards weight, ability to germinate, etc.

Experiments with European larch (*Larix europæa*) showed, as with spruce, that two climatic races can be distinguished in Alpine districts. Up to 1,700 meters above sea level a quick growing kind obtains, while above this height a much slower growing variety is found, and these characteristics are inherited by the seedlings. Seed gathered up to about 1,700 meters possesses like weight and ability to germinate. Seed gathered in very high districts possesses less ability to germinate. Seed selected from trees stunted because of unsuitable soil conditions may transmit these characteristics. Therefore, in practice, only seed from well-formed trees should be gathered.

With the sycamore maple (*Acer pseudoplatanus*) also the best results are secured by planting the seed harvested in the same or like locality as regards altitude and climate.

On the whole the experiments indicate very clearly that in forestry practice the best seeds are those which are grown in the locality where they are to be planted.

A working plan for forest lands in Berkeley County, South Carolina, C. S. Chapman (*U. S. Dept. Agr., Bur. Forestry Bul. 56, pp. 62, pls. 4, map 1*).—Part 1 of this bulletin contains a general description of a tract of 44,943 acres of timber land owned by the E. P. Burton Lumber Company, with volume and yield tables, and a general account of lumbering, marketing, and transportation and grazing. Sylvical descriptions are also given of the most important trees, including loblolly pine, shortleaf pine, cypress, red and black gum, etc.

Part 2 discusses the management of this tract on the basis of these data. The investigations led to the conclusion that the prevailing species (loblolly pine), method of logging, and the location of the tract are all adapted to make the pine lands permanently valuable, if treated in such way as to insure future crops of timber. A working plan prepared with this end in view is given.

Reafforestation in the Deccan and other dry districts, H. F. Arbuthnot (*Indian Forester, 31 (1905), No. 4, pp. 205–207*).—The average rainfall of the district under discussion is under 20 in. annually, all of which falls between the second week of June and the middle or end of October. During the 7 months in which no rain falls trees planted in the ordinary way must be watered.

The author states that the ryots have developed a system of planting without irrigation which is very successful. They make ridges 2 ft. high by scraping up the surface of the soil. On the top of these ridges Neem (*Melia azadirachta*) hedges are planted. In 1 hedge 2 years old saplings were 7 to 8 ft. high and 8 to 19 in. in girth. The author planted Acha (*Hardwickia binata*) seed in the same manner and found that it made a much more satisfactory growth than when planted in an 18 in. cube pit and regularly watered from July 1.

The seasons and growth, Heck (*Forstw. Centbl., 27 (1905), No. 6, pp. 293–300*).—Some data are given on the growth of beech and ash during different periods of the year, and also on the relation of temperature and rainfall to growth during the different months.

In 1904, 57.6 per cent of the growth of ash was made by May, 32.9 per cent during June, and 9.5 per cent during July and the remainder of the summer and autumn months. With beech about 40 per cent of the growth was completed by June 1, 40 per cent more during June, and 20 per cent during the remainder of the year.

Annual rings of tree growth, E. E. BOGUE (*Mo. Weather Rev., 33 (1905), No. 6, pp. 250, 251*).—The author reports an investigation of the seasonal and annual rapidity of growth of trees at Stillwater, Okla., between October 1, 1898, and September, 1901.

Twenty-seven trees were under observation during the entire time. Among them were maples and various fruit trees, such as the plum, peach, cherry, apple, quince, pear, Russian mulberry, and apricot. The increase in girth is shown in tabular form, together with the rainfall by months, from which it appears that the month of maximum rainfall was also the month of maximum growth. It is concluded that in general there is a direct relation between precipitation and tree growth.

The use of commercial fertilizers in forestry, F. GIERSBERG (*Forstw. Centbl., 27 (1905), No. 1, pp. 31–38*).—An account of forestry experiments in Belgium with commercial fertilizers, a more detailed record of which is to appear later in pamphlet form. On poor soils the use of fertilizers has been found especially helpful. A number of examples are cited, one of which will serve to show the general trend of all.

A forest area in 1893 was fertilized with 2,000 kg. of Thomas slag and 1,000 kg. of kainit per hectare and planted. Nine years later the trees in this area had an average height of 3.1 meters, while in an area alongside which had been 10 years planted the average height was but 1.8 meters. The results of fertilizer experiments throughout Belgium the past 15 years have thoroughly established the use of commercial fertilizers in forestry work, results being obtained in 20 years with fertilizers which are hardly obtained in 30 years without their use.

Besides the more rapid growth of the trees on the fertilized areas they appear much less subject to attacks from insects and diseases than trees not fertilized, and in transplanting, even in unfavorable weather, they are much more likely fo live.

Report of the conservator of forests, C. E. LEGAT (*Transvaal Dept. Agr. Ann. Rpt. 1904, pp. 321–344, pl. 1*).—An outline is given of the work of the year, including an account of the government nurseries in different localities, timber imported into the Transvaal, seed distribution, etc.

The natural evergreen forest of the Transvaal does not exceed in area 150,000 acres. All but the most inaccessible portions of this forest has been heavily worked in past years. A list is given of the species actually found in the indigenous forests up to date.

A sylvicultural study of larch, A. CIESLAR (*Separate from Zentbl. Gesam. Forstw., 30 (1904), No. 1, pp. 27*).—An account of the natural geographical distribution of the Alpine and Siberian larches, of the larch canker, and of the culture of larch in mixed forests.

As showing the injurious effect of shade on the devolopment of larch seedlings, the author notes an experiment in which seedlings of larch, spruce, and black and white pine were grown under lath shade and without shade. Counting the volume growth of the larch seedlings in the open 100, the growth of the spruce under shade was 54, black pine 27, white pine 19, and larch 13. When spruce and larch are grown together the spruce develops slowly for a number of years, while the larch shoots up rapidly. So long as the larch is dominant the two thrive together, but in from 20 to 40 years, when the spruce overtakes the larch, the latter soon succumbs.

Much better results are obtained as regards larch when it is grown with white pine, since the white pine does not become dominant until the larch has reached merchantable size. The larch also does well with red beech.

Treatment of Scotch pine in the vicinity of Paris, L. PARDÉ (*Rev. Eaux et Forêt, 44 (1905), Nos. 5, pp. 129–143; 6, pp. 161–173*).—A discussion of the common method of growing Scotch pine (*Pinus sylvestris*) in the region about Paris.

Fifty to 60 year rotations are advocated for this tree around Paris instead of longer periods. Artificial regeneration is perhaps more satisfactory, on the whole, than natural restocking. Seed from trees 50 years old was found as valuable as seed from trees 85 years old from the standpoint of percentage of germination.

Note on the germination of teak and other seeds, R. S. PEARSON (*Indian Forester, 31 (1905), No. 3, pp. 168-171*).—Of several different methods tested for the germination of teak seeds the most successful was that in which the seed was stratified about 1 in. thick in a pit 10 ft. square and 18 in. to 2 ft. deep, with alternate layers of earth of the same thickness.

After the pit was thus filled level with the ground it was flooded with water every other day 5 times. The whole mass was then thoroughly mixed and again watered, on alternate days until the seed showed signs of germination. Suggestions are given for germinating the seeds of a number of other Indian trees.

Girdling of miscellaneous trees in sal forests, F. F. R. CHANNER (*Indian Forester, 31 (1905), No. 7, pp. 376-378*).—Of 27 species of trees girdled, it was found that 12 do not die when girdled, 5 die when well girdled, while further information is required before stating positively whether the remainder do or do not die as a result of girdling.

Some facts about gutta-percha, A. M. B. MURDOCK (*Indian Forester, 31 (1905); No. 6, pp. 309-320, pls. 4*).—An account of the species and distribution of gutta-percha in the Federated Malay States, measures observed for the protection of the tree, methods of extracting latex, manufacture, adulteration, and the properties of gutta-percha.

Coagulation of the latex of Ficus elastica, E. S. CARR (*Indian Forester, 31 (1905), No. 6, pp. 335-337*).—The methods observed in tapping *Ficus elastica* and preparing the rubber therefrom in the government plantations of Charduar and Kulsi, in Assam, are noted.

In tapping, the cuts are made at nearly right angles to the line of growth of the stem, aerial root, or branch at about 1.5 ft. apart around half of the portion tapped. The cut is made only to the cambium layer. The overflow from the cuts is allowed to fall on mats made of thin strips of bamboo woven together. This drip rubber forms a kind of a skin over the mat and has a whitish appearance, whereas that which remains in the cuts has a reddish-brown color. The former, after drying, brings a slightly lower price in the market than that collected in the cuts.

DISEASES OF PLANTS.

The fourteenth annual report of the special committee for plant protection, 1904, P. SORAUER, L. REH, ET AL. (*Arb. Deut. Landw. Gesell., 1905, No. 107, pp. LX+294*).—A report is given of the observations of the different members of the special committee on the investigation of plant diseases and plant protection, the notes being arranged topically according to host plants.

The principal groupings are diseases of cereals, beets, potatoes, leguminous plants, vegetables, and fruit trees, and vine diseases. In addition to descriptions of the fungi attacking these different plants, notes are given on insect enemies. In conclusion, a summary is given of the more practical methods for combating these fungus and insect pests.

Disease resistance of potatoes, L. R. JONES (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 87, pp. 39*).—On account of the increased interest in the possibility of disease resistance on the part of varieties of potatoes, the author was commissioned to inquire into the subject both in this country and in Europe.

The bulletin aims to present in a concise form what is known about disease resistance of potatoes. For the most part plant breeding with potatoes has been for resistance to the late blight, and this will continue to be the principal problem for some time, but there is promise of success in securing new varieties resistant to scab, dry-rot, bacterial blight, and other diseases. The author states that apparently scab diseases of tubers in Europe differ from those in this country, and certain varieties are known to be more resistant than others.

A potato disease known as blackleg, of bacterial origin, is prevalent in Europe, but is not as yet known to occur in this country, and while varietal resistance to this disease is not fully established, it seems that certain thick-skinned varieties rich in starch are more resistant than the thin-skinned ones with a low starch content.

The late blight, or rot, due to *Phytophthora infestans* occurs more commonly in Europe than in America, and the principal investigations have been on the resistance to this disease. It seems from the information at hand that disease resistance is a relative characteristic, no variety being wholly proof against the blight or rot. It seems to be related to the general vegetative vigor of the plant, and in some instances resistance may be acquired by originating new varieties, but all seedlings will not show superior disease resistance.

It is believed that some of the wild species of tuber-bearing Solanums offer promise for hybridization, but as yet no practical results have been secured. The possibility of disease resistance being established by selection has not been proved, and it is said that early varieties may escape the disease by maturing before it becomes epidemic, but when similarly exposed they are as a class less resistant than late varieties. The source from which seed tubers is obtained is said to be a matter of importance, northern-grown seed giving plants of superior resistance in Europe, and possibly tubers are better for seed purposes if they are dug before they reach full maturity. High fertilization, especially with nitrogenous manures, lowers the power of the plant to resist blight and rot, and red varieties with thick, rough skin and relatively high starch content are usually more resistant than the thin-skinned white varieties, which are richer in protein.

So far as stem and foliage characters are concerned, the evidence favors varieties that have hard, rough, woody stems and small, rough, dark-colored leaves. In England the Evergood, Discovery, Royal Kidney, Northern Star, Sir John Llewelyn, King Edward VII, Eldorado, and Factor are rated high as to disease resistance, while in Germany and Holland the best types are Mohort, Irene, Geheimrat Thiel, Professor Wohltmann, Boneza, Eigenheimer, and Paul Krüger.

In this country trials as to disease resistance have been carried on at a number of the experiment stations, notably at the Vermont Station, where breeding and selection experiments for increased resistance are under way. In this country no variety seems especially preeminent in resistance, but Dakota Red, Rustproof, Irish Cobbler, Sir Walter Raleigh, Doe Pride, and White Beauty deserve mention as of the resistant class.

The evidence at hand seems to justify the hope that by the coordinated efforts of potato specialists it will be possible to develop varieties of potatoes combining general excellence with a high degree of resistance, and the author urges all interested to aid toward the accomplishment of this end.

Club root disease of swedes and turnips, D. A. GILCHRIST (*County Northumb., Ed. Com., Bul. 3, pp. 23-42, figs. 3*).—A description is given of club root of cruciferous plants and a record presented of experiments which have been carried on to test the effect of different dressings to check the disease. A short account of the fungus which causes the disease is also given.

In the experiments for the control of the disease varying amounts of lime were employed at different dates, and on the whole it was found that the application of lime to be most efficient should be made a considerable time in advance of the sowing of the crop. In some of the plats the best results were obtained where from 1½ to 2½ tons of lime were applied 2 years before seeding. In the most extended series of experiments, which covered several years' observations, the best results were obtained where 1½ tons of lime per acre were applied to all the plats 4 years before seeding. This treatment resulted in a considerably increased total yield and a greater freedom from disease.

A disease of artichokes, F. PARISOT (*Jour. Agr. Prat., n. ser., 10 (1905), No. 38, pp. 369–371*).—A disease of Jerusalem artichokes caused by the fungus *Sclerotinia libertiana* is described.

The disease is characterized by the appearance on the lower part of the stalks of brownish spots, which, as they become older, assume a tawny color. These spots frequently arise on the lower roots and also on the tubers, but are seldom observed more than 20 or 30 cm. above the soil. At the time of the development of these spots the plant becomes dried out, taking a brownish color, the leaves wilt, and falling from the plants become rapidly disintegrated on the ground, and the roots and tubers likewise rot rapidly.

For the prevention of this disease various methods have been suggested, but probably the most efficient is that of rotation so that artichokes will not occupy the same ground oftener than once in 3 or 4 years. The same fungus is known to attack potatoes, beans, corn, carrots, beets, ruta-bagas, sunflowers, and hemp, and these crops should not be used in any rotation where an attempt is made to get rid of the fungus.

Some diseases of cotton, G. VERT (*Bol. Agr. [São Paulo], 6. ser., 1905, No. 4, pp. 156–165, figs. 8*).—Notes are given on the fungus and insect enemies of cotton, principal attention being paid to the anthracnose caused by *Colletotrichum gossypii*. This disease is described at considerable length, the information being largely based on the publications of this Department.

Spraying for cucumber and melon diseases, W. A. ORTON (*U. S. Dept. Agr., Farmers' Bul. 231, pp. 24, figs. 8*).—The purpose of this bulletin is to describe briefly the common diseases of cucurbits and the practical requirements for their control. Among the diseases described are the downy mildew, leaf blight, anthracnose, a number of miscellaneous leaf diseases, bacterial wilt, and fusarium wilt.

The author briefly summarizes experiments carried on at a number of experiment stations on the control of cucurbit diseases, and gives the results of spraying experiments made under his direction at Charleston, S. C., in cooperation with the South Carolina Station. Directions for spraying are given in detail. The author's investigations showed that at a cost of $6.22 per acre 6 applications could be given cucumbers during a season. The experiments at Charleston resulted in the production of 150 baskets per acre, which were worth at market rates about $115. This was practically entire gain, as on account of the severity of the disease the plants would have been destroyed if they had not been sprayed.

Notes are given on the control of downy mildew, powdery mildew, and anthracnose, which sometimes attack cucumbers grown under glass.

Diseases of plants cultivated under glass, L. MANGIN (*Rev. Hort. [Paris], 77 (1905), No. 17, p. 414*).—In order to combat the principal diseases of plants grown under glass, the author recommends the sterilization of the soil by heat or steam and spraying the plants with copper fungicides or naphthol.

The copper has the disadvantage of staining the plants, and this may be avoided by the substitution of naphthol for the other fungicides. Naphthol in the proportion of 1 part to 10,000 is sufficient to prevent the germination of the spores of mildew and drop disease, the two principal diseases of plants grown under glass. The use of lysol in the proportion of 5 parts to 10,000 does not prevent the germination of the spores of these fungi.

Concerning the gummosis of oranges, A. L. HERRERA (*Com. Par. Agr. [Mexico], Circ. 19, pp. 4, fig. 1*).—A description is given of the foot rot or gummosis of oranges, which has become a serious disease in Michoacán.

The disease, according to the author, is probably due to the fungus *Fusisporium limonii*, and all species of citrus fruit seem to be subject to its attack. As a treatment the author recommends the removal of the soil for a distance of a meter about the trunk, exposing the upper roots. The roots may be treated with solutions of sulphurous

acid, carbolic acid, etc. Trees should not be planted in too heavy shade, and care should be exercised in the use of nitrogenous fertilizers. Attention should be paid that the roots should not be injured during the cultivation of the soil, and where trees are dead replanting should not be made in the same location.

Leaf curl and plum pockets, P. PASSY (*Rev. Hort.* [*Paris*], *77* (*1905*), *No. 14, pp. 340, 341, figs. 5*).—Illustrated descriptions are given of leaf curl, caused by *Exoascus deformans*, and plum pockets, due to *Exoascus* [*Taphrina*] *pruni*. For the prevention of these diseases it is recommended that the affected leaves and fruits be destroyed and the trees thoroughly sprayed late in winter with a rather strong solution of copper sulphate.

Notes for the recognition of the principal diseases of the grape, G. BERTONI (*Coltivatore, 51* (*1905*), *No. 29, pp. 73–76*).—Brief directions are given for the recognition of the principal diseases of the grape, the different diseases being grouped according to the part of the plant affected.

Grape anthracnose, E. ZACHAREWICZ (*Rev. Vit., 24* (*1905*), *No. 605, pp. 76, 77*).—For the prevention of anthracnose of the grape, the author recommends a winter treatment in which the vines should be thoroughly washed or sprayed with a solution of 10 kg. sulphuric acid in 100 liters of water. This should be applied during the dormant period of the vines, and should be followed during the growing season by 2 or 3 treatments of the foliage at 10-day intervals with powdered lime 50 kg., cement 25 kg., and mineral superphosphate 25 kg.

The treatment of Botrytis on grapes, P. DE LA BATHIE (*Rev. Vit., 24* (*1905*), *No. 604, pp. 37–39*).—A report is given of experiments in which a large number of fungicides, both in liquid and powdered form, were tested for the prevention of the gray rot of grapes, caused by *Botrytis cinerea*. In addition comparisons were made of the effect of removing the leaves and of reducing the amount of nitrogenous fertilizers in proportion to the phosphatic ones used in the vineyards.

In all, 6 forms of powder and about one dozen liquids were tested. The results of the treatments showed that in a season unfavorable to the development of this disease no treatment seemed to show any material reduction in the disease from that observed in the check plats. It is believed, however, that if the season had been a rainy one some of the fungicides would have shown a marked influence in the reduction of disease. Modifying the formulas of fertilizers in general use would probably have an effect on the reduction of the disease, and shallow cultivation is recommended to replace deep cultivation, which brings about too great nitrification in the soil.

Treatments for the prevention of powdery mildew, M. CERCELET (*Rev. Vit., 23* (*1905*), *No. 592. pp. 443–445*).—The author recommends washing grapevines with a mixture of water 100 liters, sulphuric acid 5 liters, and sodium hyposulphite 1 kg.

This should be applied to the vines between December 1 and February 1, or an application of a 10 per cent solution of sulphuric acid may be used. This should be followed during the season with other treatments, for the first of which is recommended a mixture of copper sulphate 1.5 kg., sublimed sulphur 2 kg., lime 0.75 kg., and water. For later treatments the quantity of copper and sublimed sulphur is increased about 50 per cent. These proportions will make about 1 hectoliter of fungicide.

Powdery mildew and Uncinula spiralis, P. PACOTTET (*Rev. Vit., 23* (*1905*), *No. 601, pp. 681–685, figs. 3*).—A description is given of the conidial form of the powdery mildew and its relation to the perfect form, *Uncinula spiralis*. The life history of the conidial form is described at length and notes given on its distribution in France, methods of control, etc.

The black rot, F. VASSILLIÈRE (*Rev. Vit., 24* (*1905*), *No. 605, pp. 65–70*).—An account is given of the appearance, distribution, and periodicity of attacks of black rot in France.

This disease was first observed at Ganges in 1885 and quickly spread throughout other portions of France. For combating the disease the thorough use of Bordeaux mixture is advised, the applications to be made with reference to the periods of fungus invasion.

Invasions of black rot in 1904, J. CAPUS (*Rev. Vit., 23 (1905), Nos. 594, pp. 485–489; 595, pp. 523–528; 596, pp. 549–552; 597, pp. 574–577, fig. 1*).—The results of the author's observations on the appearance and periodicity of black rot in 1904 are given. The relation between the appearance of the fungus and the atmospheric conditions are discussed at considerable length.

The treatment of black rot, A. PRUNET (*Rev. Vit., 23 (1905), No. 593, pp. 461–464*).—The author recognizes 2 forms of black rot invasion. The first is caused by the development of the fungus from the spores carried over during the winter, and the second, which appears later, develops from the spores produced during the primary invasion.

For the reduction of the first invasion, all fruits which remain on the vines should be destroyed, as well as the foliage on the ground, and for the later attacks the use of fungicides is recommended. The first application should be made when the plants have attained 2 or 3 small leaves, and this should be followed at intervals of from 8 to 10 days during the season. Fungicides containing 3, 4, and 5 per cent copper sulphate have been tested, and it was found that a 2 per cent solution is to be preferred in combating the black rot.

Combined treatment for the prevention of diseases of the grape, E. ZACHAREWICZ (*Rev. Vit., 23 (1905), No. 593, pp. 476–478*).—For the prevention of downy and powdery mildew and white rot the author recommends an early application of a fungicide composed of copper sulphate 1 kg., powdered soap 1 kg., and water 100 liters.

If the season is exceptionally rainy the addition of ½ kg. each of the copper sulphate and soap is recommended. For the later applications the author recommends powdering the vines with crude plaster 70 kg., powdered soap 5 kg., and sulphosteatite 25 kg. A second treatment with the liquid fungicide just before flowering is recommended, to be followed later by an application of triturated sulphur 80 kg. and sulphosteatite 20 kg.

A new rose disease in Austria, G. KÖCK (*Ztschr. Landw. Versuchsw. Oesterr., 8 (1905), No. 7, pp. 660–666, fig. 1*).—Notes are given on a newly recognized disease of roses. It is said to be caused by *Coniothyrium wernsdorffiæ*, a recently described fungus that attacks the rose canes, causing serious losses. An outline of experiments conducted for its repression is given, in which the canes were treated with a copper lysol mixture, Bordeaux mixture, and a trade solution known as Kerrow. No results are reported.

Sulphur fungicides, J. M. GUILLON (*Rev. Vit., 23 (1905), No. 590, pp. 378–383*).—The author describes the preparation of fungicides composed of Bordeaux mixture and different forms of sulphur.

He says that when freshly mixed these fungicides should have a greenish color, which as the mixture stands, becomes gray and later black. The advantage of the use of such a mixture is that it permits of the simultaneous treatment of grapevines for protection against both powdery and downy mildew. The principal disadvantage is due to the fact that the sulphur does not dissolve but is held in supension in the mixture, and this requires constant stirring.

The settling of the sulphur from the mixture may be retarded somewhat by the formation of a gelatinous oxid or carbonate of copper, but not wholly checked. When the freshly prepared combined Bordeaux mixture and sulphur is properly applied in good season, its action is said to be superior to that of the ordinary Bordeaux, supplemented by the use of dry sulphur.

The adherence of copper fungicides, J. M. GUILLON and G. GUIRAND (*Rev. Vit., 23 (1905), No. 599, pp. 628–631*).—In continuation of the authors' previous experi-

ments (E. S. R., 10, p. 651), the adherence to vegetation of different solutions of copper has been studied. When applied to field conditions, their earlier theoretical conclusions were confirmed to some extent.

The relative adherence of the different solutions when freshly prepared is given in the following order: Those fungicides containing soap, bicarbonate of soda, neutral carbonate of soda, lime, potassium carbonate, eau celeste, and verdigris; fungicides containing gelatin; those to which molasses is added; and finally, neutral verdigris solution. All the solutions were found to be more adherent if applied when very fresh. Bordeaux mixture preserves its adherence for an especially long time if the temperature is high, while the fungicides containing soda compounds, as well as Burgundy mixture, and those containing soap rapidly lose their adhesiveness when the temperature becomes very high.

The fungicides in most common use are grouped in the following order, based upon their adherence: Those containing carbonate of soda and Burgundy mixture, Bordeaux mixture, and neutral verdigris solution.

The adherence of copper fungicides, E. CHUARD and F. PORCHET (*Rev. Vit., 24 (1905), No. 604, pp. 33–37*).—Reviewing the work of Guillon and Gouirand (E. S. R., 10, p. 651) the authors claim that the conclusions given for adherence are based upon theoretical considerations and are not applicable to field practice.

To test the adherence of Bordeaux mixture, soda Bordeaux, and verdigris solutions experiments were carried on in 9 districts, the different solutions being sprayed upon the vines in 2 or 3 per cent solutions for the Bordeaux mixtures and 1 per cent solution for the verdigris, the quantity of liquid used varying from 890 liters per hectare for the first treatment to 1,330 liters for the fourth treatment.

Summarizing the authors' observations the solutions may be ranked in the following order, based upon the average of all their investigations: Neutral verdigris the most adherent, followed by what is called an adherent mixture of verdigris, Bordeaux mixture, and Masson's solution. Under the meteorological conditions in the vineyards of Vaud the neutral verdigris solution was by far the most adherent of any of the fungicides tested.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Winter manual of practice in economic zoology, H. A. GOSSARD (*Ohio Sta. Bul. 164, pp. 36, figs. 11*).—In order to outline correct practice in combating injurious insects during different seasons of the year, the author proposes to issue a manual on this subject for each of the 4 seasons. The present one is the first of the series.

Many of the insects mentioned in this bulletin may be more effectively controlled by insecticide work during other seasons than winter, but good work can be done in winter and the farmer usually has considerable spare time during this season. Attention is called to the importance of clean farming and fall plowing in the control of insect pests. These practices are important in general field work, and even more so in the vegetable garden.

Notes are given on the condition in which various insects hibernate, such as cutworms, grasshoppers, asparagus beetles, squash bug, squash borer, pea weevil, cucumber beetle, Harlequin cabbage bug, bean weevil, etc. The relation of birds to the farmer is also briefly discussed, with an account of the feeding habits of chickadee, white-breasted nuthatch, golden-crowned kinglet, blue birds, woodpeckers, hawks, owls, shrikes, etc.

In a discussion of orchard practice, attention is called to the winter state of certain orchard pests, including various plant lice, scale insects, tent caterpillars, fall webworm, codling moth, bud moth, apple-tree borers, fruit-tree bark-borer, pear psylla, plum curculio, peach-tree borer, and other pests affecting cherry, grape, and small fruits. These pests and others are presented in a table showing the crop affected,

the stage in which the insect passes the winter, the features by which it may be recognized, and the treatment to be applied.

The grouse and wild turkeys of the United States, and their economic value, S. D. JUDD (*U. S. Dept. Agr. Bur. Biol. Survey Bul. 24, pp. 55, pls. 2*).—An account is given of the feeding habits of prairie hen, heath hen, lesser prairie hen, sharp-tailed grouse, sage grouse, ruffed grouse, Franklin grouse, dusky grouse, willow ptarmigan, white-tailed ptarmigan, and wild turkey.

In connection with prairie hen and ruffed grouse an account is also presented of their preservation and propagation. The 12 species of grouse which occur within the limits of the United States including Alaska may be arranged in three groups according as they occupy the open plains, forested regions, or the mountain summits. Attention is called to the diminution in numbers in most of these important game birds, including wild turkey, and to the desirability of having experiments instituted to determine the feasibility of propagating them in a semidomesticated condition.

Detailed notes are given on the feeding habits of all species concerned, as based on the examination of stomach contents.

A new method of destroying field mice, E. SCHRIBAUX (*Jour. Agr. Prat., n. ser., 9 (1905), No. 22, pp. 708–710*).—A comparison was made to determine the effectiveness and relative cost of baryta bread and Loeffler's virus in destroying field mice.

As a result of these experiments it was found that baryta was not only very efficacious in destroying mice but was easy of application and comparatively inexpensive. The treatment of 1 hectare of infested ground with baryta cost about one-half as much as treatment with Loeffler's virus by the ordinary method and about the same as the modified method of applying the virus. The virus, however, in the author's opinion suffers from the disadvantage of being uncertain in its effects.

Injurious insects and other animals observed in Ireland during the year 1904, G. H. CARPENTER (*Econ. Proc. Roy. Dublin Soc., 1 (1905), No. 6, XIV, pp. 281–305, pls. 4*).—*Tipula oleracea* continues to cause damage to cereals by attacking the roots. In some localities whole fields of oats were destroyed by the larvæ of this pest.

In controlling the insect it is desirable that pastures be closely grazed before plowing, and that potatoes or a similar crop be grown on the soil before oats and other cereals. Biological and economic notes are also given on the frit fly, *Chlorops tæniopus* on barley, millipedes, *Tylenchus devastatrix* on oats, cabbage-root maggot, *Pegomyia betæ*, pea weevil, *Lipura ambulans* and *Lohmannia insignis* on kidney beans, *Acidia heraclei* on celery, pear midge, apple-plant louse, black-currant mite, *Rhabdophaga heterobia* on willows, etc.

The study of insects, M. T. COOK (*Estac. Cent. Agron. Cuba Circ. 14, pp. 7, pls. 3*).—A brief account is given of the structure and classification of insects for the use of farmers and fruit growers.

Insect notes (*Agr. News [Barbados], 4 (1905), Nos. 90, p. 298; 91, p. 314; 92, p. 330, figs. 4*).—Citrus plants are said to have been attacked by *Epicærus ravidus*. Brief notes are given on beneficial insects in cotton fields, cane fly in Barbados, hair-follicle mite of pigs, corn earworm, knapsack sprayer, and spraying cattle for ticks.

Entomological notes, J. KOTINSKY (*Hawaii. Forester and Agr., 2 (1905), No. 9, pp. 266–269*).—In this article the author discusses mango weevil, Asiatic ladybird, towoomba ladybird, and San José scale.

The Asiatic ladybird has been introduced into Hawaii, but the importance of this beetle in the destruction of scale insects in the Territory has not been determined. *Rhizobius towoomb* was observed feeding upon various scale insects. The present status of San José scale was also briefly outlined.

Report of the nursery inspector, A. E. STENE (*Ann. Rpt. Bd. Agr. R. I., 20 (1904), pp. 24–43, pls. 2*).—A copy is given of the nursery inspection law of Rhode Island with a commentary on the purpose and operation of the law. Brief notes are

also given on fumigation and inspection under the law and the construction of fumigation houses. Brief abstracts are also given of the inspection laws of other States.

Injurious insects, F. CORBOZ (*Chron. Agr. Vaud, 18 (1905), Nos. 11, pp. 265–269; 12, pp. 290–293*).—An account is presented of the habits, life history and means of combating cabbage maggot, *Ortalis cerasi*, onion maggot, larvæ of crane flies, plant lice on apple, pear, plum, peach, cherry, and gooseberry, *Lecanium persicæ*, and oyster-shell bark-louse.

Field experiments and observations on insects injurious to Indian corn, S. A. FORBES (*Illinois Sta. Bul. 104, pp. 95–152, fig. 1*).—Corn suffers considerable injury from year to year from the attacks of timothy billbugs, of which *Sphenophorus parvulus* was perhaps the most important species observed in the work reported in this bulletin.

In timothy fields near infested corn from 50 to 75 per cent of the timothy bulbs were infested. Adjacent corn fields were injured so that the yield was reduced from 50 to 20 bu. per acre. Careful observations in one field indicated that billbugs had affected about 29 per cent of the hills of corn, diminishing the number of stalks to the extent of 14 per cent and the number of ears 40 per cent. In this field the total loss was estimated at 18 per cent of the crop. A large proportion of this injury may be prevented according to the author's observations by early fall plowing of the timothy sod, and it is recommended that corn should not be planted on timothy sod recently plowed.

The corn-root aphis was carefully studied from the standpoint of its life history and also with regard to successful remedial measures against it. In this study observations were made on the agency of ants (*Lasius alienus*) in carrying the root lice from place to place. In work on insecticide remedies against this pest it was found that by means of disking the ground 3 or more times before the corn was planted the number of hills infested by ants was reduced by 64 per cent and those nfested by the root lice by 82 per cent.

In one instance a single treatment with the disk harrow, as soon as the ground was dry enough to be worked, reduced the number of insects in the field by 90 per cent. This remedy is, therefore, strongly recommended on account of the fact that the extra tillage is not only effective in destroying the corn-root aphis but is of advantage in putting the soil in better condition for the corn crop. Incidentally, it was observed that infested corn land planted once to oats becomes freed of the root aphis.

Elaborate experiments were carried out in determining suitable insecticide methods in controlling chinch bugs. In the use of barriers it was demonstrated that chinch bugs could be effectively kept in check for 4 weeks by means of a strip of coal tar which cost at the rate of $22.40 a mile. In dry years the barrier must be kept intact for 10 days and in wet years perhaps as long as 30 days. It was found necessary to pour fresh tar along the line about 3 times every 2 days. In case the barrier, for any reason, should prove ineffective the chinch bugs may be destroyed by the use of kerosene emulsion. For this purpose a 4 per cent emulsion was found highly effective and not injurious to the corn.

The emulsion was used at the rate of about 2 gal. per acre and was simply flirted upon the corn by the hand. A single treatment was, in some cases, sufficient to reduce the chinch bugs below the danger point. It required a man about 2 hours to treat an acre which would give an average of about 5 acres for a day's work. Whale-oil soap at the rate of ½ lb. to 1 gal. of water is also found to be a safe and successful insecticide for the destruction of chinch bugs, but its cost is about 3 times that of the kerosene emulsion.

The literature relating to the use of the gasoline blast lamp in the destruction of insects is reviewed in considerable detail. The author had already tested this device in the destruction of other insects and experiments are reported in the bulletin of its

effectiveness in the control of chinch bugs. It was found that by giving 2 or 3 treatments at intervals sufficient to allow the chinch bugs which fall off uninjured to crawl upon the corn again, badly infested corn could be almost completely freed from chinch bugs, but corn was almost sure to be somewhat injured unless care was exercised.

Insects and diseases of tobacco, M. T. COOK and W. T. HORNE (*Estac. Cent. Agron. Cuba Bul. 1, pp. 23, pls. 7*).—In this account the author devotes attention chiefly to the tobacco horn worm, cutworms, species of Prodenia, *Epitrix parvula*, cigarette beetle, and other less important tobacco insects.

A test was made of fumigating infested tobacco with bisulphid of carbon and hydrocyanic-acid gas. These materials were used at a greater strength than was required to destroy the cigarette beetles or other insect pests. Apparently the quality of the tobacco was not injured thereby. Notes are also given on other insecticide treatments for tobacco insects together with an account of mosaic disease, tobacco leaf spot, *Orobanche ramosa*, and other parasites.

Insect pests of the carrot, P. LESNE (*Jour. Agr. Prat., n. ser., 10 (1905), No. 27, pp. 16–19, pl. 1*).—The larvæ of the crane fly are reported as causing great damage to carrots. Notes are also given on *Psila rosæ*, *Depressaria nervosa*, etc.

The potato moth, C. FULLER (*Natal Agr. Jour. and Min. Rec., 8 (1905), No. 9, pp. 873–876, pl. 1*).—A serious outbreak of this insect is reported in which about 25 per cent of the potatoes on one estate were destroyed for several years in succession. The habits of this pest are briefly discussed.

In preventing serious injury from the potato moth it is desirable that infested seed should never be planted; the soil should be thoroughly cultivated and care be taken not to leave any tubers exposed since they may become affected in the field. The moths may be captured to some extent by the use of lantern traps. Potatoes should be stored in rooms, barrels, or other receptacles which the moths can not enter. Bags do not protect the tubers from infestation.

Caterpillars which may hatch upon the potatoes between the time of digging and storing may be destroyed by dipping the tubers in a solution of corrosive sublimate.

The social organization and breeding habits of the cotton-protecting kelep of Guatemala, O. F. COOK (*U. S. Dept. Agr., Bur. Ent. Bul. 10, tech. ser., pp. 55*).—The report presents evidence to show that the breeding habits of the Guatemalan kelep and its methods of founding new colonies are essentially different from those of true ants and quite strikingly resemble those of the honey bee.

In the author's opinion this type of organization will facilitate the establishment of the kelep in the cotton fields of the South, provided the insect is able to withstand the climatic conditions of that region. The author discusses in considerable detail the social organization of the kelep with comparative notes on the organization of other social insects, including the ants, termites, bees, bumblebees, etc.

As a result of a continued study of this insect it is believed that it furnishes considerable protection against the boll weevil, does not attack plants, is not a true ant, and may be established in colonies in the Texas cotton fields.

Spraying experiments for San José scale in 1905, T. B. SYMONS and A. B. GAHAN (*Maryland Sta. Bul. 107, pp. 57–62*).—Spraying is now recognized in Maryland as a part of the general routine of orchard work, and satisfactory results obtained from intelligent spraying indicate the profit from this operation.

During the year a number of insecticides were tested. Kerosene limoid in a 20 per cent solution interfered very little with the breeding of San José scale and the trees were nearly as badly infested in the fall as were untreated trees. In 25 per cent solution the insecticide was slightly more satisfactory, but in no case did the results compare with lime, sulphur, and salt.

Lime, sulphur, and caustic soda without cooking gave satisfactory results, but was not as effective as boiled lime and sulphur. Lime and sulphur (20–15) or lime, sulphur, and salt (20–15–12) boiled for 45 minutes gave very good results, and demonstrated anew the effectiveness of this wash. The results obtained from the use of Kill-O-Scale, Con-Sol, scalecide, and horicum were not promising. The author recommends lime and sulphur as the most satisfactory spray for San José scale. Wherever possible it is best to boil the mixture, otherwise a fairly satisfactory solution may be made by the use of caustic soda.

Formulas are given for the preparation of these insecticides. Where only one application is made it is recommended that treatment be postponed as late as possible in the spring.

The San José scale in Mississippi, and the lime-sulphur-salt wash, G. W. Herrick (*Mississippi Sta. Bul. 90, pp. 15, figs. 5*).—San José scale has been known to occur in Mississippi since 1897.

Lime-sulphur-salt wash is believed to be the best remedy for this pest. A formula, 20–15–10–45 is recommended, and the author boiled the mixture for 2¾ hours. When applied in February during a rain storm the results were not wholly satisfactory, but a second treatment in December destroyed about 90 per cent of the insects. The author states that the mixture can be made satisfactorily by boiling 1 hour. Brief directions are given regarding pumps, nozzles, pruning orchards, summer treatment, etc.

In one case an orchardist was able to hold the scale insect in check by severe pruning and painting the branches and trunks with a thick coat of lime-sulphur-salt wash. For summer treatment kerosene emulsion prepared according to the formula 2 lbs. soap, 4 gal. soft water, and 8 gal. kerosene is recommended.

Report on work done in 1901–2 in the control of San José scale and other dangerous insect and fungus pests, J. H. Stewart (*West Virginia Sta., 1903, pp. 64, pls. 5*).—In this report the author presents a financial statement of the disbursements and receipts in the work of exterminating nursery and orchard pests, and also an account of the experiments carried out along this line.

The purpose of the State law under which the work was carried on was to prevent the introduction of insect and fungus diseases or their further distribution after being introduced, the inspection of nursery stock and orchards, and the adoption of measures for eradicating pests. A list is given of the nurseries inspected with notes on the extent of work done. During the years under report 98 orchards, aggregating about 270,000 trees, were inspected. The distribution of San José scale was mapped out.

Experiments were carried out in controlling San José scale by natural enemies, fumigation, and spraying. In orchard work fumigation suffers from several disadvantages, including expensiveness, inefficiency, and danger. Notes are given on the application of crude oils, whale-oil soap, lime-sulphur wash, potash-sulphur spray, and other insecticides. A number of bulletins previously issued by the station and already noted are included in the report.

The San José scale, A. Maclellan (*Ann. Rpt. Bd. Agr. R. I., 20 (1904), pp. 114–116*).—The economic importance of this pest is briefly discussed. As remedies for the San José scale, the author recommends a lime-sulphur-salt mixture containing 40 lbs. lime, 20 lbs. sulphur, and 15 lbs. salt, as well as other similar formulas.

The San José scale and gypsy moth, E. H. Armstrong (*Ann. Rpt. Bd. Agr. R. I., 20 (1904), pp. 102–119, pl. 1*).—Particular attention is given in this article to a discussion of the appearance, life history, habits, and distribution of the gypsy moth with especial reference to suitable means for controlling the pest.

The black-currant gall-mite, P. M. Thomson (*Mem. Roy. Caledonian Hort. Soc., 1 (1905), pt. 1, pp. 63–75, figs. 3*).—This account of the habits, life history, and

means of combating *Eriophyes ribis* is largely quoted from the writings of C. Warburton. It is urged that in order to combat this pest successfully all the fruit growers of a given district must cooperate.

Diaspis pentagona on the mulberry and other insect pests (*Crón. Agr. [Argentina], 1 (1905), No. 7, pp. 91-99*).—*Diaspis pentagona* is said to be one of the most important pests of mulberries, and notes are given on its habits and life history and on artificial methods for controlling it. These methods include the use of mixtures containing heavy oil of tar and carbonate of soda or kerosene fish oil and carbonate of soda.

The mango weevil in Hawaii, D. L. VAN DINE (*Hawaii. Forester and Agr., 2 (1905), No. 8, pp. 231-233*).—*Cryptorhynchus mangiferæ* was found in July, 1905, in the seeds of mangoes.

It appears that this mango pest, while widely distributed throughout the Tropics, has been recently introduced into Hawaii. The life cycle of the insect is passed chiefly within the seed and the pest is therefore a difficult one to combat. In the first lot of mangoes examined about 60 per cent was found to be infested. A strict quarantine is recommended, together with the destruction of all infested fruits which fall to the ground. If the adult beetles feed upon the leaves of the mango they may be poisoned by arsenicals.

Two new shade tree pests, M. V. SLINGERLAND (*New York Cornell Sta. Bul. 233, pp. 47-62, figs. 8*).—The author reports the occurrence of *Kaliosysphinga ulmi* on English and Scotch elms.

This insect probably occurs quite generally in New York State. Sometimes 20 or more larvæ were found mining in a single leaf. The larvæ produce blisters on the elm leaves, which show a dirty white color and shrivel up. On the European alder *K. dohrnii* was observed. This insect also produces brown mines or blisters on the leaves of the European alder. It is believed that it was introduced into America about 20 years ago. The pest has been noted in a number of localities in New York State. The life histories of both species are discussed.

In combating these pests it has been found sufficient to bury the cocoons from 2 to 4 in. under the soil. By removing 1 or 2 inches of the sod or soil from beneath infested trees about May 1 and burying it or otherwise treating it the pest can be controlled.

The fir Pissodes in the Vosges, M. HENRY (*Bul. Soc. Sci. Nancy, 3. ser., 6 (1905), No. 2, pp. 19-26, pl. 1*).—The author describes *Pissodes piceæ*, with notes on its habits, life history, and injurious effects upon the fir trees. In order to combat this pest it is desirable to mark all trees which show signs of infestation during the winter and to cut these trees before the insects emerge in the spring. After such trees are felled the bark should be removed in order to destroy the beetles underneath it.

The buffalo carpet beetle, J. FLETCHER (*Canad. Ent., 37 (1905), No. 9, pp. 333, 334, fig. 1*).—This pest appears to be increasing in importance in Canada. In some localities it has been found in considerable numbers on flowers out of doors.

Notes are given on the habits and life history of the pest. It is suggested that the beetle may be prevented from entering houses by the use of fine mosquito netting put on early in the season. Carpets should be regularly and thoroughly beaten out of doors, and all crevices should be treated with benzine, gasolene, or some similar insecticide.

Modern beekeeping; its helps and hindrances, J. W. BLAKE (*Mem. Roy. Caledonian Hort. Soc., 1 (1905), pt. 1, pp. 42-47*).—A brief discussion is presented of the comparative merits of different breeds of bees, the practical devices necessary for successful beekeeping, foul brood, and other hindrances which may be encountered in the business.

Sericulture in Italy, China, and Japan, H. P. SMITH ET AL. (*Mo. Consular Rpts. [U. S.], 1905, No. 296, pp. 337-388*).—The present reports are in response to a cir-

cular letter addressed to the consular officers in Italy, China, and Japan, requesting an investigation of sericulture as conducted in those countries.

The points covered by the reports include the raising of cocoons, silk reeling, number of workmen, status, training, and compensation of the workmen, mulberry culture, hatching of silkworm eggs, silk manufacture, storage of cocoons, diseases of silkworms, government aid of sericulture, etc.

Report on the condition of the Italian silk trade and on the yield of cocoons in Italy in 1904, P. CHAPMAN (*Diplo. and Cons. Rpts. [London], Misc. Ser., 1905, No. 632, pp. 9*).—The Italian silk market was in an unfavorable condition at the beginning of the breeding season for 1904. The price of raw silk rose considerably, so that certain manufacturers deserted the market, thus causing a fall in the value of raw silk. Notes are given on the results of breeding experiments during 1904. The cross white-yellow breeds are preferred in Italy, especially those of Chinese origin.

FOODS—HUMAN NUTRITION.

A digest of Japanese investigations on the nutrition of man, K. OSHIMA (*U. S. Dept. Agr., Office Expt. Stas. Bul. 159, pp. 224*).—The Japanese have for a number of years been actively engaged in experiments which have to do with the nutritive value of foods, food requirements under different conditions as regards occupation and environment, and similar topics, and have also studied many of the more technical questions connected with the general theories of nutrition.

In this digest the author has summarized dietary studies, digestion experiments, and experiments in which the income and outgo of nitrogen were determined, and has discussed the work at considerable length. Many of the investigations included have been published only in the Japanese language, and hence were not accessible to most investigators outside of Japan.

The digestibility and nutritive value of cottage cheese, rice, peas, and bacon, H. SNYDER (*Minnesota Sta. Bul. 92, pp. 259–275*).—Using healthy men as subjects, the digestibility of cottage cheese, rice, dried peas (soup or purée), and bacon was studied.

These foods were combined with one another and with other articles to constitute simple rations, but in such a way that the nutrients furnished by the foods specially studied constituted a large proportion of the total ration. Thus, in the experiment with cottage cheese 1.1 lbs. was consumed on an average per man per day, this amount supplying over 40 per cent of the total protein and 28 per cent of the total fat of the ration. In addition to the usual experimental data the nitrogen and specific gravity of the urine were recorded. The following table shows the average digestibility of the rations studied:

Coefficients of digestibility of rations containing cottage cheese, rice, peas, and bacon.

Kind of diet.	Protein.	Fat.	Carbohydrates.	Available energy.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*
Cottage cheese ration	95.30	95.44	97.54	90.36
Rice ration	91.46	96.10	97.77	89.81
Dried peas and rice ration	87.14	94.42	97.19	90.01
Bacon and peas ration	83.90	96.17	95.82	87.08
Bacon and cottage cheese ration	94.42	96.78	98.42	89.57

According to the author 95 per cent of the fat and the protein and 97 per cent of the carbohydrates of cottage cheese alone were digested, while 90 per cent of the energy was available to the body. In the case of rice the values are 83 per cent protein, 98 per cent carbohydrates, and 90 per cent available energy. The values calculated for

peas alone were 80.4 per cent digestible protein and 96.20 per cent digestible carbohydrates, and for bacon 92 per cent protein (when combined with cottage cheese and bread) and 96.17 per cent fat. When eaten with peas the author states that the coefficient of digestibility of protein was lower.

The principal conclusions drawn from the experiments were in effect as follows:

Cottage cheese prepared from skim milk and enriched with cream is a cheap, digestible, and nutritious food, and when the materials for its preparation are produced on the farm it is one of the most economical foods that can be used. At 2 cts. per quart for skim milk and 35 cts. per quart for cream cottage cheese compares favorably with meats at 11 cts. per pound. No digestion disorders were experienced by any of the subjects on account of consuming such a large amount of cottage cheese per day. The men were all employed at hard farm labor, and the ration of which cottage cheese formed an essential part gave entire satisfaction.

Rice is easily digested when well cooked, but is no more completely digested than other cereal foods. In these experiments the carbohydrates (starch) of rice were more completely digested than the proteids. The proteids of rice were not as completely digested as the proteids of wheat bread. Rice is a food which supplies a large amount of carbohydrates and can be used to best advantage when combined with such foods as peas, cottage cheese, and meats, which are rich in protein. The rice samples used in these digestion trials were selected types of American grown rice, and the analyses show that they contained a larger amount of nutritive than is present in average imported rice, being equal in food value to flours of low gluten content.

When peas are used in the ration they supply a large amount of protein, although the proteids of peas are not as completely digestible as the proteids of rice and other cereals. Peas supply the body with about the same amount of digestible nutrients as beans. When judiciously combined with other foods peas form one of the cheapest sources of proteids for making well-balanced rations.

Lean bacon in a ration supplies a large amount of digestible nutrients and available energy. Compared with other foods bacon fat has a high coefficient of digestibility. The proteids of bacon were also found to have a high digestion coefficient. Lean bacon contains as much protein and about twice as much digestible fat as other meats, making it at the same and even at a higher price per pound a cheaper food than many other meats.

Bacon fat is easily digested, and when combined with other foods it appears to exert a favorable mechanical action upon digestion.

In a number of the tests milk constituted a part of the diet. The actual digestibility of rations in which milk was used was higher than the calculated digestibility of the individual foods, showing that when combined with other foods milk exerts a favorable influence upon digestibility.

The specific qualities of some digestive ferments, K. KIESEL (*Arch. Physiol. [Pflüger], 108 (1905), No. 6–7, pp. 343–368*).—Experiments with the proteolytic and milk-coagulating ferments of dogs and cattle led to the conclusion that, with the exception of the trypsin and pancreas rennin of the dog, these ferments have a specific action upon the casein of the respective animals.

The importance of specific differences of ferments in infant feeding is spoken of. According to the author the casein of cows' milk and dogs' milk possesses different properties. When the former is heated to a temperature of 90° C. or above it becomes in part insoluble in alkali, which is not the case with dogs' milk casein. On the other hand, when dogs' milk casein is heated to 90° C. or above it unites with more alkali than the unheated casein. In other words, it has become acid by heating.

Chinese bean oil, W. KORONTSCHEWSKY and A. ZIMMERMANN (*Vyestnik Obshch. Hig., Sudeb. i Prakt. Med., 1905, May; abs. in Biochem. Centbl., 4 (1905), No. 8–9, p. 292*).—Tests with soldiers showed that 95 to 100 per cent of bean oil, such as is used

in China as a culinary fat, is digested. When fresh this material is conceded to be a valuable nutrient. The oil (which was presumably made from soy beans) is rich in olein.

The fat-cleaving ferment of the mucous membrane of the stomach, A. FROMME (*Beitr. Chem. Physiol. u. Path.*, *7* (*1905*), *No. 1-3*, *pp. 51-76*).—The experiments reported furnished an additional demonstration of the presence of a fat-cleaving ferment in the mucous membrane of the stomach. One of the questions considered has to do with differences in the fat-cleaving ferment obtained from different animals.

The extent of fat digestion in the stomach, A. ZINSSER (*Beitr. Chem. Physiol. u. Path.*, *7* (*1905*), *No. 1-3*, *pp. 31-50*).—Experiments with normal and diseased subjects are reported. According to the author's results 25 per cent of the fat emulsion taken by the normal subjects had undergone cleavage after an hour's stomach digestion. This value is regarded as very probably an underestimate.

On the influence of copious water drinking, P. B. HAWK (*Reprinted from Univ. Penn. Med. Bul.*, *18* (*1905*), *No. 1*, *pp. 53*).—Three experiments are reported with healthy men in which comparatively large amounts of water (3,100 to 4,500 cc. daily) were added to a uniform basal ration which contained in the fore and after periods 500 cc. of water per day. Some of the principal conclusions which were drawn follow:

"Copious water drinking causes an increased excretion of nitrogen and phosphorus by the urine. The increase in the amount of nitrogen eliminated is due, primarily, to the washing out of the tissues of the urea previously formed, but which has not been removed in the normal processes, and secondarily, to a stimulation of proteid catabolism. The increase in the excretion of phosphorus is due to increased cellular activity, and the accompanying catabolism on nucleins, lecithins, and other phosphorus-containing bodies."

In one instance the increase in the nitrogen excreted in the urine after the ingestion of 9,000 cc. of water in 48 hours was 1.085 gm., or 9.8 per cent above the normal output.

The course of the sulphur excretion, the author states, showed a general tendency to run parallel with that of nitrogen, although it was somewhat irregular.

The influence upon the phosphorus excretion was distinctly different from that of nitrogen or sulphur. "In every instance the excretion of phosphorus was increased above the normal on each day of the water period, the maximum excretion occurring, with absolute regularity, on the second day of the increased water ingestion. There was a constant tendency for the largest percentage of the ingested fluid to be excreted by the urine on the days of copious water drinking. This was indicated by an elimination of 28.5 per cent on an ingestion of 2,300 cc. of fluid, as compared with an elimination of 90.6 per cent on an ingestion of 6,400 cc. of fluid."

Concerning the extractive material of muscular tissue. II, Carnitin, W. GULEWITSCH and R. KRIMBERG (*Ztschr. Physiol. Chem.*, *45* (*1905*), *No. 3-4*, *pp. 326-330*).—From meat extract the authors claim that a new substance was isolated for which the name "carnitin" is proposed. (For earlier work see E. S. R., 12, p. 1076.)

The hydrolysis of proteids. II, Gelatin, Z. H. SKRAUP (*Monatsh. Chem.*, *26* (*1905*), *pp. 243-264; abs. in Biochem. Centbl.*, *4* (*1905*), *No. 5*, *p. 137*).—The cleavage products of gelatin obtained by hydrolysis were studied and compared with bodies obtained in a similar way from casein. A new acid, for which the name "Leimsäure" was proposed, was identified.

The hydrolysis of meat extracts, K. MICKO (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, *10* (*1905*), *No. 7*, *pp. 393-415*).—The hydrolysis of meat extract yielded considerable alanin and in addition glycocol and leucin.

The protective power of asparagin, M. MÜLLER (*Fühling's Landw. Ztg., 54 (1905), No. 13, pp. 437-441*).—Investigations showed that intestinal bacteria used asparagin as a nitrogenous nutrient in preference to proteid bodies which are soluble with difficulty. The nutritive value of the more complex bodies formed from asparagin by the micro-organisms and the bearing of this synthesis upon the nutrition of herbivora are spoken of.

The value of inorganic salts in metabolism, A. HIRSCHLER and P. VON TERRAY (*Ztschr. Klin. Med., 57 (1905), No. 1-2; abs. in Biochem. Centbl., 4 (1905), No. 8-9, p. 258*).—Experiments with young dogs showed that an egg diet with a high content of phosphorus in the form of lecithin was more favorable to gains in nitrogen and body growth than a milk and dried meat diet. Clinical experiments are also reported.

Measuring the body temperature through long periods, E. OERTMANN (*Arch. Physiol. [Pflüger], 108 (1905), No. 6-7, pp. 300-322, figs. 5*).—The author describes several forms of thermometers which he has devised for recording body temperature, and discusses his methods and those of other investigators. (See also E. S. R., 16, p. 999).

Principles of cookery, ANNA BARROWS (*Chicago: American School of Household Economics, 1904, pts. 1, pp. 1-54, figs. 18; 2, pp. 55-97, figs. 18; 3, pp. 99-139, figs. 13*).—In a series of lessons designed for instruction by correspondence different sources of heat, methods of cooking in water with dry heat, canning and preserving foods, principles of cookery, cooking of meats, vegetables, bread, and related questions are taken up.

Notes on food and diet in Cuba, C. F. LANGWORTHY (*Boston Cooking-School Mag., 10 (1905), Nos. 1, pp. 1-8, figs. 10; 2, pp. 77-79*).—A number of Cuban foods are described and food habits and dietetics briefly discussed.

Studies on an ash-free diet, A. E. TAYLOR (*Univ. Cal. Pubs. Path., 1 (1905), No. 7, p. 71; abs. in Biochem. Centbl., 4 (1905), No. 8-9, p. 258*).—The diet selected furnished 70 to 75 gm. protein, 120 gm. fat, 200 gm. sugar, and less than 0.1 gm. mineral salts per day.

After some days loss of appetite, muscular pains, and other unpleasant symptoms were noted. The metabolism of nitrogen and the assimilation of protein, however, were little affected. The conclusion was reached that the disturbances noted were due to the withdrawal of cations. The results are discussed from the standpoint of physical chemistry.

Meals served for twenty cents at dairies, J. TRIBOT (*Rev. Soc. Sci. Hyg. Aliment., 2 (1905), No. 2, pp. 168, 169*).—Data regarding the food value of meals served at Paris dairies are reported with a view to determining the amount of nutrients supplied. This and the 2 following articles are a contribution to the study of French dietaries.

Meals served at restaurants for twenty-three cents and twenty-five cents, J. TRIBOT (*Rev. Soc. Sci. Hyg. Aliment., 2 (1905), No. 2, pp. 169-176*).—On the basis of data gathered in 5 Paris restaurants, the character and nutritive value of meals served for a low price are discussed.

The physiological value of foods served at cheap restaurants in Paris, J. TRIBOT (*Rev. Soc. Sci. Hyg. Aliment., 2 (1905), No. 2, pp. 176, 177*).—On the basis of data collected from cheap restaurants (soup kitchens) in Paris, frequented by workingmen, the character and nutritive value of the meals served are discussed.

Retail prices of food, 1890 to 1904 (*Bur. of Labor [U. S.] Bul. 59, pp. 148-301, dgm. 1*).—Continuing earlier work (E. S. R., 16, p. 688), statistics have been compiled showing the retail prices of food in a large number of American cities and towns.

Means adopted for the preservation of foods, HALPHEN (*Rev. Soc. Sci. Hyg. Aliment., 2 (1905), No. 1, pp. 81-90*).—In a report presented to a committee of

the Society of Hygiene regarding the use of antiseptics, recommendation is made that the use of chemical preservatives be forbidden with the exception of such well-known preservatives as salt, smoke, sugar, spices, etc.

Food inspection, C. D. WOODS (*Maine Sta. Bul. 119, pp. 137–152*).—Data are given regarding the examination under the State pure-food law of a number of samples of baking powders and vinegars.

"While there were low-grade imitation vinegars on the market, no harmful ingredients were found. The fraud in every case was upon the pocketbook rather than upon the health of the consumer. . . . The makers and handlers of vinegar in the State are in apparent sympathy with the purpose of the law and desire to meet its requirements."

Report of food inspection, C. D. HOWARD (*N. H. Sanit. Bul., 2 (1905), No. 9, pp. 133–145*).—Data are given regarding the samples of honey, canned fruit and vegetables, jellies, extracts, etc., analyzed under the State pure-food law.

Report of work in food laboratory, H. E. BARNARD (*N. H. Sanit. Bul., 2 (1905), No. 8, pp. 118–125*).—Of the 426 samples of food products analyzed in 3 months, 55.4 per cent were found to be adulterated or to vary from the legal standard. The remainder were pure or of standard quality.

Data are given regarding the examination of the adulterated or sophisticated goods, which includes principally canned fruits, jellies and jams, honey, extracts, vinegar, molasses, maple sugar and sirup, meat products, and catsups.

The report regarding the law against adulteration, made to the Chamber of Deputies, FAYOLLE (*Rev. Soc. Sci. Hyg. Aliment., 2 (1905), No. 1, pp. 1–80*).—A summary, discussion, and exposition of the French laws regarding fraud and adulteration.

Special report of analyses of condensed milks and infants' and invalids' foods, C. B. COCHRAN (*Penn. Dept. Agr., Mo. Bul. Dairy and Food Div., 3 (1905), No. 5, pp. 20–27*).—Analyses of condensed milks, malted milks, and similar goods are reported. The conclusion is reached that, as a rule, "the condensed milks put upon our markets are made from milk of fairly good quality."

Corn beef containing flour, H. MATTHES (*Ztschr. Untersuch. Nahr. u. Genussmtl., 9 (1905), No. 12, p. 732*).—Flour was identified as an adulterant of canned corn beef.

[Sweet potato flour], T. M. WHELAN (*Natal Agr. Jour. and Min. Rec., 8 (1905), No. 8, pp. 834, 835*).—Experiments with sweet potatoes at the Winkle Spruit Experiment Farm are briefly spoken of, maturity of tubers and other topics are discussed, and an analysis of sweet potato flour reported.

Rotten eggs for food (*N. H. Sanit. Bul., 2 (1905), No. 9, pp. 149, 150*).—According to data summarized stale or rotten eggs when treated with formaldehyde become odorless and are sold to bakers and others for use in the preparation of foods. Prosecutions for the sale of such goods have been made in Massachusetts by the State board of health.

Judging egg noodles and similar goods, H. LÜHRIG (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 3, pp. 153–159*).—The analytical data reported show, in the author's opinion, that egg noodles change somewhat in composition on storing, but that, whatever the age, it is possible, on the basis of analysis, to judge of the amount of eggs used in their manufacture.

The rancidity of fat, J. KLIMONT (*Österr. Chem. Ztg., 8 (1905), No. 11, pp. 249–253*).—A summary and discussion of investigations on the cause of rancidity of fat.

Concerning damaged tea, P. BUTTENBERG (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 1–2, pp. 110–117, fig. 1*).—Different methods of packing tea are discussed, with special reference to the possibilities of contamination with lead used for lining tea chests or other packages.

According to the author, there is little danger except in the case of tea which has become moist in some way. If the tea chests become wet in transport, considerable lead may be present in the tea and should be determined in judging of the possible use of such damaged goods.

Pure food division, H. D. GIBBS (*Health Dept. San Francisco, Bul., 1905, July, pp. 17-22; Aug., pp. 10, 11*).—The data reported cover the results of an examination of 215 samples of dry red California wines collected in the city and county of San Francisco. D. F. Ragan contributes some information regarding the amount of adulterated wine.

Judging the quality of wine vinegar, W. FRESENIUS (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 1-2, pp. 121-129*).—A paper with a discussion presented before the meeting of German Food Chemists in Dresden, 1905. In the author's opinion special attention should be paid to the amount of glycerin present in wine vinegar, as this offers a means of judging of the quality of the product.

ANIMAL PRODUCTION.

Alfalfa for the growing and fattening of animals in the Great Plains region, I. D. GRAHAM (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 242-267, pls. 5*).—In a discussion of alfalfa, a crop which, in the author's opinion, has revolutionized animal husbandry of the Great Plains region, data based largely on the work of the experiment stations and the experience of feeders and breeders are summarized.

Some of the questions considered are the composition and digestibility of alfalfa, the calculated cost of nutrients supplied by alfalfa and other feeding stuffs, the value of alfalfa hay cut at different periods of growth, alfalfa as a pasturage, soiling, and hay crop, alfalfa meal, and the value of alfalfa, fresh and cured, for different kinds of farm animals and for poultry. The importance of this crop as a honey-producing plant is also spoken of.

Finely ground, kiln-dried alfalfa hay is called alfalfa meal, and the author states has given satisfactory results as a feeding stuff. "The commercial article is made from selected alfalfa and mixed with sugar-beet molasses in the proportion of 75 per cent alfalfa and 25 per cent molasses."

The high feeding value of alfalfa for all classes of farm animals is pointed out. Some of the author's deductions follow:

Horses and mules, the author states, "thrive on alfalfa pasture. . . . While . . . alfalfa is too rich a food for mature horses unless used in combination with some other roughness, it is an excellent feed for young horses, as it seems to contain just the elements necessary to develop bone, muscle, and consequent size. Caution should be used, however, in feeding alfalfa to horses, particularly if they have not been accustomed to it. Like other concentrated feeds, it seems to stimulate all the physical processes to such an extent that various disorders of the digestive system may appear. This is particularly noticeable in the urinary and perspiratory glands. . . .

"When alfalfa is fed to horses in considerable quantity the grain ration must be proportionately reduced and an abundance of other roughness furnished. When horses have attained a mature age and it is desirable to change from other hay to alfalfa, this change must be very gradual, and the alfalfa selected for this purpose should be more advanced in growth at the time of cutting than that which is to be fed to cattle or sheep. As a general statement, very ripe alfalfa hay is the best to use for work horses and driving horses, while that prepared in the usual way—that is, cut when the field is about one-tenth in bloom—is better for the colts. In any event, horses that are fed alfalfa hay must be given abundant exercise."

For dairy and beef cattle and for sheep alfalfa has given very good results. As regards the use of alfalfa hay for pigs, the author states that "it is better to cut it

early so that a larger proportion of leaves may be saved and consequently a larger proportion of protein conserved. . . . A late cutting, after the leaves have fallen somewhat and the stem hardened, is better for horses, but for pigs, especially growing pigs, the crop should be so harvested as to save the largest number of leaves. Experience teaches also that the third or fourth crop is better for pigs because it is softer and more palatable. It is always wise to provide some sort of a trough or rack with a floor in it for feeding alfalfa to hogs. . . .

"Alfalfa in its green state, or when used as hay or ensilage, is a first-class poultry food. Poultry will pasture on it during the summer and thrive. . . . It is best for poultry to use the last cutting of alfalfa, as it is softer in texture, has a larger proportion of leaves, less woody matter, and is more succulent than any other cutting. While poultry of all classes will eat alfalfa hay, or at least the leaves from it, and thrive, it is undoubtedly a better practice to chop it or grind it and mix it with a grain ration. A good practice is to steep the alfalfa hay in hot water and let it stand for several hours before feeding."

The report reproduces photographs of a number of high-grade animals fattened or fed on alfalfa.

Cocoanut meal as a food stuff (*Agr. News [Barbados], 4 (1905), No. 87, p. 254*).—An analysis, by J. P. d'Albuquerque, of Trinidad cocoanut meal is reported, and the feeding value of this meal briefly spoken of.

Molasses as a food for work animals, W. H. DALRYMPLE (*Breeder's Gaz., 48 (1905), Nos. 6, p. 231; 7, pp. 276, 277; 8, pp. 325, 326; 15, p. 697*).—The importance of molasses as a feeding stuff for horses and mules is discussed, and data collected from 42 Louisiana plantations are summarized.

It is stated that the average amount fed to large mules is 8 to 12 lbs. per head per day, a gallon of blackstrap cane molasses weighing on an average 12 lbs. Chopped hay, peavine, or alfalfa, and some concentrated feed are commonly mixed with this amount of molasses and the whole fed in 3 portions. It is desirable to begin with smaller amounts of molasses when this material is first introduced into the ration.

The utilization of brewers' yeast (*Pure Products, 1 (1905), No. 5, pp. 268, 269*).—Data are summarized regarding the manufacture of feeding stuffs and other products from refuse brewers' yeast.

The destruction of foods and feeding stuffs by micro-organisms. V, The composition of slime due to bacteria, J. KÖNIG, A. SPIECKERMANN, and F. SEILER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 9 (1905), No. 9, pp. 513–528*).—The principal conclusions drawn from the investigations reported follow: Slimes are formed by many bacteria growing not alone on sugar but also on some nitrogenous materials, such as peptone, asparagin, and glycocol. The slime obtained from liquid and solid nutrient media consists largely or entirely of dehydrated carbohydrates, in part fructose and glucose groups and in part galactose groups. Dextrin was not identified. A list is given of the slime-producing bacteria.

Cattle, sheep, and hog feeding in Europe, W. J. KENNEDY (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 77, pp. 98*).—On the basis of personal experience the author summarizes data regarding the cattle, sheep, and hog industry in Great Britain and on the continent of Europe.

"A very wide range of feeding stuffs is used, and diversity of methods prevails both as regards the compounding of rations and the preparation of feed. However, satisfactory results are usually obtained, and the methods employed exemplify in no unmistakable manner that no one combination of feeding stuffs is superior to all others to produce work, meat, milk, or uniform growth and development. For reasons of economy the feeders of each country must use, as far as possible, the feeds whose production is best adapted to the soil and climatic conditions of that country, and which can be grown at home.

"To an American the striking features of European methods are the large use made of roots, linseed and cotton cake, the large proportion of roughage to concentrates fed, the dependence placed on pasture and other green feed, the attention paid to the preparation of the feed, and the effort to use everything grown on the farm. Furthermore, although the most intensive methods are used to fatten cattle for market, the general tendency among breeders is to maintain breeding stock in good condition, but to avoid the extremely fleshy condition which often leads to barrenness and impotency.

"Roots are most extensively used in cattle production in England and Scotland, and these crops are very highly valued. They are fed to dairy cattle as well as to beef animals, but when feeding them to milch cows the best dairymen take pains to avoid tainting the milk by their use. Mangel-wurzels (commonly called mangels or mangolds), turnips, and ruta-bagas (commonly called swedes) are usually grown in Great Britain. In the continental countries, especially in France and Germany, the sugar beet and sugar-beet pulp are used. In some cases carrots are fed, especially to calves, and in the island of Guernsey parsnips are used."

As was the case with cattle, considerable diversity was noted in the methods of feeding sheep and pigs. The rations fed to these animals and to cattle are in many cases described in detail, the amounts of the different feeding stuffs used being recorded. It is the author's belief that European methods can not be adopted by American farmers without change, but that probably many features may be applicable to our conditions.

Special interest attaches to the section devoted to bacon production on account of the acknowledged excellence of the English, Irish, and Danish bacon.

The sheep industry of England, Scotland, Ireland, and France, W. J. Kennedy (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 81, pt. 2, pp. 71-87*).—A reprint from the publication noted above.

The score card in stock breeding, G. M. Rommel (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 76, pp. 54, figs. 7*).—This bulletin is made up of a compilation of the score cards used by breeders' associations in the United States certified by the Secretary of Agriculture and is intended as a supplement to Bulletin 61 of the Bureau (E. S. R., 16, p. 587). The material comprises standards for horses, beef cattle, hogs, and sheep, but does not include those for dairy cattle.

Cattle feeding experiment, H. R. Smith (*Nebraska Sta. Bul. 90, pp. 24, figs. 7*).—Using 5 lots of 10 2-year-old steers, the relative merits of different sorts of coarse fodder as a supplement to corn were studied.

The experimental rations were made up of shelled corn with prairie grass hay, alfalfa hay, and alfalfa hay and corn stover; and of corn and oil meal 9:1 with prairie grass hay and with sorghum hay. In the 24 weeks covered by the test the average daily gain per head ranged from 1.9 lbs. on corn and prairie hay to 2.4 lbs. on corn, alfalfa hay, and corn stover. The greatest range in cost of feed per pound of gain was from 6.49 cts. on the last mentioned ration to 8.27 cts. on the ration consisting of corn, oil meal, and prairie hay.

The coarse fodder required per pound of gain ranged from 3.82 lbs. with the lot fed sorghum hay to 5.19 lbs. with the lot fed corn and prairie hay, and the grain eaten per pound of gain from 7.89 lbs. on the ration containing corn stover to 9.52 lbs. on the corn and prairie hay ration. The greatest profit, $3.32 per steer, was obtained with the alfalfa and corn stover ration, and the smallest, $1.09 per steer, with the corn, oil meal, and prairie hay ration. Some of the author's conclusions follow:

"When the ration consisted of corn and prairie hay, the amount of grain required for each pound of gain was lessened 5 per cent by adding oil meal to the grain ration.

"The cost of producing a pound of gain was not lessened by the addition of oil

meal, but a better finish was secured, which caused the cattle to sell for 15 cents more per hundred. . . .

"Alfalfa is much superior to prairie hay when the grain consists of corn alone. It also proved to be a cheaper source of protein than oil meal. . . .

"Bright, well-cured corn stover fed with an equal weight of alfalfa, the grain consisting of corn alone, gave slightly larger gains than corn and alfalfa, and proved the most economical ration in the experiment. The addition of corn stover may have improved to some extent the corn and alfalfa ration by furnishing greater variety and by its tendency to check scours sometimes caused by alfalfa.

"Sorghum hay returned a value of $4.63 per ton in comparison with prairie hay at $6, each being fed with corn 90 per cent and oil meal 10 per cent. . . .

"While the profit was small, the steers returned a good price for the rough feeds at the market values quoted—high enough to make them profitable crops to grow on the farm. Had the feeds been sold, these values for roughage would not have been secured on the average Nebraska farm, nor would the manure have been left to make the next crop larger."

From this and similar work with yearling steers previously reported (E. S. R., 16 p. 586) the following general deductions are drawn:

"Alfalfa hay is pronouncedly superior to prairie hay for beef production, and the more rapid the extension of the area of land devoted to the production of alfalfa, supplanting the less valuable and lower yielding native hay, the more rapid will be the production of wealth from our soil.

"Native prairie hay, if for any reason it is most available for feeding purposes, should not be fed with corn alone, but rather with corn supplemented with a small quantity of some protein food, such as oil meal, to give more nearly a balance of nutrients in keeping with animal requirements.

"Cornstalks cut and put in the shock immediately after the ears ripen possess a food value which can not consistently be ignored by the farmer, and existing land values warrant the larger utilization of this roughness by the adoption of methods of harvesting that will make such material more valuable for feeding purposes."

Cattle and cattle raising in Brazil, H. von Ihering (*Separate from Jahrb. Deutschsprech. Kolon. São Paulo, 1 (1904), pp. 97–113, figs. 6, map 1*).—In a discussion of the problems of cattle raising in Brazil, Cuyabana, Caracú, Franqueiro, Torino, Zebú, and China cattle are described, as the author considers these breeds of especial importance for the local cattle industry.

Highland cattle, J. Roberts (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 227–241, pls. 4*).—The origin and history of highland cattle, characteristics and various points of the breed, feeding and management, and related questions are discussed. The author calls attention to the fact that there are not many representatives of this breed in the United States and gives some information regarding the whereabouts of the few American herds.

Ration experiments with lambs, 1904–5, G. E. Morton (*Wyoming Sta. Bul. 68, pp. 23, pls. 8*).—The comparative value of alfalfa and native hay, of barley and corn, and of flaxseed (ground without expressing the oil) was studied with 3 lots of 20 lambs and 2 lots of 3 lambs each. In addition to grain and hay all the lots were fed turnips.

At first the flaxseed used was mixed with the turnips, as otherwise the lambs would not eat it owing to its strong taste. After a time, however, it was eaten more readily. With all the rations containing alfalfa hay the nutritive ratio was about 1:5; with the native hay ration it was 1:10.5.

In the 16 weeks of the test the gains made on corn and alfalfa hay and barley and alfalfa hay were 31.2 and 33.1 lbs. per head; on corn and native hay, 20.7 lbs.; on flaxseed, corn, and alfalfa hay, 31.8 lbs.; and on flaxseed and alfalfa hay, 25.7 lbs. Rating turnips at $2 per ton the cost of a pound of gain ranged from 4.68 cts. on corn and alfalfa hay to 6.08 cts. on corn and native hay.

At the close of the feeding test a lamb from each of the lots, except that fed corn and flaxseed was slaughtered. The lamb fed barley gave the largest percentage of dressed weight (68 lbs.) and meat of the best quality. The lamb fed flaxseed and alfalfa hay was rated next as regards weight of dressed carcass, "but the meat was very dark colored and on that account not satisfactory, although it had a very fine flavor." The weight of the caul fat of this lamb was very high owing to the heavy flaxseed feeding. No urinary troubles were noted as a result of feeding flaxseed from which the oil had not been expressed.

According to the author, the investigation shows that "alfalfa and corn and alfalfa and barley are very nearly equal in feeding value, if they can be obtained at the same price. In fact, judging from the general condition of the lambs during the experiment, as well as from the gains made, barley is preferable to corn for feeding in conjunction with alfalfa.

"The ration composed of alfalfa, corn, turnips, and flaxseed evidently closely approaches in value the two just named. The alfalfa and flaxseed ration . . . is of doubtful value where corn or barley can be obtained cheaply and without long hauls. But feeders at points over 10 miles from a railroad who can combine farming with feeding might find it profitable to use flaxseed instead of grain. Flax is a native of the State, growing wild in places, and cultivated varieties yield well.

"Alfalfa, flaxseed, and turnips would make a good ration for a farmer feeder who could not obtain corn or barley cheaply."

The tests with flaxseed and barley have been noted from another publication (E. S. R., 17, p. 585).

Lamb feeding in the San Luis Valley (*Breeder's Gaz., 48 (1905), No. 8, pp. 310, 311, fig. 1*).—The successful use of pea-vine hay for fattening lambs is spoken of.

Notes on the Angora goat industry, G. F. THOMPSON (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 394–399, pl. 1*).—The author's official report as juror for Angora goats for the Louisiana Purchase Exposition is given, as well as information regarding the importation of mohair and Angora goat skins, Angora goats in Porto Rico and Cuba, and other current topics relating to the Angora goat industry. The export duty of £100, which is levied on Angora goats in South Africa, the author notes, practically prohibits their exportation from that country.

A consideration of mohair and mohair growing, with notes on observations in South Africa, G. A. HOERLE (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 400–405, pls. 2*).—Factors which constitute quality in South African mohair, the characteristics of the fleece of South African Angora goats, and other related topics are discussed on the basis of personal experience and observation.

Practical Angora goat raising, C. P. BAILEY (*San José, Cal.: C. P. Bailey & Sons Co., 1905, pp. 97, pl. 1, figs. 21*).—The feeding, breeding, care, and management of Angora goats, the quality of goat mutton, and related topics are taken up.

Proceedings of the horse industry congress, J. M. DE LAGORSSE (*Compt. Rend. Cong. Hippique, 1905, pp. 163*).—This volume contains a report of the proceedings of the congress held in Paris, June 23 and 24, 1905, for the purpose of considering horses and the horse industry, the papers presented at the meetings, with discussions, and related matters.

Fattening draft horses, J. W. COVERDALE (*Breeders' Gaz., 48 (1905), No. 25, pp. 1310, 1311*).—The essential points to be considered in feeding draft horses for the market, according to the author, are the selection of animals of good type and constitutional vigor, starting the grain ration carefully, the selection of a suitable ration when on full feed, toning up the system by giving a little saltpeter and glauber salts, abundance of clean bedding and quarters, and careful grooming and sufficient exercise before selling.

"The amount of each feed should be according to the appetite of the horse. . . . A heavy horse on full feed will eat about 18 ears of corn twice a day, 15 qts. of oats and bran mixed, and about 10 lbs. of hay."

Hunter-horse production in Ireland, W. J. KENNEDY (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 187-226, pls. 8*).—The breeding, feeding, care, and management of Irish hunter horses is discussed on the basis of information gathered by the author on a trip undertaken to study this industry.

It is pointed out that there is much lack of uniformity in Irish hunters, but that nevertheless there has been a ready market for Irish horses of all sorts, those of the highest type being purchased for hunting, while those bred along the same line but deficient in size and quality are sold for other uses and for smaller prices. The various classes for which there is a foreign demand at very good prices are weight-carrying hunters (heavy, medium, and light), mares and fillies for breeding purposes, saddle horses, officers' remounts, troopers' remounts, harness horses, and hack or cab horses.

The points to be observed in judging first-class heavy-weight hunters are given in detail, and the different crosses with hunters which are commonly met with are described. The influence of district and county shows, the work of the department of agriculture of Ireland, and other factors which aid in the development and improvement of the Irish hunter industry are spoken of.

Mount Serle government camel depot, J. DESMOND (*Jour. Dept. Agr. So. Aust., 9 (1905), No. 1, pp. 7-12, figs. 4*).—Information is given regarding the care and management of the government camel herd of 30 males, 45 females, and a number of calves, and also regarding the successful castration of a number of males, an operation commonly supposed to be followed by a high death rate.

The causes of daily variation in body weight, J. LATSCHENBERGER and S. POLANSKY (*Arch. Physiol. [Pflüger], 108 (1905), No. 8-9, pp. 457-472, pls. 2*).—From experiments with 2 horses extending over 186 days the conclusion was reached that the gaseous excretory products are the chief factors which influence daily changes in body weight. Periodicity in the variations was noted.

An investigation into the diurnal variation of the body temperature of nocturnal and other birds, and a few mammals, S. SIMPSON and J. J. GALBRAITH (*Jour. Physiol., 33 (1905), No. 3, pp. 225-238, figs. 13*).—In birds of diurnal habit which were examined (chickens, ducks, pigeons, sea gulls, thrush, etc.), the mean body temperature for 24 hours, as shown by measurements made with a rectal thermometer, was practically the same for all species, namely, 41 to 42° C.

The range of temperature with different species was found to vary greatly, being least in the largest and greatest in the smallest birds. For example, in the domestic duck it was 0.92° and in the thrush 4.27°, while in the birds of intermediate size the range was also intermediate. When sex was considered, the mean temperature of females was found to be higher than that of males.

"The temperature curve of diurnal birds is essentially similar to that of man and other homœothermal mammals, except that the maxima occur earlier in the afternoon and the minima earlier in the morning.

"In nocturnal birds (owls), on the other hand, the curve is inverted, the maximum occurring about midnight or in the early morning and the minimum about noon or shortly after. As in diurnal birds, the temperature is highest during the natural period of activity (night) and lowest during the period of rest (day). The mean temperature is lower and the range less than in diurnal birds of the same size.

"The curves obtained from the rabbit, guinea pig, and dog show the same features as in man, with a few minor differences. Both the mean temperature and the range is less than in birds."

Incubation and incubators, R. H. WOOD (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 286-315, figs. 11*).—A summary of data regarding incubators in which different types of incubators are discussed, the defects of incubators pointed out, and methods of operating incubators and other related topics spoken of.

Incubation and incubators, R. H. WOOD (*U. S. Dept. Agr., Farmers' Bul. 236, pp. 31, figs. 11*).—A reprint of the article noted above.

The poultry industry of Petaluma, California, P. H. LAWLER (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 316–322, pls. 3*).—The author points out that the raising of chickens is not generally a paying business in California, except upon a strip 40 miles wide along the Pacific, though turkeys thrive in all parts of the State. Where practiced, however, the chicken industry is very important, and Petaluma may be fairly regarded as a center of the poultry industry.

Statistics regarding the poultry and eggs produced and shipped, the feeding and care of the poultry, and other similar data are summarized. The breeds of chickens which are more commonly raised in the vicinity of Petaluma are Barred Plymouth Rocks, Brown Leghorns, and White Leghorns, the last-mentioned breed far outnumbering all the others.

The growth of chickens, M. STEFANOWSKA (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 4, pp. 269–271; abs. in Zentbl. Physiol., 19 (1905), No. 16, pp. 581, 582*).—The rate of increase in weight of chickens on a uniform diet was found to progress rapidly until it reached a maximum, and then to take place less quickly. Some differences were noted with males and females, but in general the maximum rate of increase was about the middle of the growing period.

The Buff Orpington duck, D. F. LAURIE (*Jour. Dept. Agr. So. Aust., 9 (1905), No. 2, pp. 85–90, fig. 1*).—The author considers Buff Orpington ducks very satisfactory for duck raising under local conditions, and records some data regarding egg yield. A bird under observation laid 79 eggs in 80 days; a second, 54 eggs in 54 days; a third, 92 eggs in 96 days; and a fourth, 70 eggs in 74 days.

The guinea fowl and its use as food, C. F. LANGWORTHY (*U. S. Dept. Agr., Farmers' Bul. 234, pp. 24, figs. 3*).—Data regarding varieties, habits and care, marketing guinea fowl, the value of their flesh and eggs as food, and similar topics are discussed. As pointed out, these birds are fairly hardy and will gather a considerable part of their food. The flesh is considered excellent, and there is a growing demand for guinea fowl at fair prices, particularly in city markets.

The oyster. A popular summary of a scientific study, W. K. BROOKS (*Baltimore: Johns Hopkins Press, 1905, 2. ed., pp. XVI+225, illus.*).—The principal object of this popular summary of data regarding the oyster and oyster problems, which is based largely on personal experience and observation, is to suggest means of conducting an oyster industry on a rational and economical basis.

The principal addition, in the second edition, the author states, is the section on the transmission of typhoid fever and cholera by oysters. If the micro-organisms causing these diseases and other similar minute forms of life pass into the oyster's stomach they are digested and rendered harmless, but as long as they remain in the gills they may be a possible source of infection if the oyster is eaten raw. The author believes that oysters should not be fattened or floated, but should be marketed directly from salt water.

"In my opinion, no one need fear to eat true salt-water oysters raw, but every fresh-water oyster and every 'fattened oyster' is too dangerous to be eaten raw. . . . [Fattened oysters are simply full of fresh water.] All the fresh water that a 'fattened' oyster has absorbed is at once extracted by cooking, so the 'fattening' of oysters that are to be cooked is not only an unnecessary expense, but a fraud on the consumer, who is sold filthy water from the harbors of cities at the price of oysters."

Imports and exports of animals and animal products, J. ROBERTS (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 469–505*).—A summary of statistical data.

The total value of animals and animal products imported into the United States in 1904 was $112,000,000 in round numbers. The total value of the exports was $249,300,000. The most prominent feature of our international trade in animals and animal products during the calendar year 1904 was a decided increase in imports.

Farm animals in 1904 (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 506–512*).—Statistics are given regarding the number and value of farm animals in the United States, the losses of farm animals during the year, and regarding the amount

and value of the wool products of 1903 and 1904. The total wool product for 1904 was estimated to be 291,783,032 lbs., and its value $64,940,959.

Live stock associations and the markets (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 513–558*).—Addresses and other data regarding live stock, registered stock, pedigree, and breeders' associations are summarized, and statistics given regarding the shipments of live stock and range of prices during the calendar year 1904.

DAIRY FARMING—DAIRYING.

Records of dairy cows in the United States, C. B. LANE (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 75, pp. 184, pls. 17, figs. 6*).—This is a compilation of authentic milk and butter records of pure-bred, grade, and native cows in this country to which numerous private records, having no official endorsement but believed to be reasonably accurate, are added.

In the introduction to the bulletin the author discusses the value of dairy records, methods of keeping records, and raising the standard of production, and in his summary draws conclusions along these lines from the data presented.

Circulars were sent to 600 dairymen making inquiries as to the management and production of their herds. Replies were received from over 200, and of this number 25 per cent stated that they did not keep records, while a still smaller proportion was able to give the cost of keeping their cows. Where a special breed was kept the reports indicated that the owners were more careful in the breeding and management of their cows and secured larger yields and greater profits. An abundance of nutrients returned the greatest profit over cost of food. The proportion of carbohydrates was often excessive. The silo assisted materially in reducing the cost of feed. The construction of stables was often faulty.

The author considers that the average production of dairy cows in this country is hardly up to the profit line and states the fundamental steps to be taken in improving dairy herds as follows:

"Take advantage of variation. While the tendency of nearly all cows raised is to become average cows, a number fall below and a few reach a yield of 500, 600, or even 700 pounds of butter.

"Those above the average should be carefully selected and bred with care and judgment.

"While the test must be used to detect variation and make selections, it is needed particularly to test the progeny, to determine whether the good qualities of the parent have been perpetuated, and to see if any improvement in the offspring has been made.

"Food, care, and management are of the highest importance. Having been carefully selected and having stood the test, the cows must be well fed and cared for if their good qualities are to be retained and improved."

The dairy industry in New Hampshire, I. C. WELD (*New Hampshire Sta. Bul. 120, pp. 69–80, figs. 4*).—This is a brief historical and statistical account of the dairy industry in the State.

The number of milch cows is placed at 129,900, and their average value per head at $32.34. It is estimated that the average cow produces annually 4,223 lbs. of milk. There are, in the State, 1 condensed milk factory, 7 cheese factories, 52 creameries, and 146 stations from which milk is shipped to Boston.

Demonstration experiments on the feeding of dairy cows, conducted at the expense and under the supervision of the government during the winter of 1904-5 (*Bul. Agr. [Brussels], 21 (1905), No. 5, pp. 691–872*).—This is a detailed report of experiments carried out in the different provinces of Belgium in the same manner as in previous years (E. S. R., 16, p. 1010). Conclusions are drawn

from the results of individual experiments, which are very numerous, but not from the work as a whole.

Report of the Brown Swiss Cattle Breeders' Association, 1904 (*Landw. Jahrb. Schweiz, 19 (1905), No. 7, pp. 447-476*).—In this report are included the records of a number of cows of the Brown Swiss breed. The average annual yield of milk of 28 cows was 4,001.4 kg., the average percentage of total solids was 12.94, and of fat 3.81. Similar data for the previous year were noted in E. S. R., 16, p. 698.

Report of the Spotted Swiss Cattle Breeders' Association, 1904, (*Landw. Jahrb. Schweiz, 19 (1905), No. 6, pp. 301-337*).—The average annual yield of 61 cows of this breed was 3,798 kg. of milk, showing an average fat content of 3.85 per cent and 12.97 per cent total solids.

On the importance of a careful system of milking, H. P. LARSEN (*Ugeskr. Landm., 51 (1905), No. 50, pp. 555, 556*).—The results of the introduction of contract milking at a Danish estate are given. The average production of 43 cows the first year, when payment for the milking was based on the amount of butter fat obtained in the milk, was 6,925 Danish pounds milk and 267 lbs. fat (average per cent fat, 3.47), against 5,689 lbs. milk and 222 lbs. fat (average per cent fat, 3.48), during the preceding year. The system of feeding, care, and management of all the cows included in this summary, aside from the method of paying for the work of milking, was the same both years.—F. W. WOLL.

The consumption of milk in the city of Antwerp and its suburbs, F. SMEYERS and E. WEYNANTS (*Rev. Gén. Agron., 14 (1905), No. 10-11, pp. 417-428*).—The total milk consumption of the 371,000 inhabitants was 82,830 liters per day, of which 68,000 liters was fresh whole milk, 1,800 liters whole pasteurized milk, 3,725 liters milk partially skimmed, 7,070 liters skim milk, and 2,235 liters whipped milk.

Is the composition of milk influenced by the food? O. JENSEN (*Landw. Jahrb. Schweiz, 19 (1905), No. 8, pp. 534-559; Rev. Gén. Lait, 5 (1905), Nos. 5, pp. 103-110; 6, pp. 121-128; 5 (1906), Nos. 7, pp. 152-161; 8, pp. 178-185; 9, pp. 198-205*).—This is a continuation of similar investigations previously noted (E. S. R., 16, p. 1009).

The following methods of feeding were studied as regards their influence upon the composition of milk: (1) The addition of different mineral salts to forage composed of hay and aftermath or of grass, (2) feeding decreasing quantities of hay in connection with increasing quantities of peas, by which method the chlorin and alkalies were increased and the phosphoric acid and alkaline earths decreased, (3) feeding increasing quantities of sesame cake and wheat bran with a basal ration consisting of hay, by which method the reverse of the above was secured, and (4) feeding grass from unfertilized meadows and from meadows fertilized in different ways. The detailed report of the investigations contains a description of the methods of analysis employed, a discussion of the influence of lactation on the milk, and the results of the methods of feeding mentioned.

When large quantities of saltpeter were fed the milk showed a trace of nitrate. Large quantities of roots increased the volatile fatty acids. Feeding sesame cake in connection with wheat bran increased the oleic acid content of the milk fat. Feeding stuffs rich in organic phosphorus compounds increased the acidity and the phosphorus content of the milk to a slight extent. Grass very poor in alkalies and phosphoric acid decreased slightly the potassium in the milk and to a more marked extent the acidity of the milk and also decreased the curdling power of the milk with rennet. By changing to green food and also in some cases on pasture the acidity of the milk was increased.

From these results it is concluded that the composition of the milk fat and the natural acidity of the milk may be influenced by means of food and other conditions and that the quantity of certain inorganic milk constituents can be increased or decreased in very extreme cases by feeding, but only within very narrow limits. On the whole the results showed that the composition of milk is not readily influ-

enced by feeding and that it is, therefore, no difficult matter to so use artificial fertilizers and concentrated feeds that no injurious effects upon milk and cheese may result.

Lactic acid in cows' milk, O. H. Nowak (*Amer. Food Jour., 1 (1906), No. 1, pp. 21, 22*).—The author calculates that there is present in milk serum a quantity of organic acid equivalent to 2.5 gm. of citric acid per liter.

The content of preformed sulphuric acid in cows' milk, R. Steinegger and O. Allemann (*Landw. Jahrb. Schweiz, 19 (1905), No. 8, p. 530*).—The analyses made by the authors showed the presence in solution of 0.0823 to 0.1311 gm. of SO_3 per liter. The authors conclude, therefore, that there can no longer be any doubt as to the presence of preformed sulphuric acid in cows' milk.

Contribution to the knowledge of the properties of salty, bitter milk, R. Steinegger and O. Allemann (*Landw. Jahrb. Schweiz, 19 (1905), No. 8, pp. 531–533*).—Milk having a salty, bitter taste is often obtained from cows having a disease of the udder. The authors analyzed a number of such samples and found that the percentages of fat and sugar were greatly reduced. The percentages of ash also showed considerable variations from normal. In general, there was a decrease in P_2O_5, CaO, K_2O, and MgO and an increase in Cl, Na_2O and SO_3.

The viscous fermentation of milk and beer, F. C. Harrison (*Rev. Gén. Lait, 5 (1905), Nos. 4, pp. 73–80; 5, pp. 97–103; 6, pp. 129–136; 5 (1906), No. 7, pp. 145–152*).—The literature of slimy fermentations in milk is reviewed and a bibliography of this subject is given. In addition the author reports in detail studies of 12 species of slime-producing organisms, some of which were isolated by himself.

While the investigations are not as yet complete the author feels justified in concluding that the bacillus isolated from slimy milk by Marshall and the bacillus isolated by Ward are identical with the *Bacillus lactis viscosus* of Adametz. The 12 species were divided into four groups, of which the different members were considered as identical. This division was based upon the morphological and cultural characteristics. The author also studied the nature of the viscous substance formed in such fermentations, and concluded that the viscosity is not produced by a diffusible enzym produced by the micro-organisms, but that the viscous substance is intimately associated with the substance of the micro-organisms.

An experimental investigation of the Budde process for the preservation of milk, R. T. Hewlett (*Lancet [London], 1906, I, No. 4, pp. 209–211*).—The author believes that in hot weather much of the milk delivered in London would be unusable except for the addition of preservatives. While he does not advise their addition he considers that under present conditions the moderate addition of preservatives is less dangerous than a semiputrid milk. The Budde process of treating milk is described and some investigations are reported.

In testing the efficiency of the Budde method, milk was cooled at the dairy immediately after milking and shipped to the laboratory, where it arrived after 4 or 5 hours. Emulsions of cultures of various micro-organisms were added to samples of the milk and treated by the Budde method. Samples were also subjected to the same amount of heat without the addition of hydrogen peroxid, and noninoculated samples were also used as controls.

The organisms tested were *Bacillus diphtheriæ*, *B. acidi lactici*, *B. coli*, *B. typhosus*, paratyphoid bacillus, *B. dysenteriæ*, cholera vibrio, *Micrococcus pyogenes aureus*, *B. tuberculosis*, *B. anthracis* with spores, *B. subtilis*, *B. mycoides*, and *Penicillium glaucum.*

From one to three experiments were made with each organism. The results showed that all the nonsporogenous organisms, both pathogenic and nonpathogenic, were destroyed by the Budde process. The spore-bearing organisms, while not destroyed, were greatly reduced in numbers. The reduction in numbers of organisms by heating alone was not so great as that by the Budde method. In milk

obtained in the ordinary way the number of micro-organisms were reduced by the Budde method over 99.9 per cent.

The author states that milk treated by the Budde method is practically undistinguishable from untreated milk in taste, odor, and appearance and in the rising of the cream, and that such milk will keep perfectly sweet and apparently unaltered for at least 8 to 10 days in hot weather and for a still longer period in cold weather. No increase in acidity is caused by the treatment, and when properly carried out the whole of the hydrogen peroxid is decomposed, and hence at the end of the process no trace of it can be detected in the milk.

The detection, determination, and rate of disappearance of formaldehyde in milk, R. H. WILLIAMS and H. C. SHERMAN (*Jour. Amer. Chem. Soc., 27 (1905), No. 12, pp. 1497–1503*).—The hydrochloric-acid and ferric-chlorid test for formaldehyde in milk was found very satisfactory. Souring of the milk did not in itself affect the delicacy of the test. The gallic-acid test has been found considerably more delicate, but less convenient. The potassium-cyanid method was found satisfactory for quantitative determinations at any concentration greater than 1 to 160,000.

Aqueous solutions of formaldehyde containing 1:5,000 to 1:40,000 of formaldehyde lost strength steadily on standing at room temperature, the loss increasing with the dilution, and due to an actual destruction of the formaldehyde. When added to milk in the proportions of 1:10,000 to 1:40,000 formaldehyde disappeared from 10 to 20 times as rapidly as from aqueous solutions of this same concentration. In aqueous solution formaldehyde decreased in amount from 1:40,000 to 1:160,000 in 28 days, while in milk the same diminution occurred in 2 days. Aqueous solutions of 1:1,000 showed no appreciable loss in 5 months. The rate of disappearance from milk was practically the same, whether formaldehyde was added before or after souring.

Contribution to the knowledge of the influence of formaldehyde upon milk, R. STEINEGGER (*Landw. Jahrb. Schweiz, 19 (1905), No. 8, pp. 512–527, fig. 1*).—The author studied the influence of formaldehyde on the milk fat, milk sugar, action of rennet, and the acidity of milk. Some of the conclusions reached follow:

Formaldehyde when added to milk exerts an influence upon the proteids which is not dependent upon the presence of any organic ferment. Formaldehyde increases the acidity of the milk. Each milk is capable of combining with only a definite quantity of aldehyde which so-called aldehyde number stands in direct relation to the nitrogen, the greater the amount of nitrogen the higher the aldehyde number. This reaction is not influenced by the action of rennet or the decomposition of milk due to long keeping. Formaldehyde increases also the acidity in ripe cheese.

The influence of formaldehyde on proteids, R. STEINEGGER (*Landw. Jahrb. Schweiz, 19 (1905), No. 8, pp. 528, 529*).—In connection with the above investigations the author studied the influence of formaldehyde upon leucin and tyrosin, concluding that formaldehyde and other aldehydes are capable of entering into combinations with the amido bodies.

The possible infection of man with Micrococcus melitensis by goats' milk (*Jour. Roy. Army Med. Corps, 6 (1906), No. 1, pp. 113–116*).—An outbreak of Malta fever on shipboard is attributed, in the correspondence here given, to the drinking of the milk of goats.

On the injurious effects of sterilized milk on the nutrition of infants, A. KARAWJA (*Abs. in Chem. Ztg., 29 (1905), No. 94, Repert. No. 24, p. 353*).—The results of the author's investigations are unfavorable to the use of sterilized milk in infant feeding.

Principles and practice of butter making, G. L. MCKAY and C. LARSEN (*New York: John Wiley & Sons; London: Chapman & Hall (Ltd.), 1906, pp. XII+329, pls. 6, figs. 172*).—As the subtitle reads, this is a treatise on the chemical and physical properties of milk and its components, the handling of milk and cream, and the manufacture of butter therefrom.

The authors state that they have endeavored to incorporate the best and most progressive methods employed in butter making in the principal dairy countries of the world, and to give such related scientific information as may be of interest and value.

The scope of the treatise is indicated by the chapter headings, which are as follows: Composition of milk; milk secretion; properties of milk; ferments in milk; abnormal milk; variation of fat in milk; receiving, sampling, and grading milk and cream; composite samples; creamery calculations; heating milk previous to skimming; separation of cream; farm separators; pasteurization; cream ripening; starters; churning and washing butter; salting and working of butter; packing and marketing butter; composition of butter, and judging and grading butter. The book is well printed and illustrated.

Contribution to the knowledge and determination of volatile fatty acids in palm oils and butter, O. JENSEN (*Landw. Jahrb. Schweiz, 19 (1905), No. 8, pp. 477–495; Ann. Agr. Suisse, 6 (1905), No. 6, pp. 224–246; Rev. Gén. Lait, 4 (1905), No. 19, pp. 437–447; 20, pp. 457–464; 21, pp. 481–490; abs. in Jour. Soc. Chem. Indus., 24 (1905), No. 19, pp. 1025, 1026*).—The author separated the volatile fatty acids of cocoanut oil and butter by the fractional precipitation of their silver salts, and studied their properties.

Cocoanut oil was found to contain no butyric and but little caproic acids, while the percentages in butter, though varying greatly with different samples, were on an average 3.92 per cent for butyric and 1.88 per cent for caproic. For the detection of small quantities of cocoanut oil in butter the determination of caprylic and capric acids is recommended.

A marked case of late gassy fermentation in cheese, A. PETER and M. SCHNEEBELI (*Centbl. Bakt. [etc.], 2. Abt., 15 (1905), No. 19–20, pp. 600–605, pls. 2*).—From a series of 24 Emmenthal cheeses which showed gassy fermentation after 10 to 14 days the authors isolated a variety of *Bacterium lactis aerogenes* which was often present in nearly pure cultures and which was considered the probable cause of the trouble. A similar result was obtained in the manufacture of an experimental cheese in which this organism was used in a pure culture.

On the influence of lactic acid on casein and paracasein, O. LAXA (*Milchw. Zentbl., 1 (1905), No. 12, pp. 538–547*).—The author concludes from the results of his investigations that casein combines with lactic acid to form lactates.

The lactates which contain lactic acid up to 1 per cent are insoluble in water, while the lactates with higher acid contents are soluble in water. By dialysis a lactate may be obtained which contains from 1.4 to 1.9 per cent of lactic acid. By precipitation with mineral salt from a solution of casein in lactic acid a lactate may be obtained which contains 7.5 per cent of acid. It is, therefore, considered that the designation of the insoluble lactate as mono-lactate and the soluble lactate as di-lactate by Van Slyke and Hart (E. S. R., 14, p. 607) is unsatisfactory. [It may here be noted that the more recent investigations of Van Slyke and Hart (E. S. R., 16, p. 1018) have shown, according to these authors, that there is only one series of casein compounds formed by a combination with acids, and that what they previously supposed was a casein mono-salt was simply the base-free casein.]

Casein lactates contain only a small amount of phosphorus, 0.45 to 0.48 per cent. The spontaneous curdling of milk is explained by the formation of lactic acid by means of micro-organisms, the changing of the phosphates of milk into acid salts by means of the lactic acid, the formation in the milk of both soluble and insoluble lactates, and when the soluble lactates are present in sufficient quantities the precipitation of them by the mineral salts as curd. The high plasticity of the casein in cheese is due to the impregnation of the casein with calcium lactate. It is considered probable that paracasein is a combination of casein with calcium phosphates. By the influence of acids the paracasein is changed into casein and forms the same lactates as the casein.

New industrial product, R. GUENTHER (*Mo. Consular and Trade Rpts.* [*U. S.*] *1905, No. 302, p. 243*).—Brief reference is made to the manufacture of galalith, a horn-like product prepared from cows' milk, and stated to be valuable in the manufacture of various ornamental and useful articles.

Officials, associations, and educational institutions connected with the dairy interests of the United States for the year 1905 (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 80, pp. 12*).

VETERINARY MEDICINE.

Report of the Minnesota State Live Stock Sanitary Board, 1905, S. H. WARD ET AL. (*Ann. Rpt. Minn. Live Stock Sanit. Bd. 2* (*1905*), *pp. 119*).—Within recent years wheat has been less extensively planted in Minnesota than formerly, and animal industry has assumed greater importance. This statement is particularly true for dairying. The work of the live stock sanitary board has increased in value correspondingly.

Certain dairymen have raised objection to the inspection of cattle for tuberculosis and testing them with tuberculin. The test is not made compulsory, however, unless the disease is known to exist in the herd. On account of the fact that an indemnity is paid owners for the destruction of tuberculous cattle, it is recommended that such dairymen be not allowed to replenish their herd with other cattle without previous inspection. Otherwise the reimbursement for other animals would constitute a continual burden on the State.

Glanders appears most frequently in the counties adjacent to the Dakotas, and outbreaks are usually traced to the purchase of range horses. Considerable work has been done during the year on hog cholera, particularly with reference to the existence of a form of the disease caused by filterable virus, as described by the Bureau of Animal Industry of this Department. Notes are also given on swamp fever, rabies, and blackleg. W. L. Beebe presents a detailed report on the pathology and bacteriology of tissues and material sent to him during the year for examination.

Human and bovine tuberculosis, N. RAW (*Brit. Med. Jour., 1905, No. 2338, pp. 1018–1021*).—The views at present held by the author on the relationship between these two forms of tuberculosis are based on an observation of 3,500 cases of human tuberculosis and a study of 650 autopsies.

During these investigations it was found that the lungs of children may become infected by direct extension of infection from the mesenteric glands through the diaphragm to the lungs. This infection frequently follows the use of tuberculous milk. The author maintains that human and bovine tuberculosis are distinct diseases, and are capable of setting up different sets of symptoms at different periods of life, depending upon the localization of infection, and that primary intestinal tuberculosis is generally bovine in origin from infected milk. According to this view of the matter, therefore, human and bovine tubercle bacilli are distinct species, but man is susceptible to both.

The origin of pulmonary lesions in tuberculosis, H. VALLÉE (*Ann. Inst. Pasteur, 19* (*1905*), *No. 10, pp. 619–624*).—It appears to be established beyond controversy that in all species of animals the pulmonary parenchyma is the favorite tissue for the location of the tubercle bacillus.

In statistics collected on 43,000 animals the lungs were affected in 75 per cent of cases. The author inoculated 2 young calves by the intratracheal method and found that the lungs as well as the bronchial and mediastinal glands were difficult to infect in this way. Experiments were also carried out which seemed to indicate that the lungs may readily become affected by extension of an alimentary infection.

As a result of his investigations the author concludes that among the various methods of infection that of ingestion is calculated to produce most surely and most

quickly an infection of the lymphatic glands in the region of the lungs. The tubercle bacillus, introduced into the intestines, seems to be able to pass through the intestinal walls and the neighboring lymphatic glands without leaving any trace of its presence.

Intestinal origin of pulmonary tuberculosis, A. CALMETTE and C. GUÉRIN (*Ann. Inst. Pasteur, 19 (1905), No. 10, pp. 601–618*).—The investigations reported in this paper were undertaken for the purpose of obtaining information regarding the proposition of von Behring that pulmonary tuberculosis usually arises as the result of intestinal infection in early life. For this purpose the authors experimented with goats, testing the effect upon this animal of ingestion of tuberculous products of various origin.

It was found possible to infect the mammary gland of goats with cultures of bovine, human, and avian tubercle bacilli as well as with those of pseudotuberculosis. Even when the tissue of the gland was in no way injured, cultures of bovine tubercle bacilli introduced into it led to the death of the animal within a short time and without extension of the lesions to any other organ. Cultures of human tubercle bacilli, however, were less virulent and produced lesions which slowly healed. The avian bacillus and the bacillus of pseudotuberculosis were less virulent.

Young goats were then allowed to suck milk from mammary glands infected in the manner just described. From these experiments it appears that young goats react in a decided manner to any of the cultures already mentioned obtained in the milk of infected goats. The reaction was most pronounced in the mesenteric glands. In all cases, without regard to the kind of bacillus, these glands became greatly swollen, but only the bovine and human tubercle bacilli led to the actual formation of tubercles within the ganglia. The bovine bacillus caused the most serious infection, leading to caseation of the tubercles and ultimately extending to the lungs. After infection with the human bacilli, however, the lesions tended to heal by calcification.

Detailed notes are given on the post-mortem findings in young goats treated in the manner indicated. Cultures of the same species of bacilli were then introduced by means of a sound directly into the rumen of other young goats. In these experiments also the bovine bacillus was most virulent, producing secondarily a pulmonary infection. Human bacilli appeared to be harmless for young goats when introduced directly into the rumen and did not exercise a vaccinating effect toward bovine bacilli. Avian bacilli and bacillus of pseudotuberculosis were equally harmless.

In the first experiments carried out by the authors, an apparent confirmation of von Behring's theory was found. Later, however, experiments showed that von Behring's theory that pulmonary tuberculosis of the adult results from a slow development of an intestinal infection in early life is probably wrong. According to the authors' experiments in adult goats, the infection proceeds more easily from the intestines to the lungs than in early life.

Danger of infection with tuberculosis by different kinds of exposure, E. C. SCHROEDER and W. E. COTTON (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 44–65*).—In determining the relative liability of infection from different methods of exposure the authors subjected guinea pigs to infection from abdominal injections of milk from tuberculous cows, from feeding tuberculous milk, being confined in cages on the walls of stalls in which tuberculous cattle were kept, or in the mangers of such cattle.

The milk used for intraabdominal injections came from 6 tuberculous cows, and 224 guinea pigs received injections of such milk. Of this number 4, or 1.78 per cent, became infected. The total amount of milk used in these injections was about 3 pts. The number of guinea pigs fed tuberculous milk was 132, and of this number 1, or 0.76 per cent, became infected. The total amount of milk fed was about 118 gal. and the average feeding period about 47 days. The number of guinea pigs exposed in the same stall with tuberculous cows was 35, and of this number 2, or

5.71 per cent, became tuberculous after an average exposure of 135 days. During the same time 42 guinea pigs were exposed in the mangers of the same cows, and of this number 6, or 14.28 per cent, were infected.

A series of experiments was also carried out on 19 hogs, which were fed in all 462½ gal. of tuberculous milk during an average feeding period of 143 days. None of the pigs became infected.

Comparing intraabdominal injections of tuberculous milk with ingestion of the same product, it was found that the latter method required 12,000 times as much milk as the former to produce an infection These experiments are believed to show that while the milk of tuberculous cows is a dangerous product, the liability to infection from it is much less than from other sources of infection. Attention is called to the fact that not one of the 132 guinea pigs injected with milk from one of the cows which was badly affected with tuberculosis developed the disease.

Clinical and bacteriological diagnosis of bovine tuberculosis, J. VENNERHOLM (*Svensk Vet. Tidskr., 10 (1905), No. 11, pp. 444–451*).—Particular attention is given in this review to a consideration of the investigations of Ostertag and his associates on the means of diagnosing various forms of tuberculosis, especially mammary tuberculosis.

The tuberculin test for tuberculosis, D. E. SALMON (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 79, pp. 14*).—This circular is a reprint from the Yearbook of the Department for 1901 (E. S. R., 14, p. 396).

Vaccination against tuberculosis, THOMASSEN (*Tijdschr. Veeartsenijk., 33 (1905), No. 3, pp. 151–162*).—The literature relating to this subject is briefly discussed.

The author experimented with young calves to determine suitable methods of immunizing them against tuberculosis. For this purpose cultures of human tubercle bacilli, serum from hyperimmunized cattle, tuberculin, and bovovaccine of von Behring were tested. As a result of the author's experiments it is concluded that active immunity toward tuberculosis may be brought about in young calves.

The author recommends that calves should be vaccinated at the age of about six weeks before exposure to tuberculosis and only after a negative result from tuberculin test. The use of human tubercle bacilli of low virulence is preferred to that of other vaccines or serums. Special care is urged in pulverizing the bacilli in order to prevent possible pulmonary lesions in the young calves. The degree of immunity is not definitely determined. The author believes that the method will suffer from certain practical difficulties when applied on a large scale.

The development of tubercular mammitis, G. MOUSSU (*Rec. Méd. Vét., 83 (1905), No. 23, pp. 777–788, pls. 2, figs. 2*).—Attention is called to the fact that the large percentage of tuberculosis observed in hogs fed on dairy by-products around creameries and cheese factories has been greatly reduced as the direct result of sterilizing these products.

The author insists that it is not sufficient to regard the milk merely from cows affected with tuberculosis of the udder as infectious. From his own observations combined with those of others he believes that the milk of all tuberculous cows must be considered as dangerous. It is granted that frequently, perhaps in the majority of cases, the milk of tuberculous cows in which the udder is not affected does not contain enough tubercle bacilli to produce infection. The fact can not be determined, however, from an external examination of the cow, and the milk is, therefore, to be suspected.

In order to prevent the distribution of tuberculosis by means of tuberculous milk, it is recommended that all tuberculous cows be excluded from herds which furnish milk for the public. On account of the difficulty of carrying out such measures at once it is recommended that temporarily the milk of tuberculous cows be sterilized or otherwise treated so as to destroy the tubercle bacillus before distributing for use.

Contagious mammitis, G. MAYALL (*Vet. Rec., 18 (1905), No. 910, p. 414*).—In

cases of contagious mammitis the author reports good success from the use of an ointment consisting of equal parts of lanolin and lard mixed with ½ dr. each of calomel and carbolic acid for every 2 oz. of the base. The external lesions in bad cases of contagious mammitis are perhaps irritated to considerable extent by milking. The use of a milking siphon, however, in such cases seems to be a doubtful procedure, for the reason that the infection might be thereby spread.

Abortion and sterility in cows, J. A. GILRUTH (*Jour. Dept. Agr. So. Aust., 9 (1905), No. 4, pp. 255–261*).—These diseases, though usually separated, are in reality closely associated and cause great losses annually in South Australia.

The symptoms and means of dissemination of this disease are described. The method of procedure in treating cows consists in the free use of antiseptics. During the past 3 years several thousand cows have been treated with antiseptic washes of corrosive sublimate and almost uniformly the results have been satisfactory.

Hemorrhagic enteritis of cattle, CHAUSSE (*Rec. Méd. Vét., 83 (1905), No. 23, pp. 788–795*).—From the accounts of various investigators relating to this disease it appears that it is not always due to the same cause. The various forms of the disease are briefly described and notes are given on the pathological lesions. No satisfactory treatment has been devised. In a few cases hypodermic injections of ergotine in doses of 0.5 to 3 gm. daily have proved efficacious.

Contagious conjunctivitis of cattle, F. A. VERNEY (*Natal Agr. Jour. and Min. Rec., 8 (1905), No. 11, pp. 1079, 1080*).—This disease usually affects young calves, but sometimes occurs among adult animals. The symptoms are briefly described. It is evidently contagious, and diseased animals should, therefore, be quarantined. As a direct treatment for the eye, the author recommends a solution of nitrate of silver and extract of belladonna containing 8 grains each to an ounce of water.

Contagious pleuro-pneumonia, D. HUTCHEON (*Agr. Jour. Cape Good Hope, 27 (1905), No. 6, pp. 756–773*).—According to the observations of the author the period of incubation of the disease ranges from 42 to 59 days, and death occurs within from 17 to 33 days after the disease appears.

The symptoms and post-mortem lesions are described in detail. In securing virus for use in preventive inoculation an animal in the first stages of the disease should be selected and killed. The pleural fluid may then be removed under aseptic conditions and used for inoculation of healthy animals. Inoculation does not always render animals immune. In some cases the vaccine does not appear to take.

The author found that the pleural fluid could also be used successfully in preventing the disease when applied as a drench. In this operation the fluid should be collected in a careful manner and strained, after which it is given as a drench without the addition of water. Care should be exercised not to cause any abrasion of the mucous membranes during the operation, since otherwise a fatal infection may take place.

Experiments with septicidin in septic pleuro-pneumonia of calves, EBERHARD (*Berlin. Tierärztl. Wchnschr., 1905, No. 49, pp. 829, 830*).—On account of the prevalence of this disease and the difficulty of eradicating it by ordinary means, the author tested septicidin for this purpose.

During one outbreak of the disease the author vaccinated 15 calves. Each calf received 10 cc. of the septicidin hypodermically. None of the vaccinated calves became infected. The same remedy was tested on another estate with equally satisfactory results. It was not used for curative purposes.

Epizootic lymphangitis, S. T. AMOS (*Natal Agr. Jour. and Min. Rec., 8 (1905), No. 10, pp. 993–996, pl. 1*).—Infection from this disease usually takes place through skin wounds chiefly on the ribs and flank, but also on the fore limbs.

The post-mortem appearances of the disease are described and notes are given on the treatment. In cases which have been allowed to run for a long time without

care there is no hope of cure. In the early stages, however, a recovery may be brought about by the application of an ointment of biniodid of mercury.

Bacillus necrophorus and its economic importance, J. R. MOHLER and G. B. MORSE (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 76-116*).—An elaborate review is presented of the synonymy, history, and literature of this bacillus in connection with the bibliography of related articles.

The organism occurs normally in the intestines of hogs and perhaps also of the cow and horse. Notes are given on its morphology, motility, staining, biology, behavior on different culture media, and chemical activities. It is destroyed by exposure to a 2 per cent solution of carbolic acid for 2 minutes, a 1/2000 solution of bichlorid of mercury for 9 minutes, or a 1 per cent formaldehyde solution for 13 minutes. The authors described in detail the pathogenic properties of this organism and the special pathology as shown in cases of necrobacillosis of the skin in rabbits, guinea pigs, and other animals, and also in the hoof and digestive tract.

An account is also presented of other diseases caused by the necrosis bacillus, such as necrotic stomatitis, ulcerative anovulvitis, necrotic vaginitis, necrotic metritis, foot rot of cattle and sheep, joint ill, avian diphtheria, etc. The deep ulcers in the intestines in cases of hog cholera are apparently due to the necrosis bacillus, and the organism has also been isolated from chickens affected with diphtheritic roup as well as other birds. As a prevention against this organism the authors recommend the thorough application of antiseptics.

Poisoning of cattle by molds, BAYER (*Wchnschr. Tierheilk. u. Viehzucht, 49 (1905), No. 50, pp. 793, 794*).—The author presents some of the details of symptoms and pathological lesions observed in 5 cattle which were affected by eating clover badly damaged by certain common molds, especially *Aspergillus glaucus* and *Penicillium glaucum*. The symptoms were great weakness, reddened mucous membrane of the mouth, loss of appetite, paralysis of the throat, and diarrhea.

Enzyms in cornstalks and their relation to cornstalk disease, T. M. PRICE (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 66-75*).—On account of the suddenness with which death occurs in many cases of so-called cornstalk disease, it was suspected that the presence of prussic acid in cornstalks might be the cause.

Cornstalks were obtained from a field where a number of cattle had died of cornstalk disease, but upon direct analysis for prussic acid this poison could not be determined. Negative results were also obtained from an attempt to find a glucoside which might break up into prussic acid. Attention was then directed to the possible presence of enzyms, and a peroxydase was found with the properties of catalase. Further analyses showed that neither diastase, invertase, lactase, maltase, cytase, or lipase were present. The cornstalk enzym lost its power of splitting up glucoside when subjected to a temperature of 78° C. The proteolytic enzym was broken up at 68° C. The cornstalk enzym appeared to have the same resisting power toward heat as that obtained from bitter almonds.

The author believes that these investigations, while not conclusive, indicate the presence of an enzym in cornstalks which may give rise to the formation of prussic acid by splitting up glucosides. This would account for a certain percentage at least of the cases of cornstalk disease.

A recent outbreak of sheep pox, TEETZ (*Berlin. Tierärztl. Wchnschr., 1905, No. 49, p. 830*).—In outbreaks of this disease it is recommended that a strict quarantine be enforced, so that healthy animals may not be exposed to the disease. When quarantine is maintained with sufficient stringency it is possible to make incisions in the swollen parts of the skin in infected sheep and treat the wounds so that the mortality is reduced to a very low percentage.

Report of the work against scabies of sheep and cattle in 1904, C. O. GOODPASTURE (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 447-460*).—During

the year under report there has been a decided reduction in the number of scabby sheep received at the principal market centers, and this reduction is attributed to the greater restrictions on the traffic of sheep without inspection.

The number of scabby sheep received at regular stations in 1904 was 85,221. During the same year the total number of sheep inspected was 43,000,000, of which 3,000,000, or 7.4 per cent, were infected. The total number of sheep dipped was more than 12,000,000, of which 2,000,000 were dipped the second time. The percentage of effectiveness was 99.35. Special attention is called to the very successful work in the eradication of sheep scab in Utah and Wyoming, where the results are largely due to the thorough and satisfactory cooperation between the State and Federal authorities. Such cooperation has also been arranged in New Mexico and other infected districts.

The woolgrowers of the Western States have come to realize the importance of drastic measures in dealing with sheep scab. During the year 1904 the number of scabby cattle received at regular market centers was 19,702. The total number of cattle inspected during the same year was 8,395,000, of which 230,000 were scabby. The total number of cattle dipped during the year was 564,000, including 169,000 which were dipped twice.

Hog cholera, W. ROBERTSON (*Agr. Jour. Cape Good Hope, 27 (1905), No. 6, pp. 735–746, pls. 2*).—The history of this disease in South Africa is outlined in considerable detail, and notes are given on the symptoms and post-mortem lesions, especially as observed by the author in South Africa.

In general, the pulmonary lesions appear to be quite constant and occur independently of the intestinal ulcers. Directions are given for disinfecting premises after the occurrence of the disease, and on other methods for preventing the disease by means of quarantine and isolation of affected hogs.

The use of mallein in diagnosing glanders, L. J. HOOGKAMER and J. DE HAAN (*Tijdschr. Veeartsenijk, 33 (1905), No. 3, pp. 169, 170*).—As a result of extensive mallein tests carried out since 1896 the authors conclude that glanderous horses should ordinarily show a reaction of 1½ to 2° C. after inoculation with mallein. The temperature of healthy horses should not rise above 38.4° C. after inoculation.

Dog distemper, PIORKOWSKI (*Berlin. Tierärztl. Wchnschr., 1905, No. 49, pp. 830–832*).—Much attention has been given to a study of the bacteriology of this disease.

The author isolated several bacteria from cases of dog distemper and finally found a virulent organism in the spleen, lungs, and hypophysis of the brain. This organism in pure cultures produced death from typical dog distemper within 2 to 3 weeks after the inoculation of healthy dogs. From this organism a serum was obtained through culture and inoculation experiments which produced satisfactory results in 83 per cent of cases. The author believes, therefore, that this serum may be relied upon in preventing the development of dog distemper.

Fowl cholera, C. H. STANGE (*Iowa Agr., 6 (1905), No. 3, pp. 86–88*).—The symptoms of this disease are briefly described.

Since treatment is ordinarily ineffective, it is necessary to adopt preventive measures. To this end poultry houses in which an outbreak of the disease has occurred should be treated with carbolic acid or some other antiseptic, and dead or diseased fowls should be disposed of by burning or burying deeply. In order to prevent the spread of infection to healthy fowls, corrosive sublimate may be placed in the drinking water at the rate of 1 part in 2,000.

Animal parasites affecting domesticated animals, DESMOND (*Jour. Dept. Agr. So. Aust., 9 (1905), No. 4, pp. 247–255, figs. 9*).—Notes are given on certain tapeworms which infest horses, including *Tænia perfoliata*, *T. plicata*, and *T. mamillana*.

In preventing infestation by these parasites attention should be given to the water supply, since horses may become infested from contaminated water. The water may be treated with sulphate of iron. Santonine and tartar emetic may be

added to the food. A peculiar case of intestinal infestation in a horse is reported. The larvæ of botflies were found attached in considerable numbers to *Ascaris megalocephala* and tapeworms in the intestines of the horse.

Treatment for worms in domestic animals, D. HUTCHEON (*Agr. Jour. Cape Good Hope, 27 (1905), No. 5, pp. 589–614, figs. 20*).—Particular attention is given to treatment of domesticated animals for tapeworms, roundworms in horses, and stomach worms of sheep.

Sulphate of copper is said to be one of the longest used and most effective remedies for roundworms in horses. It also gives good results in the treatment of stomach worms in sheep and tapeworms in calves, lambs, and kids. During experiments in drenching animals with a solution of sulphate of copper, it was found that goats were more resistant to this drug than sheep. Goats were given as much as 40 grains sulphate of copper and 4 oz. of water without harm, no inflammation being caused in the mucous membrane of the stomach. In the preliminary experiments with sulphate of copper in treating lambs, however, numerous cases of the poisonous effects of this substance were seen and many deaths were caused.

After further experimentation it was decided that copper sulphate to be used for such work should be of standard purity of a uniform dark blue color. It appears that a fast of more than 30 hours renders sheep more susceptible to the influence of copper sulphate than they otherwise would be. The author recommends that 1 lb. of copper sulphate be dissolved in 10 gal. of water, and that from this solution 1½, 3, 3½, 4, and 5 oz., respectively, be fed to lambs 3, 6, 9, 12, and 18 months old.

Numerous experiments were carried out in treating ostriches for infestation with *Srtongylus douglassii*. As a result of these experiments it was found that a preliminary dose of kerosene oil tends to remove gastric mucus caused by the presence of parasitic worms. The parasites are then more directly exposed to the action of carbolic acid and turpentine, which are recommended in destroying these worms. The method of procedure recommended by the author is as follows: After fasting 18 hours give 12 oz. of kerosene and an equal quantity of milk to adult birds. After 2 or 3 days allow the birds to fast again for 18 hours, after which they are to be given 4 dm. carbolic acid and 12 dm. of turpentine in 10 oz. of water.

The tapeworms of American chickens and turkeys, B. H. RANSOM (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 268–285, figs. 31*).—In this article the author presents complete descriptions of all species of tapeworms known to occur in chickens and turkeys in the United States. A key is also given to assist in their identification and brief notes are presented on the life history of the tapeworm and means of eradicating them.

Contagious diseases of animals in foreign countries, J. ROBERTS (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 461–468*).—Statistics are presented on the extent of the more important infectious diseases in Belgium, Denmark, France, Germany, Great Britain, Hungary, Netherlands, Norway, and Sweden.

The exhibit of the Bureau of Animal Industry at the Louisiana Purchase Exposition, J. M. PICKENS and J. W. FINK (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 406–416, pls. 2*).—A brief account is presented of the exhibit made by the Bureau at the St. Louis Fair with particular reference to meat inspection, stock inspection, discussion of animal diseases, horseshoeing, dairy industry, and animal husbandry.

RURAL ENGINEERING.

Report of irrigation and drainage investigations, 1904 (*U. S. Dept. Agr., Office Expt. Stas. Bul. 158, pp. 755, pls. 12, figs. 129*).—This is the fifth annual report of the investigations in these lines carried on by this Office.

The report contains the following articles: Review of the Irrigation Work of the Year, by R. P. Teele; Irrigation in Santa Clara Valley, California, by S. Fortier;

The Distribution and Use of Water in Modesto and Turlock Irrigation Districts, California, by Frank Adams; Relation of Irrigation to Yield, Size, Quality, and Commercial Suitability of Fruits, by E. J. Wickson; Irrigation Conditions in Imperial Valley, California, by J. E. Roadhouse; Mechanical Tests of Pumps and Pumping Plants used for Irrigation, by J. N. Le Conte; Irrigation in Klamath County, Oregon, by F. L. Kent; Irrigation Investigations in Yakima Valley, Washington, 1904, by O. L. Waller; Irrigation Conditions in Raft River Water District, Idaho, 1904, by W. F. Bartlett; Irrigation Investigations at New Mexico Experiment Station, Mesilla Park, 1904, by J. J. Vernon; Irrigation Investigations in Western Texas, by Harvey Culbertson; Pumping Plants in Texas, by C. E. Tait; Irrigation in Southern Texas, by A. J. Bowie; Rice Irrigation in Louisiana and Texas in 1903 and 1904, by W. B. Gregory; Rice Irrigation on the Prairie Land of Arkansas, by C. E. Tait; Irrigation Experiments at Fort Hays, Kansas, 1903 and 1904, by J. G. Haney; Irrigation near Garden City, Kansas, 1904, by A. E. Wright and A. B. Collins; Pumping Plants in Colorado, Nebraska, and Kansas, by O. V. P. Stout; Irrigation near Rockyford, Colorado, 1904, by A. E. Wright; The Irrigation and Drainage of Cranberry Marshes in Wisconsin, by A. R. Whitson; and Report of Drainage Investigations, 1904, by C. G. Elliott.

A leading line of work has been the collection of information regarding the duty of water. This has included the measurement of the water at the heads of main canals where they leave the streams, at the heads of laterals from main canals, and at the margins of fields where the water is actually applied to the crops. The differences in the quantities found at these different points represent approximately the losses of water in transit. The average depth to which the water measured would cover the land irrigated was found to be as follows: Main canals 5.13 ft., laterals 4.03 ft., farms 3.07 ft.

In addition to these measurements of the quantities of water used in common practice, experiments were made to determine the results of applying the water at different stages of the crop's growth. These experiments look to a more scientific use of water in irrigation, and if possible a more economical use. The experiments indicate that the largest product from the use of given quantities of water and the largest product per acre do not coincide.

At the New Mexico Station it was found that the largest product per acre inch of water was secured when the depth of water applied was 24 in., but the largest product per acre was secured with a depth of 35 in. These experiments have not been extended far enough to give any definite conclusions as yet.

Experiments have also been made in increasing the duty of water by lessening the losses in apylying it to crops. Experiments in California in applying water by flooding in shallow furrows and in deep furrows showed comparative losses as follows, taking the loss in flooding as 100 per cent: Flooding, 100 per cent; furrows 3 in. deep, 87 per cent; furrows 12 in. deep, 75 per cent.

A large number of measurements of the losses from canals by seepage and evaporation are reported. A general average of all of these measurements gives 6.76 per cent of the water entering the headgates of canals lost per mile of length, the losses varying from almost nothing to almost 100 per cent. The measurements show, however, a large decrease in the percentage of loss with increase in the size of the canals. Averaging all of the measurements according to the sizes of canals gives the results shown in the following table:

Losses of water from canals by seepage and evaporation.

	Percentage loss per mile.
13 canals carrying 100 cu. ft. per second or more	0.95
15 canals carrying between 50 and 100 cu. ft. per second	2.58
15 canals carrying between 25 and 50 cu. ft. per second	4.21
24 canals carrying less than 25 cu. ft. per second	11.28

The water escaping from canals is not, however, all lost, as is shown by the measurements of return seepage reported. A large number of measurements of the gain in the flow of the South Platte and its tributaries is summarized. The measurements on the South Platte itself are divided into two groups, representing 7-year periods, showing a large increase in the rate of gain in the second period over that in the first.

A series of measurements made in 1903 show the gain of 727.61 cu. ft. per second in the flow of the river in 232.75 miles, or 3.3 cu. ft. per second per mile throughout the course of the stream. Measurements for the months of July and August, 1903, show gains between the mouth of the canyon of the South Platte and the Colorado-Nebraska line of 307 and 344 per cent, respectively. Similar measurements for a large number of other streams are given.

The cost of preparing land for irrigation, including removing sagebrush, smoothing or leveling land, and building laterals is given as ranging from $3.50 to $35 per acre, varying with the original condition of the land.

A large part of the report is devoted to pumping investigations throughout the arid and semiarid regions. The summary of results shows that the pumps tested gave an average efficiency of 41.17 per cent, while the fuel cost of raising water varied from 1.6 to 25.3 cts. per foot-acre-foot, the larger cost being for plants requiring less than 1 horsepower, and the smaller cost for large steam plants, using cheap crude oil for fuel. The descriptions of the plants in use are of great value for bringing out the good points as well as those which should be avoided.

The average annual cost of raising water with windmills, including interest on the investment, is given as $9.50 per acre. From this high cost the conclusion is drawn that windmill pumping, except for the irrigation of high-priced crops, will not be found profitable.

The drainage work reported on includes the reclamation of swamp and alkali lands in the arid region, the protection of bottom lands from overflow, the drainage of farm lands, and protection of hillsides from erosion by means of underground drains. The methods of laying out and constructing drains for all of these purposes are discussed and the results obtained are given.

Duty of water, B. P. Fleming (*Wyoming Sta. Bul. 67, pp. 20*).—This bulletin contains summaries of all of the measurements of duty of water made by the Wyoming Station from 1893 to 1903.

The average depth of water applied to different crops per year at the station during that period was as follows: Alfalfa 1.97 ft., barley 1.53 ft., oats 1.73 ft., and wheat 1.62 ft. Concerning the length of the irrigation season for these crops the conclusion is that a water supply should be available from June 1 to September 15.

In addition to measurements of the quantity of water used in general practice, experiments have been carried on to determine the relation between the quantity of water applied and the yield. These experiments have included potatoes and oats. Potatoes yielded the largest return per acre when receiving water to a depth of 16.29 in. and oats with 43.59 in. The largest returns per inch of water applied were with potatoes 16.29, and with oats 16.59.

These measurements show that with oats at least the largest return per unit quantity of water does not coincide with the largest return per acre. "Consequently when a man has a large area of land and a small water supply he will probably find that he will be making the best use of his available supply when he spreads that amount over a larger area than it is the common practice to do."

The Winterton Irrigation Settlement (*Notes on Agriculture in Natal, Maritzburg: Dept. Agr., 1905, pp. 9–20*).—In 1904 the agricultural development act was passed for the purpose of securing rural settlement in Natal. A board was created which is authorized to make loans to settlers, limited to £60 for the first year, for the purchase of live stock, implements, food, etc., to be repaid in 3 years and bearing 4½ per cent interest.

A dam has been built and a canal 18½ miles long which will irrigate 17,940 acres. This area is divided into three classes—first class land fit for special crops, second class land fit for mixed farming, and third class land fit only for grazing. This is to be leased to settlers in tracts varying from 250 to 500 acres according to its classification. Settlers are advised that they will need capital of at least £250. The article contains information as to the necessary expenditures and probable returns from farming operations.

Diagrams of mean velocity of uniform motion of water in open channels; based on the formula of Ganguillet and Kutter, I. P. CHURCH (*New York: John Wiley & Sons, 1902, pls. 11, desc. text*).—This set of diagrams was prepared for the purpose of determining the mean velocity in open channels instead of computing it in each case from Kutter's formula.

There is one diagram for each of eleven different values of "n," or the coefficient of roughness, ranging from 0.009 to 0.035, and ranging from 0.1 to 25 ft. in values of R, the hydraulic radius, and for slopes varying from 0.01 ft. per thousand to 100 ft. per thousand, that is, values of S varying from 0.00001 to 0.100. This is sufficient range to cover the ordinary cases.

The coefficients of roughness for channels of various kinds are given as follows:

0.009, for well-planed timber evenly laid.

.010, plaster in pure cement; glazed surfaces in good order.

.011, plaster in cement with one-third sand; iron and cement pipes in good order and well laid.

.012, unplaned timber, evenly laid and continuous.

.013, ashlar masonry and well-laid brickwork; also the above categories when not in good condition nor well laid.

.015, "canvas lining on frames;" brickwork of rough surface; foul iron pipes; badly jointed cement pipes.

.017, rubble in plaster or cement in good order; inferior brickwork; tuberculated iron pipes; very fine and rammed gravel.

.020, canals in very firm gravel; rubble in inferior condition; earth of even surface.

.025, canals and rivers in perfect order and regimen and perfectly free from stones and weeds.

.030, canals and rivers in earth in moderately good order and regimen, having stones and weeds occasionally.

.035, canals and rivers in bad order and regimen, overgrown with vegetation, and strewn with stones and detritus.

Proceedings of the second annual Iowa State Drainage Convention (*Proc. Iowa State Drainage Conv., 2 (1905), pp. 65, figs. 7*).—This report contains the minutes of the meetings and the following papers: Appraisement of Damages and Assessments of Benefits in Drainage Work, by C. G. Elliott; The New Iowa Drainage Law, by R. M. Wright; The Importance of Drainage in Good Roads Construction, by A. Marston; President's Address, by D. A. Kent; The Drainage of Meandered Lakes, by L. E. Ashbaugh; Progress in Drainage Improvements during 1904, by J. F. Ford; The Relation of the Soil to Underdrainage, by W. H. Stevenson.

Proceedings of second conference of engineers of the Reclamation Service, with accompanying papers, F. H. NEWELL (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 146, pp. 267*).—The papers included deal with water laws, hydrography, power engineering in irrigation, tunneling, field and office accounts, pumping, diamond drilling, stream gaging, computations, aquatic plants, camp sanitation, drainage, silting of reservoirs, flow under ice, and a few reports of particular projects.

A number of committee reports of general interest on concrete, cost-keeping, duty of water, and pumping are added, and others of a more special kind relating to standard specifications, forms of reports, etc., of interest to members of the Reclamation

Service. There is appended a partial directory of members, with records of their training and experience, and a list of technical papers by engineers in the Reclamation Service.

Development of underground waters in the Eastern Coastal Plain Region of southern California, W. C. MENDENHALL (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 137, pp. 140, pls. 7, figs. 6*).—A brief history of the irrigation companies diverting water from streams is first presented, with brief notes on drainage districts. The source of underground water supply is then discussed, data being given to show that the draft by pumping has materially decreased the former artesian area. Five maps are presented, showing present and past artesian areas, hydrographic contours, irrigated lands, canals, location of wells, and the usual topographic and other data. The larger part of the paper consists in a list of nearly 2,800 wells, giving owners, location, description, depth, and water elevation, solids in solution, temperature, method of lift, cost of well and machinery, use of water, and estimated discharge.

The same method of treatment is followed in the second and third of this series, dealing with the Central Coastal Plain Region of Southern California (Water-Supply and Irrig. Paper No. 138, pp. 162, pls. 5, figs. 5) and Western Coastal Plain Region of Southern California (Water-Supply and Irrig. Paper No. 139, pp. 105, pls. 8, fig. 1).

Observations on the ground waters of Rio Grande Valley, C. S. SLICHTER (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 141, pp. 83 + III, pls. 5, figs. 32*).—An investigation of the underflow of Rio Grande near El Paso, which was popularly supposed to be enormous, showed a probable flow of only 50 gals. per minute, the water being too salt for any use whatever.

Data regarding the supply below El Paso and in Mesilla Valley are presented, showing the small amount of water contributed by the river. A detailed study of 18 pumping plants is given, with cost data, which shows a variation in cost of water delivered of from $2.21 to $13.20 per acre-foot, the fuel cost varying even more—from $0.70 to $5.80 per acre-foot. In eight cases the wells are lowered over 20 ft. by pumping, usually indicating too large power for the capacity of the well. Larger strainers and deeper wells are recommended.

Analyses of water samples from El Paso are given in an appendix.

The hydrology of San Bernardino Valley, California, W. C. MENDENHALL (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 142, pp. 124, pls. 12, figs. 16*).—"This report is one of a series on the underground waters of southern California. In this valley, where irrigation practice has attained a high degree of perfection, the underground waters are of very great importance, two-thirds of the irrigated acreage being dependent upon them either wholly or in part. The author has had in mind the practical irrigator and questions which arise concerning title to percolating waters."

After a preliminary discussion of the valley, its settlement, irrigation development, rainfall, soil, and runoff, the author devotes about 40 pages to a treatment of San Bernardino artesian area, its geology, water supply, and particularly the decline of the waters in the past ten years. The conclusion is reached that "it is obviously unwise to increase present drafts upon the basin," and that better methods in irrigation practice and a "fully supported policy of forest conservation and restoration are essential."

Yucaipe and Riverside basins are also briefly discussed, and miscellaneous data on temperature, water analyses, and stream and canal gagings are given. A list of about 500 wells, with depth, cost, and other data is given.

Wells, M. RINGELMANN (*Jour. Agr. Prat., n. ser., 9 (1905), No. 23, pp. 734–736, figs. 6*).—A cheap portable machine for driving wells by hand, with notes on its use.

Windmills, M. Ringelmann (*Jour. Agr. Prat., n. ser., 10 (1905), No. 42, pp. 496–500, figs. 4*).—A description of some American and European mills with a discussion of the pressure of wind and methods of regulating mills.

Experiments on steel-concrete pipes on a working scale, J. H. Quinton (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 143, pp. 61, pls. 4, figs. 4*).—Seven 20-ft. sections of pipe of 5 ft. inside diameter and 6 in. thick, reenforced with welded steel rings, were made, using various proportions of cement, sand, and gravel. These were coated inside with different plasters and paints and tested with all heads up to 140 ft. It was found impossible under moderate heads to prevent sweating through every coating tried and serious leakage through tamping seams under heads of over 60 ft.

To avoid the inequalities incident to continuous pipe, a section of four 5-ft. segments was made and tested with various coatings. Further tests were made on pipes of 8 in. inside diameter. The writer concludes that extreme care is essential in mixing and tamping; that paints are too thin and soap-and-alum mixtures not wholly satisfactory, and that heads of over 70 ft. are not practicable. No cost data are given.

Cement mortar and concrete: Preparation and use for farm purposes, P. L. Wormeley, Jr. (*U. S. Dept. Agr., Farmers' Bul. 235, pp. 32, figs. 14*).—This bulletin describes in a very elementary way the proper method of mixing and handling concrete.

The use of different materials for making concrete is explained, and detailed directions are given for making sidewalks, basement floors, steps, and fence posts. In an appendix are given results of some tests on concrete fence posts, tests showing the effect of retempering Portland-cement mortar, and a diagram showing the effect of clay on cement mortars.

Trap rocks of Palouse region as road material, C. N. Little and W. G. Turley (*Idaho Sta. Bul. 50, pp. 16, figs. 2*).—Abrasion and cementation tests of 13 samples with notes on methods employed and comparative tests of 3 samples made in the laboratories of this Department.

The good roads problem in Iowa, A. Marston, C. F. Curtiss, and T. H. MacDonald (*Iowa Engin. Sta. Bul., 2 (1905), No. 6, pp. 24, pls. 12, figs. 5*).—This bulletin contains a copy of the law creating the Iowa State Highway Commission, a general discussion of the State with regard to its road conditions and road materials, and brief notes as to methods of road construction and maintenance.

Third annual report of the State board of public roads, Rhode Island (*Ann. Rpt. Bd. Pub. Roads R. I., 3 (1905), pp. 39, pls. 47, fig. 1*).—A general discussion is given of the advantages of good roads and the necessity of prompt repairs on macadamized roads.

During 1904, 16.3 miles of stone roadways were contracted for at an average cost of $4,953.05 per mile. In all cases where roads have been improved grades have been reduced. The methods of testing stone as road material in this Department are described and a table showing the road-making value of Rhode Island material is given. A copy of the standard specifications for stone roadways is also given. The report contains a large number of companion pictures showing roadways before and after improvement.

Eighth annual report of the commissioner of highways, Ontario, 1903 (*Ann. Rpt. Comr. Highways Ontario, 8 (1903), pp. 102, pl. 1, figs. 25, dgms. 3*).—This report deals principally with defects of employing statute labor on highways in the Province of Ontario, and the advantages to be gained by commutation of this labor and expenditure of the funds thus acquired under the direction of expert roadmakers.

A tabular statement is given showing the counties in which commutation is provided for, and the rates allowed, which vary from 50 cts. to $1 per day. There is also given a tabular statement of the road expenditures by counties for the years

1889–1901. The report gives directions for all classes of road work, including grading, building culverts, and wooden, steel, and reenforced concrete bridges.

Hydraulic motors, I. P. CHURCH (*New York: John Wiley & Sons, 1905, pp. IX+269, figs. 125, dgms. 7*).—This book includes both the theory and descriptions of water wheels, impulse wheels, turbines, centrifugal pumps, pressure engines, accumulators, and hydraulic rams. It represents the most modern treatment of these important lines of machinery.

A brief discussion is also given of flow in pipes and open channels and backwater due to weirs. An appendix contains graphic conversion scales, diagrams showing friction head loss and discharge of cast-iron and wrought-iron pipe for various velocities, diagrams of Kutter's formula, four-place logarithms, and three-place trigonometric functions.

A steam traction engine, R. DESSAISAIX (*Jour. Agr. Prat., n. ser., 9 (1905), No. 24, pp. 774, 775, fig. 1*).—An improved English engine, with large heating area, and adapted to burning wood and refuse.

Methods of testing farm machines, A. NACHTWEH (*Fühling's Landw. Ztg., 54 (1905), Nos. 19, pp. 663–667, figs. 3; 22, pp. 769–775, figs. 5*).—A description of a recording dynamometer for farm vehicles, with notes on its use; a dynamometer with a hydraulic registering device, a recording torsion dynamometer by Morin, and a simplified form by Wüst.

New farm machinery, E. WROBEL (*Fühling's Landw. Ztg., 54 (1905), No. 18, pp. 625–628, figs. 4*).—A description of a new driving gear to reduce friction in fanning mills, improved interchangeable screens for threshing machines, and an improved universal seed drill.

New farm machinery, A. NACHTWEH (*Fühling's Landw. Ztg., 54 (1905), No. 19, pp. 667–671, figs. 4*).—A new universal farm mill adapted to both crushing and rough grinding. The rolls are smooth for half their length, being geared for both equal and unequal rates of speed.

New farm machinery, K. VORMFELDE (*Fühling's Landw. Ztg., 54 (1905), No. 20, pp. 695–701, figs. 4*).—A carbureter for making Benoid gas and a special gas engine for using this gas are described.

New farm machinery; the Heller plow for subsoiling, B. TÖLKSDORF (*Fühling's Landw. Ztg., 54 (1905), No. 16, pp. 555–557, fig. 1*).—Thorough subsoiling without heavy draft is claimed in this plow, which is constructed with a wedge-shaped subsoiler attached to an ordinary moldboard in such a way that the under layer of soil is moved laterally the width of one furrow without being turned over, the upper soil being turned over on top of the moved strip of subsoil.

RURAL ECONOMICS.

The state and agriculture in Hungary, I. DARÁNYI, trans. by A. GYÖRGY (*London: Macmillan & Co., Ltd., 1905, pp. XXII+264, map 1*).—This book is a discussion of the principles followed and the methods used by the Department of Agriculture of Hungary in the promotion of the agricultural interests of that country.

The questions of land tenure and fiscal policy are left on the side, and attention is centered upon the problems involved in improving the quality of cereals, hops, hemp and flax, wine, fruits, live stock, etc. "The intention in generally encouraging the agricultural industry was directed by the desire that our farmers, in the first place the small farmers, should be convinced of the advantages of 'qualitative production,' of using better seeds, producing more commercial plants, and, in general, of farming on a more scientific plan."

Cooperation among the farmers is encouraged by the government. "Acknowledging the great influence which farmers' clubs exercise on the development of

agriculture, the department uses every opportunity to stimulate their interest and activity. In preparing agricultural regulations and bills it consults these clubs, and also helps materially their shows, lectures, or any other of their public enterprises." And again, "the literature of cooperation has for a long time been subsidized by government."

"The Department of Agriculture has issued, for many years, reports on the condition of both home and foreign crops, for the use of the farmers, and these have continually increased in scope. . . . The number of correspondents was in 1895 only 875, but in 1902 already 1,143. There are, besides these, 87 correspondents dealing with insect pests." . . .

The measures taken to promote hemp growing illustrate the methods of promoting plant industries. "Hop growing, which is unable to supply more than half the home demand, is one of the industries in process of development. There is a regular and special instructor for hop growing, since special knowledge is required. To stimulate and equalize hop growing, the department distributes yearly tested hop seedlings among the producers."

The business side of farming, F. W. CARD (*Ann. Rpt. Bd. Agr. R. I., 19 (1903), pp. 66-81*).—This is mainly a discussion of the necessity of strict accounting on the part of the farmer, and of methods of keeping such accounts. It contains also a general discussion of the relation of fixed and movable capital on the farms.

At present in New England about one-half of the capital belonging to farmers is invested in land. It is pointed out that it is to the advantage of the farmer to decrease the proportion of his capital which is in land, in order to decrease fixed charges. These charges may also be decreased by arranging the farm work in such a way that both men and teams may be continuously employed.

The economics of good roads, W. E. MCCLINTOCK (*Ann. Rpt. Bd. Agr. R. I., 20 (1904), pp. 86-94*).—This paper reviews the conditions which have in earlier times and in other countries made the construction of good country roads necessary, and forms an estimate of the advantages to be derived at the present time by the construction of good roads.

The first argument is that products can be placed upon the market more cheaply. The second argument is that good roads would facilitate the consolidation of the country schools and thus improve the quality of rural education. It is argued also that good roads would tend to keep the young people in the country who at present have such a strong tendency to seek their fortunes in the cities.

The sugar production of the world, H. PAASCHE (*Die Zuckerproduktion der Welt. Leipsic: B. G. Teubner, 1905, pp. VI+338*).—This volume contains a statistical and descriptive discussion of the sugar production of the world.

The book is divided into three main divisions. The first part is devoted to the beet-sugar industry of the principal sugar-beet producing countries, the second part to the cane-sugar industry of the various countries where this industry is carried on, and the third to the competition of beet and cane sugar on the world market.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 7 (1905), Nos. 7, pp. 55-62; 8, pp. 63-70; Sup., pp. 71-78*).—Number 7 contains descriptive and statistical materials concerning yield and quality of crops in the United States, cotton seed and cotton-seed products in the United Kingdom, the United States exports and imports of rice and the exports of grain, the hop movement in the United States, and prices of agricultural products.

In No. 8, crop areas in Argentina, live stock in Germany, the area and production of tobacco in various countries, and flax seed and its products in the United Kingdom are the principal subjects discussed. The supplement to No. 8 contains the annual report of the Bureau and tables showing the acreage, production, and value of the principal farm crops of the United States in 1905.

Statistical yearbook of Austria, 1904 (*Statis. Jahrb. K. K. Ackerb. Min., 1904, pp. 305, pls. 10, dgms. 5*).—This reports contains statistics on grain, potato, sugar-beet, and wine production. The colored maps show the localities in which each of these products is grown.

The annual statistical report of the Tokyo Chamber of Commerce, 1905 (*Ann. Statis. Rpt. Tokyo Chamber Com., 1905, pp. VI+171*).—This report contains statistics of the receipts and shipments of agricultural products in the city of Tokyo, and the range of the price of these commodities.

Annual report of the bureau of industries for the Province of Ontario, 1904 (*Ann. Rpt. Bur. Indus. Ontario, 1904, pp. 48*).—Part 1 of this report contains statistics of the grain crops, root crops, hay and clover, fruit and fruit trees, live stock and dairy interests, labor and wages, market prices, and the values of farm property. Part 2 shows the total number and amount of chattel mortgages on record in Ontario on December 31, 1904, against (1) all occupants; (2) farmers; together with totals for the province for the past ten years.

State of Washington, its resources, natural, industrial, and commercial, 1905 (*Bien. Rpt. Bur. Statis. Wash., 1905, pp. 208+48, pls. 97, dgm. 1*).—This report describes the agricultural resources of the State of Washington. Statistics are given of the live-stock industry, of cereal, hop, and fruit production, and of the lumber industry of the State.

AGRICULTURAL EDUCATION.

Agricultural education in Belgium (*Notice sur l'economie rurale et l'enseignement agricole de la Belgique. Brussels: Min. Agr., 1905, pp. 93–190, figs. 25*).—This is a description of the system of agricultural education in Belgium, prepared for distribution at the Universal Exposition in Liège in 1905.

This description includes the following classes of institutions: (1) Colleges—the State School of Veterinary Medicine at Brussels, the Agricultural Institute at Gembloux, and the Agronomic Institute of the University of Louvain.

(2) Secondary schools, of which there are 3 separate agricultural schools located at Carlsbourg, La Louvière, and Huy, and 16 agricultural schools conducted as departments of other educational institutions; courses of agronomy in royal atheneums; State schools of horticulture at Ghent and Vilvorde and private subsidized schools of horticulture at Mons, Tournai, Liège, and Carlsbourg, and a school of practical horseshoeing at Molenbeek-Saint-Jean.

(3) Agricultural schools for women, including one higher agricultural school in connection with the Institute of the Sacred Heart and Immaculate Conception at Héverlé, and 10 secondary schools located, respectively, at Bastogne, Bouchout, Brugelette, Herve, Gooreind, Gyseghem, Oosterloo, Overyssche, 'S Gravenwezel, and Virton, besides 3 schools having departments for women located, respectively, at Cortemarck, Heule, and Waremme. There are also traveling dairy schools for women and in connection with the schools at Héverlé and Overyssche, schools of cheese making.

(4) Popular instruction, including primary agricultural and horticultural trade schools (10 of which are agricultural and 9 horticultural departments of other schools), and popular instruction for adults (itinerant instruction consisting of from 15 to 30 lectures on agriculture, horseshoeing, apiculture, and other special subjects).

In addition the statistics of agricultural education are presented; the service of agronomes (graduates of agricultural colleges engaged in extension work for the State), and accounts of institutions connected with agricultural educational institutions, such as botanic gardens, chemical and bacteriological institutes, analytical laboratories, experiment stations, and reading circles.

The place of the agricultural and mechanical college in the educational scheme of the South, B. Ayres (*South. Ed. Rev., 2 (1906), No. 8, pp. 485–493*).—The development and present status of agricultural and mechanical colleges are discussed, and a plea is made for a closer union between southern institutions of this class and other colleges and preparatory schools of the South.

It is pointed out that the college entrance requirements recommended by the Association of Colleges and Preparatory Schools of the Southern States do not take the agricultural and mechanical colleges into consideration. The writer calls attention to the rapid growth in enrollment and beneficent influence of the great universities of the West, and endeavors to show how closer cooperation between all the educational institutions of the South would lead to similar progress.

Nature study and agriculture (*Course of study and syllabus for elementary schools. Albany: N. Y. State Ed. Dept., 1905, pp. 154–172*).—This syllabus presents material and suggestions for nature study extending over the first 6 years of the elementary school curriculum, and agriculture extending over the remaining 2 years.

Both nature study and agriculture are outlined by years, the former including studies of animals, plants, and natural phenomena (weather, water, winds, clouds, etc.). The first year of elementary agriculture is devoted to studies of domestic animals and plants of the farm, and the second year takes up the study of the State of New York considered as a great farm, with special studies on dairying; pastures, meadows, and forage; alfalfa as fodder; fruit growing, and insect pests and methods of destroying them. A list of reference books for the use of teachers is appended.

"The aim in the first five years is to put the child into sympathetic touch with his environment, and to give him certain units of basal knowledge with which he may interpret the facts of geography and agriculture, which later are to be based upon this nature study. . . . In the fourth and fifth years nature study, observational geography, and agriculture, beginning in the locality and widening out into the State, are closely related, and they supplement each other." In the sixth year there is a review, and some generalizations are made in preparation for the study of agriculture, which begins in the seventh year.

There is a logical sequence in the work as outlined. This is not strikingly apparent in the work of the earlier years, but gradually the pupil is led to make a special study of the life of certain plants and animals, the distribution of these plants and animals, and the relation of plants to soil, plants to animals, and of both plants and animals to man. The pupils are led to see that they are studying agriculture "for the purpose of finding out how to enhance the animal and plant values to man," and that "these values depend not only upon improved soil conditions and economic treatment of farm products, but also upon intelligent marketing and upon the principles of economic exchange of home products for those raised in other sections of the State and country."

Syllabus for secondary schools. Physical geography and agriculture (*N. Y. State Ed. Dept., Secondary Ed. Bul. 27, pp. 132–157*).—The syllabus for physical geography includes outlines for a study of the earth as a planet, the air, the ocean, water other than the ocean, and the land. It is recommended that as much time be devoted to the study of the land as is devoted to the four other subjects outlined.

The syllabus on agriculture was prepared at the request of the Education Department by representatives of the faculty of the College of Agriculture, Cornell University. The outline presents an orderly arrangement of work for three periods a week extending over one year, and it is recommended that this work be taken in the second year of the high school after the pupil has completed one year's work in biology and has acquired some knowledge of elementary chemistry. It is also recommended that abundant laboratory work should be provided, at least one period out of every three being devoted to such work.

The order of treatment and the reason for adopting this order are thus stated in the syllabus: "Agricultural operations are conducted for two immediate purposes—to raise plants and to raise animals. Plants are raised either for their own value or for their use in the feeding of animals. In studying agriculture, therefore, it is well to begin with the plant, then proceed to the animal, and then consider questions of practice and management that grow out of these subjects."

The studies on the plant and crops include the plant itself, environment of the plant, and actual study of the leading crops of the community. Under animals and animal husbandry are included studies of domestic animals and their relationships, the nutrition of animals, and animal products. Part 3 of the syllabus is devoted to farm schemes and management, including kinds of farming, rotations, lay-out of farms, tillage, drainage, and irrigation.

Agriculture in the public schools, F. MUTCHLER (*Ann. Rpt. Conn. Bd. Agr., 38 (1904), pp. 215–227*).—An address given at the annual midwinter meeting of the Connecticut Board of Agriculture, Hartford, December 14–16, 1904, for the purpose of showing how elementary agriculture should be taught.

School gardens, B. T. GALLOWAY (*U. S. Dept. Agr., Office Expt. Stas. Bul. 160, pp. 47, pls. 5*).—A report is given on the school garden work in the District of Columbia, conducted in a cooperative way by this Department and the normal schools of the District, under the direction of the Bureau of Plant Industry and Miss Susan B. Sipe, instructor in botany in Normal School No. 1.

The garden work described includes the boys' vegetable gardens on the grounds of this Department, the home gardens of the normal school pupils, and the improvement of school grounds at Normal School No. 1 and 32 other schools in the District. Supplementary to this report is a report by Miss Sipe on school gardens visited by her in the summer of 1904 in Hartford, Conn.; Boston, Brookline, Hyannis, and Worcester, Mass.; St. Louis, Mo.; New York City, Yonkers, and Rochester, N. Y.; Cleveland, Ohio, and Philadelphia, Pa. Throughout the bulletin an effort has been made to bring out the educational trend of garden work in the different enterprises described.

Municipal school gardens conducted by the Board of Public Education, Philadelphia, HELEN C. BENNETT (*Philadelphia: Bd. Pub. Ed., 1905, pp. 31, figs. 19*).—This is a report by the Supervisor of School Gardens in Philadelphia on the school garden work conducted in 1905 under the auspices of the Board of Public Education. The report includes outlines of lessons given to those working in the gardens, a description of nature-study material sent to schools, and brief accounts of school gardens in Boston, Hartford, New York, and Yonkers.

The ideal forestry college (*Indian Forester, 31 (1905), No. 2, pp. 61–73, pls. 3*).—The author visited the forestry colleges and institutes existing in Europe and gives his impressions as to what an ideal forestry college or school should be. The subject is considered under the various headings of situation, buildings, staff, studies, arrangement of the main educational buildings, college gardens, and college educational forests.

Forest school, H. S. GRAVES (*Bul. Yale Univ., 1. ser , 1905, No. 4, pp. 182–186*).—An account of the work of the Yale School of Forestry during the year.

A summer term in forestry has been added to the junior year. This course begins in July of each year instead of the following September. During the preceding summer it was devoted entirely to the subject of sylviculture and forest mensuration at Milford, Pa. By this plan much more time is available for field work than heretofore. During the year 84 students received instruction in forestry.

Soil and drainage, A. B. GRAHAM (*Agr. Col. Ext. Bul. [Ohio State Univ.], 1 (1905), No. 2, pp. 6–9, figs. 3*).—Ten simple experiments for use in public schools are described.

The educational beehive, E. F. BIGELOW (*Nature-Study Rev., 1 (1905), No. 5, pp. 202-209, figs. 4*).—A description is given of an observation hive invented by the author for use in nature-study work in schools.

Suggestions for grain-growing contests, score cards, and rules for judging wheat, oats, and corn, C. P. BULL (*Univ. Minn., Dept. Agr., Rural School Agr. Bul. 2, pp. 63, figs. 19*).—This bulletin is prepared for the purpose of encouraging grain-judging contests among the pupils in the common schools in each county of the State.

A general study of seeds and seed testing, including weights per bushel of some common seeds, market grades of wheat and oats, germination, and rules for judging seed, is followed by more particular and detailed studies of wheat, oats, and corn, in which the history, types, culture, harvesting, marketing, and judging of each class of grain are treated. Specimen score cards are given and rules for the use of the score cards. Following these studies there is a chapter on crop rotation and field management and a chapter giving suggestions for practical exercises in connection with the other work.

Legislation relating to farmers' institutes in the United States, J. HAMILTON (*U. S. Dept. Agr., Office Expt. Stas. Bul. 135, rev. ed., pp. 35*).—In the revision of Bulletin 135 of the Office (E. S. R., 15, p. 523) the institute legislation of the Province of Ontario, Canada, is omitted. New enactments and amendments to farmers' institute laws, as well as changes in appropriations made since 1903, are included. New legislation has been enacted in Georgia, Oregon, South Dakota, and Wyoming, and amendments made in New York and Virginia.

Organization lists of the agricultural colleges and experiment stations in the United States (*U. S. Dept. Agr., Office Expt. Stas. Bul. 161, pp. 95*).

MISCELLANEOUS.

Eighteenth Annual Report of Illinois Station, 1905 (*Illinois Sta. Rpt. 1905, pp. 13*).—This contains a statement of the principal lines of work, a list of station bulletins, and a detailed financial statement for the fiscal year ended June 30, 1905.

Twenty-fourth Annual Report of Ohio Station, 1905 (*Ohio Sta. Bul. 163, pp. XXV*).—This includes an announcement concerning the work of the station, the organization list, a report of the board of control, a financial statement for the fiscal year ended June 30, 1905, and a report of the director summarizing the work of the station during the year.

Twenty-first Annual Report of the Bureau of Animal Industry, 1904 (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1904, pp. 632*).—This includes a report of the chief of the Bureau on the work done during the year, brief biographical sketches of the late E. A. de Schweinitz and H. E. Alvord, numerous articles previously noted or abstracted elsewhere in this issue, miscellaneous information, and the rules and regulations of the Bureau issued in 1904.

The articles previously abstracted from other sources are as follows: Foot-rot of sheep (E. S. R., 16, p. 713); the etiology of hog cholera (E. S. R., 17, p. 87); experiments concerning tuberculosis (E. S. R., 15, p. 916; 16, p. 1022); information concerning the milch goats (E. S. R., 17, p. 77).

The miscellaneous information, based mainly upon consular reports, consists of brief articles on the following subjects: The horse of Abyssinia; government aid to horse breeding in Italy; German imports of horses; the cattle industry of Brazil; the live-stock industry in Japan; live stock in Mexico; Venezuelan cattle for Cuba; number of cattle in Australasia; number of sheep and cattle in Buenos Ayres; importation of cattle into the Transvaal; American cattle and mules in northern Brazil; Russian association for breeding hogs and cattle; the frozen-meat trade with Great Britain; American meat a necessity in Germany; Germany's attempt to produce

canned meat; American meats in France; Spain's imports and exports of animal products; Prussia to make sausage; Argentine meat in Belgium; exports of Argentine animals and animal products; exports of animals and animal products from Denmark, 1903; imports and exports of animals and animal products of Uruguay; trade in animal products with Trinidad; frozen-meat trade of Argentina; German imports of animal products from Argentina; exports of frozen meats from New Zealand; New Zealand's exports of animal products; oleo oil in Turkey; number of sheep slaughtered in refrigerating plants in Argentina, 1897–1903; number of sheep in Australasia, 1885–1902; the sheep of Abyssinia; imports of wool at Boston, New York, and Philadelphia; the Australasian wool clip; wool exports from Australasia; production of wool in Argentina and Uruguay, 1893–1903; production and consumption of meat and dairy products in United Kingdom; decline of British butter making; cool-cured cheese in Canada; consumption of butter in Germany; glazed butter in Germany; dairy methods in Mexico; production and exportation of butter in Argentina; some dairy statistics of Queensland; milk-powder factory in France; galalith from skim milk; butter, cheese, poultry, and eggs in Kansas; consumption of poultry and eggs in Great Britain; testing for age of eggs; the Sicilian, or Buttercup, breed of chickens; Utility Poultry Club's laying competition; Australian egg-laying competition; goat raising in Mexico; the goats of Abyssinia; reindeer hair and its uses; frozen-rabbit industry of Australia; rabbits *v.* sheep in Australia; transportation in Persia; horses, cattle, and meat in France; poultry and eggs in the United Kingdom; and municipal slaughterhouse of Berlin.

Experiment Station Work, XXXI (*U. S. Dept. Agr., Farmers' Bul. 233, pp. 32, figs. 5*).—This number contains articles on the following subjects: Root systems of plants; fertilizers for asparagus; mushroom culture; onions in the Southwest; ether forcing of rhubarb; noodles; condimental feeds; beef *v.* dairy type for beef production; feeding skim-milk calves; animal food for ducks; milk from diseased cows; and cider vinegar.

Experiment Station Work, XXXII (*U. S. Dept. Agr., Farmers' Bul. 237, pp. 32, figs. 6*).—This number contains articles on the following subjects: Lime and clover; plant-food requirements of fruit trees; apple growing in New York; running out of seed wheat; high-protein seed wheat; tobacco seed selection; cover crop for tobacco fields; cereal breakfast foods; damaged wheat as feed; bedding for cows; amateur poultry raising; care of cream on the farm; paying the patrons of creameries; gassy fermentation of Swiss cheese; and yeast as a disinfectant.

Press bulletins (*Ohio Sta. Bul. 163, pp. 273–281*).—Reprints of press bulletins on the following subjects: Preliminary report of twelve years' experiments with wheat; lime as a fertilizer; Hessian fly and wheat midge; suggestions concerning the use of fertilizers; and a warning against fraud in the sale of nursery stock.

Index of Massachusetts State Station publications, vols. 1-12, 1883-1894 (*Massachusetts Sta. Index Number, 1905, pp. 44*).

Agriculture in Denmark (*Verslag. en Meded. Afdeel. Landb. Dept. Landb., Nijv. en Handel, 1905, No. 5, pp. 86*).—This is a general treatise on agricultural conditions in Denmark, including discussions on farm values and management, stock raising, exports, particularly of eggs, agricultural societies, and live-stock expositions.

NOTES.

Connecticut College.—Edwin Gilbert, of Georgetown, Conn., who died at Crescent City, Fla., February 28, bequeathed to the college a farm of about 356 acres, together with all tools, machinery, agricultural implements, live stock, and buildings, upon condition "that the same be taken and maintained in connection with said college as a farm and for the purpose of teaching or instruction in farming practically." In addition $60,000 was left to the college, the interest of which is to be used for caring for the farm and for instruction in agriculture, especially animal husbandry. The farm is said to be worth from $35,000 to $40,000.

The new brick and stone dormitory, for which the last legislature appropriated $60,000, is rapidly nearing completion, and the building will be ready for occupancy in time for the summer school. This dormitory contains 66 single bedrooms and 30 studies, which, except in the case of a few single rooms, are grouped in suites of 3, 2 bedrooms being connected with each study.

Delaware College.—J. A. Foord has resigned his position as professor of agriculture, to take effect early in April, and will become assistant professor of agronomy at the Ohio State University, instead of "assistant in agronomy," as previously announced.

Hawaii Station.—Jared G. Smith, director of the station, has returned to Washington for a few weeks. The sum of $1,750 has been raised by private subscription and placed at the disposal of the station for carrying on experiments in rice culture, with a view to decreasing the cost of production by modern methods and developing varieties better suited to local conditions or the substitution of other commercial crops on rice lands. The average annual rentals for rice land in Hawaii are about $35 per acre, which fact limits the prospects of crop substitution. Six thousand dollars has also been promised by private contributors to carry on a field experiment with tobacco, to test this crop on a commercial scale. The experiment will be made at Hamakua, where experiments in tobacco growing have been made by the station in previous years. An experiment in raising grapes for wine making has also been started on the island of Maui in cooperation with local farmers. A vineyard of 124 varieties of wine grapes has been set out.

Kansas College.—W. E. Mathewson, assistant professor of chemistry in the college, has been appointed assistant chemist of the station.

Kentucky Station.—W. E. Scherffius, chemist of the station, has been appointed agriculturist to fill the vacancy caused by the removal of J. N. Harper to the South Carolina Station.

Louisiana Stations.—The office of the Crop Pest Commission has been removed from Shreveport to Baton Rouge, and will now have its office in the experiment station building on the university campus at Baton Rouge. Arrangements have been made for cooperative experiments with this Department in studies on rice, including varieties, fertilizer tests, etc.

Maryland Station.—Walter R. Ballard, B. S., Kansas Agricultural College, has been appointed assistant horticulturist to succeed S. B. Shaw, resigned. O. C. Gibbs has been appointed clerk, vice H. H. Howell, resigned.

Minnesota University and Station.—According to the *Farm Students' Review*, the farmers' short course this year numbered 86, the largest attendance of any year thus far. The station is now ready to distribute a new variety of wheat, to be known as Minnesota No. 188. This variety has been in the test plats at the university farm for 10 years and has proved to have superior yielding qualities. It will be sold in small quantities, as is the usual custom.

Nebraska Station.—Press reports state that several new buildings have been erected at the substation at North Platte. These improvements include a $3,200 dwelling for the superintendent of the station and a $2,500 barn. Cattle barns, a small hog house, and a granary are now under construction.

New Hampshire College.—Arrangements have been concluded for a new library to cost $30,000, of which $20,000 was given by Andrew Carnegie and the remaining $10,000 by the Hamilton Smith estate of Durham. The Durham Library Association will turn over to the college library its collection of books, valued at $10,000, and also the income from its invested funds of $11,000 for the purchase of books. In exchange for this the college will extend the privileges of the consolidated library to all citizens of the town. The town of Durham will make a small appropriation annually toward the upkeep of the library.

Mrs. Hamilton Smith, of Durham, has recently given the sum of $10,000 for a new women's hall, which is much needed. The new $25,000 drill hall and gymnasium was dedicated the latter part of January. The building contains a main hall, 58 by 98 ft., with lockers and shower baths in the basement. The main floor is unobstructed, the roof being supported by steel trusses, which also support the balcony and running track. The building also contains a college club room, 20 by 40 ft., and offices and a class room for the military department and the physical director.

Rutgers College.—Dr. W. H. D. Demarest has been elected president of the college to succeed Dr. Austin Scott, who, as previously noted, has retired on account of ill health. Dr. Demarest has been acting president for several months past.

Cornell University.—According to *The Cornell Countryman* there were 237 students in the winter course which, with the 223 in the regular and special courses, and 30 graduate students in agriculture, gives a total of 490, the greatest total enrollment the college of agriculture has ever had. The registration in the winter course in poultry increased from 17 last year to 35 this year.

Ohio State University.—W. H. Freund has been added to the teaching staff of the dairy department in the university, as noted in *The Agricultural Student*. He has studied at Wisconsin, Guelph, and Kingston (Ontario), and will teach cheese and butter making in his new position.

Pennsylvania Station.—With a view to helping the farmers of the State to secure some information upon the important matter of the fertilizer requirements of their soils, a simple form of field test with fertilizers has been devised, involving the use of only 5 plats and less than $2 worth of fertilizer. Over one hundred such experiments have already been arranged for in cooperation with the station in different parts of the State, the station furnishing the fertilizer weighed out and ready for application. The station is also in correspondence with a considerable additional number of farmers, who desire to undertake the work entirely at their own expense. The station, in all cases, will furnish full directions for the experiment and suitable blanks for recording the results. It is hoped that many farmers will avail themselves of this opportunity, and that by means of these experiments it may be possible to secure indications as to the fertilizer requirements of different types of soil in Pennsylvania.

Rhode Island Station.—The term of Melville Bull, of Newport, who has been a member of the board since the station was established, expired January 31, 1906, and Robert S. Burlingame, of Newport, was appointed his successor. The new organization of the board is as follows: Charles Dean Kimball, president; Robert S.

Burlingame, vice-president; C. H. Coggeshall, clerk and treasurer; Thomas G. Mathewson and Jesse V. B. Watson.

The station is planning this season, in cooperation with the Bureau of Soils of this Department, to continue the investigations concerning the influence of sodium salts upon plant growth, and in addition to conduct a considerable number of cooperative field experiments in different parts of the State for the purpose of making a special study of the ability of certain plants to reveal specific soil requirements.

Vermont University and Station.—Arrangements have been made for the purchase of a valuable tract of ground adjoining the college campus, upon which Morrill Hall, the new agricultural building, will be located.

Virginia College and Station.—The State legislature has appropriated $86,000 for the college of agriculture and the experiment station for the biennial period. Of this amount $60,000 is to complete and equip the agricultural building, $5,000 a year for the experiment station, $6,000 a year for the crop pest commission, and $2,000 a year for furthering the cattle tick work.

M. P. Jarnagin, a former student of the University of Tennessee and a graduate of the Iowa Agricultural College, has been appointed assistant in animal husbandry in the college and station.

Wisconsin University and Station.—The registration in the college of agriculture this year numbers 1,052, and includes representatives from 12 States and 6 foreign countries. Of these 6 are graduate students, 136 in the long course, 322 in the 14 weeks' short course, 178 in the dairy course, and 410 in the farmers' course. Plans are well under way for the erection during the present summer of a building for agricultural engineering and an agronomy building.

The station has established 3 substations or farms in the northern part of the State, immediately south of Lake Superior. Over much of this district the forests have yielded up their pine lumber, and agriculture is almost undeveloped. In this region is a belt of heavy clay soil of very fair fertility, varying in width from a few miles to 15 or more, and comprising about a million acres. Immediately south of it is a sand region of very low to fair fertility. About 20 acres of land have been rented from the county poor farm several miles south of Superior City, in the red-clay region. This has been tile drained and will be planted with various crops the coming season. Near Ashland 30 acres of stiff red clay have been leased for a similar demonstration farm, and the third will be located in the vicinity of Iron River on sandy soil. It is expected that the expense of these farms will amount to about $6,500 annually, which will be paid wholly from State funds. It is planned to appoint a superintendent to have charge of the work, who will reside at Iron River and look after the other two farms. The work at the latter will be carried on by persons living on the farms or near by.

Wyoming University.—The Wyoming supreme court has handed down a decision in the Lander Agricultural College case, unfavorable to the latter. Under an enabling act passed in 1892 the people of the State voted to locate the agricultural college at Lander in Fremont County, but the legislature failed to establish the institution and designated the University of Wyoming as the proper institution to receive the Morrill and Hatch funds. A year ago the State legislature repealed the action locating the college at Lander, although the board of agriculture had received and partially used an estate of some $40,000, left by Philip Weiser, in starting an agricultural college at Lander. The Lander people raised money by private subscription to try the case in the courts, and served an injunction on the State treasurer to prevent his turning over the Morrill fund to the board of trustees of the university. The supreme court decided that the legislature had a constitutional right to repeal its former action and that the State agricultural college could not be moved from Laramie to Lander without legislative action, which leaves the university in possession of the Federal funds for its agricultural college and experiment station. The Lander people have now taken an appeal to the United States Supreme Court.

Measures before Congress.—A delegation of New England experts in the extermination of the gypsy and brown-tail moths were given a hearing before the House Committee on Agriculture February 13, upon the measure providing for control of these insects. As a result of the hearing, it was decided to draft a new bill, confining the work to the gypsy moth and providing for the establishment of a quarantine against its spread. This bill, since introduced, carries an appropriation of $250,000 as before, and places the work in the hands of the Secretary of Agriculture, in cooperation with the authorities of the States concerned and the State experiment stations.

A conference of representatives of the Southern States was also held in Washington to consider a bill appropriating $500,000 to aid in the extermination of the Texas fever cattle tick.

The Adams bill, increasing the endowment for the agricultural experiment stations, passed the House February 15, and the Senate March 12. There were no amendments in either case, and practically no objection. In its report upon the bill the House committee expressed its appreciation of the stations in the following terse language:

"The State experiment stations have done a remarkable work in developing the agricultural interests of the United States. No other single agency has contributed so much to the agricultural education of this country, or has eliminated more errors from farm practices, or has added more to the profits and comfort of farm life."

Other bills of interest to agriculture have been introduced as follows: Authorizing the Secretary of Agriculture to investigate systems of farm management and types of farming prevailing in different sections of the United States, the means used for maintaining soil fertility, methods employed in the production, utilization, and marketing of crops, and demonstration of improved methods of farming, $120,000; providing an appropriation of $100,000 for experimentation looking to the development of crops that can be best raised on semiarid lands by dry farming; authorizing the Secretary of Agriculture to make investigations to determine the best methods of utilizing small water supplies in irrigation, $50,000; to establish a Weather Bureau observatory at Sheridan, Wyo., $5,000; appropriating $5,000 to be expended by the Minnesota Station for investigating infectious diseases of domestic animals in Minnesota, their prevention, treatment, etc.; a concurrent resolution calling for the printing of 15,000 sets of the Farmers' Bulletins of this Department, from No. 1 to the last number issued, nearly two-thirds of which are for distribution to school libraries; to extend the provisions of the National Irrigation Act to the State of Texas; to apply a portion of the proceeds from the sale of public lands to the State normal schools for instruction in agriculture, the initial appropriation being $500,000, with an increase of $100,000 annually for 5 years, making the final annual appropriation $1,000,000; providing for the purchase of a site and the erection of a suitable building in the District of Columbia for the use of the Forest Service as a laboratory for experiments in the seasoning and preservative treatment of construction and other timbers, for testing the strength of timbers, and for determining means of preventing waste in lumbering and in the manufacture of wood products, $100,000; granting to the State of North Dakota 30,000 acres of land to aid in the maintenance of a school of forestry, the school having been established by the State legislature and located at Bottineau; appropriating the receipts from the sale of public lands in the State of Minnesota to the construction of drainage works for the reclamation of swamp and overflowed lands; authorizing the Secretary of Agriculture to make surveys and investigations to determine the benefits to be derived from the drainage of the public swamp lands of the several States and Territories, to prepare estimates of the cost of the same, and appropriating $10,000 for the work the first fiscal year, provision thereafter to be made in the annual appropriation acts for the Department of Agriculture; to enable the Department of Agriculture to conduct demonstration experiments in the eradication of pear blight in Idaho, in cooperation

with the Idaho Station, $10,000; and authorizing the registration in the United States Patent Office of the names of new varieties of horticultural plants, by the person who discovers, originates, or introduces the variety, under the law authorizing the registration of trade-marks.

Agricultural Education at the Meeting of the Department of Superintendence.—The Department of Superintendence of the National Educational Association held its annual meeting in Louisville, Ky., February 27 to March 1, there being about a thousand in attendance. This Department was represented by Mr. John Hamilton of this Office.

The subjects on the programme were chiefly such as related to city and town conditions. The afternoon of the last day, however, was devoted to the consideration of industrial training in the public schools. O. J. Kern, superintendent of schools of Winnebago County, Ill., presented a paper upon The Form of Industrial Training Most Practical and Best Suited to the Country Child. He made the point that education is primarily for self-support, and quoted President Roosevelt's declaration that every man in a country like ours should be "able to carry his own weight." He maintained that education should be of direct service as a wage-earner; that to effect this an effort should be made to interest country children in the things that they will be expected to understand when they come to engage in rural occupations. For this purpose the school garden, the experiment plat, and field excursions are valuable aids.

Charles H. Keyes, superintendent of schools of South District, Hartford, Conn., followed with a paper upon The Form of Industrial Training Most Practical and Best Suited to the City Child. In this he called attention to the danger there is in having the city child misunderstand the country, and declared it as his conviction that the city boy should know how it feels to actually do the things that the farmers' occupation requires. That this may be possible, school gardens for city children are a necessity.

A round-table discussion on agricultural education was held in the afternoon and evening of Monday, February 26, led by Supt. E. E. Balcomb, of the State Normal School, Weatherford, Okla. The discussion took the general direction of methods for introducing agricultural studies into the rural schools. There was general agreement as to the necessity for introducing agricultural study in some form into the public schools, and that this may be efficiently done opportunity must be afforded teachers to receive instruction in agriculture in the normal schools.

The Committee of the Round-Table appointed to draft resolutions summed up the points agreed upon in the following declarations, which were afterwards adopted by the Department of Superintendence:

"*Resolved*, That the Department of Superintendence of the National Educational Association is in hearty accord with that part of the report of the Honorable James Wilson, Secretary of Agriculture of the United States, in which he encourages the teaching of elementary agriculture in the public schools, and respectfully requests Congress to grant the appropriation of $13,620 which he has asked for to enable him to investigate and report upon the progress and present condition of agricultural instruction and institutions in this and foreign countries.

"*Resolved*, Second. That since it is essential to the successful teaching of industrial subjects in the public schools that the teachers shall first be trained for this work, we urge the State normal schools to give special attention to instruction in elementary agriculture, manual training, and domestic science.

"*Resolved*, Third. That in order to meet the extraordinary expenses of properly equipping these schools for giving this instruction we urge the adoption of the Burkett-Pollard Bill now before Congress making appropriation to the States for this purpose."

Traveling Summer School of Agriculture.—*The Cornell Countryman* announces that arrangements are being made for a traveling school during the summer, to be in

charge of one of the professors of the college. The plan has grown out of the desire of many of the men to travel in this country for the purpose of studying agricultural conditions, special agricultural industries, and the management of large farm enterprises. A petition signed by 17 students led to deciding upon the plan for such a traveling school to be undertaken the coming summer, and this plan has been ratified by the board of trustees.

"Certain academic requirements are made obligatory, as well as the consent of the faculty concerning each individual participant. The trip will last at least six weeks, and a deposit of $400 must be placed with the university treasurer, unexpended moneys to be returned. Six hours of university credit are given. It is hoped that Prof. Thomas F. Hunt will take charge of the first trip—summer of 1906."

The party hopes to have its own cars, a sleeper and a dining car, the latter being equipped with books and writing materials and serving as a study room in the evening. The proposed route lies through Washington, the cotton, tobacco, and trucking States of the South, the sugar and rice industries of Louisiana, the cattle ranches of Texas, and to the far West where irrigation methods, etc., will be studied. This is a new departure in agricultural education and will be followed with much interest.

Colorado School of Forestry.—We learn through *Science* that Gen. W. J. Palmer and Dr. W. A. Bell, of Colorado Springs, have given to Colorado College a tract of 15,000 acres of forest land to serve for field work in the practical study of sylviculture and forest botany. The lecture course in the forestry department will be given at Colorado College. The tract is situated at the foot of Pikes Peak, and affords a splendid opportunity for the study of irrigation, as well as forestry problems. It is stated that when Colorado was first settled it contained 36,000 square miles of forest area, and since that time 30,000 square miles of virgin forests have been destroyed. The forest school will be opened next September.

A People's High School in Austria.—A people's high school, similar to the people's high schools in Denmark (E. S. R., 17, p. 519), is maintained at Otterbach, near Schärding, by George Wieninger, president of the local agricultural society, who meets all expenses of the institution except the salaries of nonresident lecturers, which are paid by the State. The equipment of the school includes a model farm, museum of agricultural, natural science, and ethnographic specimens, a large auditorium, and a library. Free lectures and demonstrations have been given since 1845, and since 1890 32 of these have been given each year. These lectures and demonstrations are given on Sunday and are attended annually by from 3,000 to 4,000 farmers and farmers' sons who can not attend school. The object of the lectures is to assist in the general instruction of the rural population and to diffuse special knowledge concerning modern agricultural methods. Those who attend 100 lectures receive a diploma; those who attend 200, a silver medal, and those who attend 300, a gold medal. Lectures are given on potatoes, fertilizers, forestry, science, and agriculture, diseases of digestive organs, the herd book in animal husbandry, sugar as food, etc. In addition to these Sunday lectures short courses of from 1 to 2 weeks are offered in feeding, distilling, bookkeeping, poultry culture, dairying, and in normal work for teachers.

Agricultural Education at Antigua.—As described in a recent number of the *Agricultural News*, instruction in agriculture in Antigua includes lessons at the grammar school in agricultural science and practical work in the school garden. It is claimed that pupils pursuing such a course are able upon leaving school to deal much more intelligently and successfully with agricultural problems than those who have no such training. Attention is also given at the grammar school to the training of teachers for giving some instruction in agricultural subjects in the elementary schools. With this object in view courses of lectures on the elements of plant physiology and on tropical hygiene have been given to the teachers of the elementary schools of the island and to the students of a female training college in Antigua.

The importance of school garden work is also emphasized. At the present time 72 boys are taking the work in agricultural science and 40 teachers are pursuing the training courses.

Training Oklahoma Teachers for Elementary Agriculture.—The Southwestern State Normal School of Oklahoma, at Weatherford, has recently established a department of agriculture and physiography, which is in charge of E. E. Balcomb. It has begun publishing a Teachers' Bulletin on Agriculture and School Improvement, which is sent free to teachers and others interested in such work. The December and January numbers of this bulletin contain suggestions for teaching agriculture, taking up in some detail such matters as seed testing, grafting, and budding, and giving directions for organizing local branches of the School and Home Improvement League.

Agriculture in Public High Schools.—The Sac City, Iowa, High School has introduced an agricultural course which has an enrollment of 56 pupils. The Higginsville, Mo., High School has a class of 38 boys and girls studying elementary agriculture.

Simmons College Domestic Science Department.—Simmons College, Boston, according to a note in the February *Everyday Housekeeping*, has recently taken over the property and management of the Boston Cooking School, and has established a regular four-year course in domestic science and a one-year course for those who do not wish to devote more time to this study. Cooking, sewing, marketing, elementary chemistry, bacteriology, nutrition, and other subjects will be included in the curriculum.

Philippine Bureau of Forestry.—The Philippine Reorganization Act, which has been approved by the governor-general, provides that the chief of the bureau of forestry shall hereafter be known as the director of forestry. The position of assistant chief and the division of forest inspection are abolished, the work of the forest inspection being transferred to the bureau of internal revenue. This transfer will permit of the foresters in the different districts devoting their entire time to the sylviculture study of the forests, the location of areas best suited for the commercial exploitation of timber and minor forest products, and the inspection of logging operations of various licensees. A recent order provides that for a period of 5 years the residents of the islands shall be allowed to utilize, free of charge and without license, forest products for personal use, trees of the first group excepted. Timber cut for sale will be paid for as heretofore.

At present there are 8 American trained foresters and assistant foresters in the islands, and others are expected early in 1906.

Scientific Commission to Study Rural Hydraulics.—A recent report of the Secretary of Agriculture to the President of France, reviewed in *Journal d'Agriculture Pratique*, recommends that the commission for scientific studies be increased from 16 to 24, in order to carry out the order of last March, directing the study of surface and underground waters. He recommends that the work should not be limited, as hitherto, to the problems of irrigation and drainage, but should include detailed studies of rainfall, runoff, and watersheds, in their relation to water power, and special attention should be given to underground supplies for towns. In the latter connection he says: "Without hoping to discover precise mathematical laws for such complex phenomena, we may still hope that after collecting a large mass of reliable data, they may be so grouped and coordinated as to furnish a fair guide to engineers engaged in developing underground waters."

A New Testing Station for Farm Machinery.—The machine-testing commission of Hanover, Germany, has decided to enlarge its sphere of activity to include a permanent testing station, which is to be in charge of Prof. Alwin Nachtweh. The new station will be located in the city of Hanover.

International Windmill Convention.—According to an item in *Journal d'Agriculture Pratique*, the Secretary of Agriculture of France has called together that part of the commission for scientific study which is employed in investigating wind power for irrigation and other pumping. M. Angot of the interior meteorological office has

been engaged in finding a new design for registering anemometers, and has had three made for precise work. M. Ringelmann, director of the station for testing machinery, has undertaken to arrange an international convention which the commission believes will have a very beneficial effect on manufacturers of windmills for raising water. The arrangements have met with the approval of the Secretary of Agriculture.

Agricultural Exposition in Paraguay.—The National Agricultural Society of Paraguay will hold an exposition at Asuncion, beginning May 15, 1906. The exposition will include exhibits of live plants, fruit, and cultivated plant products, rural industries, dairy industries, poultry and apiculture, and sericulture.

Miscellaneous.—It is learned from *Nature* that a number of men interested in agricultural problems recently gathered at Christiania, Norway, under the presidency of Prof. John Sebelien, to celebrate the acquisition of national independence. A fund was started for the purpose of fostering research in Norwegian agriculture, to which all Norwegians both at home and abroad have been invited to subscribe. When the sum reaches 15,000 crowns (about $4,000) it is proposed to offer prizes for essays on particular questions, and to reward Norwegian scientific work in certain branches of learning; and later it is the intention to give direct financial aid to research work in agricultural science.

The government of the Gold Coast has established experimental cotton farms at Anum and Labolabo, for the purpose of testing varieties of cotton and determining the best time of planting cotton for that region.

The Botanical and Agricultural Department of the Gold Coast provides annually an elementary course in theoretical and practical agriculture at the Aburi Garden to train teachers in agriculture for the public schools. The department also maintains apprenticeships to prepare young men for subordinate positions in the department or for overseers of farms and plantations.

The agricultural chemical experiment station at Spalato, Austria, has been provided with commodious and thoroughly modern quarters in the new building of the Royal Agricultural Institute for Teaching and Experimentation. An illustrated description of the new building is given in the January issue of *Zeitschrift für das Landwirtschaftliche Versuchswesen in Oesterreich.*

Prof. S. P. Langley, secretary of the Smithsonian Institution in this city, died February 27.

Dr. A. W. Harris, formerly director of this Office, and at present director of the Jacob Tome Institute at Port Deposit, Md., has been elected president of the Northwestern University. Dr. Harris will enter upon his new duties in the fall.

The death is announced of Dr. H Ritthausen, professor of agricultural chemistry in the University of Königsberg until his retirement in 1900, and widely known for his investigations upon the albuminoids.

Prof. A. Zimmermann, director of the biological agricultural institute at Amani, German East Africa, has been appointed director of the agronomic station at Salatiga, Java.

Dr. Friedrich Petersen, an official of the Prussian Ministry of Agriculture at Berlin, is traveling in this country for the purpose of studying the breeding of cattle and horses especially, and agricultural conditions in general.

O

EXPERIMENT STATION RECORD.

Vol. XVII. April, 1906. No. 8.

The passage of the "Adams Act" will be generally recognized as marking a new era in agricultural investigation. It not only opens up new possibilities to the experiment stations, but its passage indicates the widespread interest in scientific agriculture, which will serve to make their efforts more effective.

The new appropriation is a distinct tribute to the work and influence of the experiment stations, and to the place which they have won in the appreciation of the people. A few years ago it would have been well-nigh impossible. But the stations have demonstrated their usefulness to the satisfaction of the most skeptical, and through their publications and their public speaking have waged a great campaign of education whose influence has become very potent. The confidence now felt was reflected in not only a sympathetic but an aggressive attitude for the passage of the increased appropriation.

From the time Mr. Adams introduced his bill two years ago, it had the cordial support of representative farmers, their organizations, and the agricultural press. Rarely has a measure making a continuous demand upon the Treasury met with less opposition in Congress. Hardly a voice was raised against it on the floor of the House, and in the Senate there was unanimous consent to its consideration and no opposition to its passage on the final vote. As passed the act is practically in the form in which it was submitted at the beginning of this session of Congress. Great credit is due its author for the skill and devotion with which he labored for this measure, and prepared the way for its unanimous passage.

Great changes have come about since the Hatch Act was passed—greater and more far-reaching than we realize until we pause to compare the condition of knowledge then and now. At that time the practice of agriculture was governed to a very large extent by empirical rules. The subject was not differentiated either in the agricultural college or the experiment station, and apparently the need of such differentiation was not felt because there was not the necessary basis for it.

There were very few standard books dealing with the principles and practice of agriculture and horticulture. Farmers' institutes were largely social or political gatherings instead of schools for the farmers, and if a seed-corn special or a dairy special had been run it would have attracted small attention. The general attitude toward experimentation and science in agriculture was decidedly skeptical. The idea that there was something occult or which could not be fathomed or explained in successful agricultural practice still had a considerable hold.

The eight or ten experiment stations maintained in as many States received only small support from their States, and to a quite large extent were engaged in inspection work. A college or station dairy building, or an insectary, or an agronomic laboratory was as unheard of as a respiration calorimeter. The equipment was meager and the working force quite limited. In only twelve States had a need been felt for a fertilizer control, which to-day is exercised in thirty-four States and applies to an industry amounting to more than $50,000,000 a year. There was no feeding-stuffs control, no inspection of nursery stock or seeds or creamery apparatus or insecticide materials, and no laws for the control of San José scale or other insects and diseases dangerous to agriculture.

At that time there was no simple method for testing milk, as a means for measuring the value of individual cows and as a basis for paying for milk at creameries. The basic principles underlying dairying were far from being known—that cream ripening is due to special cultures of bacteria which affect the quality and the flavor of the product, that the cheese value as well as the butter value of milk is largely dependent on the fat content, that cheese ripening is due to well-defined organisms and conditions, that cold curing of cheese is not only practicable but a great safeguard to the product, and that many cases of inferior product are due to faults of the milk which may be avoided by the curd test. Sanitary and pasteurized milk were almost unknown; the various causes which contribute to unclean and unhealthy milk were but little understood.

It was not known that clovers and other legumes are able to store up the nitrogen of the air in their growth, much less that this ability is due to a symbiotic relation between the plants and bacteria on their roots; that atmospheric nitrogen may be made available to plants by several other means; and that nitrification and denitrification are very important processes in relation to plant nutrition, and are accomplished by micro-organisms in the soil whose activity is controlled by a variety of conditions. The theory of tillage and its value for conserving moisture was far from being understood, as were also the use of fertilizers and the requirements of crops under irrigation.

There was little conception of the possibilities of plant breeding and selection, to improve such common crops as corn and the cereals,

change their composition, and adapt them to different localities and purposes and a shorter season of growth. Dry farming as we now know it was not heard of, and the crops which have to a large measure made it a success had not been introduced or disseminated in this country. The theory and practice of silage making had not been worked out, and the place of silage in farm economy was only partially appreciated. The same was true of a wide range of feeding stuffs, and the effects of different feeds, most advantageous combination, the period of profitable fattening and many other matters relating to feeding were quite largely matters of tradition. We did not know that hens differ as greatly in productive power as milch cows, and that the egg-laying habit could be largely developed by selection.

We did not know that Texas fever could be eradicated, or that tuberculosis could be weeded out of a herd and animals inoculated against it; we had no conception of the extent to which plant diseases and injurious insects could be held in check by seed treatment, by spraying the crop, and by various other means which have been devised and have become a part of good farm practice. The country was not aroused to the dangers of depleting our forests, and there were no forest schools. Large amounts of by-products from various industries which are now turned to use for agricultural purposes were allowed to go to waste. We did not know that the date palm could be grown commercially in Arizona, macaroni wheats in the semiarid Northwest, alfalfa in the South and many parts of the East, and the sugar beet over a wide belt of country; that Alaska had any agricultural possibilities, or that an experiment station could be of great advantage to even the primitive agriculture of the range.

Some of the things which it was thought were known were supported by imperfect data, and the conclusions were far from secure. And most important of all, only a small proportion of what was known found application in the practice of the average farmers.

This remarkable advancement is, of course, not due to any single group of agencies. It is the combined product of a great variety of institutions all over the world, some of them working in pure science and others in its special applications. But in all of this modern development of a more rational and scientific basis for agriculture, the American experiment stations, and the National Department of Agriculture, which forms an integral part of the experiment station system in this country, have been a conspicuous and very essential factor.

Many classes of problems which the stations had to face nineteen years ago are now settled in most States. Questions of organization and the responsibilities of the States have worked themselves out. It has been shown that the farmers can be reached and their confidence won to such an extent as to form the basis for a substantial and influ-

ential public sentiment, which will give encouragement and support to the stations in their legitimate work and prevent outside interference. This in reality is one of the most remarkable results of the experiment station movement, and it is by no means confined to the older States of the East where agriculture is more highly developed and specialized. The newer States, with no deeply grounded traditions of farm practice and with crude methods and conditions, have been quite as ready to embrace the work of the stations and to look to them for advice and aid.

In no other country does the experiment station occupy the same position in its relations to the people that it does in America. In the form in which we know it, it is distinctly American. It is this that makes it of special interest to foreign visitors; but transplanted to another country it becomes a quite different thing, because of the difference in environment. It is a product of American institutions and American ideals. The great value of its services in the past is attested on every hand, but those who have studied the station movement in its relations to future development feel that an even more important field is open to it.

This field the Adams Act prepares the stations to occupy. It will relieve them in some directions but will impose new responsibilities upon them. To a large extent it provides for a new order of work only possible to a limited extent before. The Adams Act differs from the Hatch Act in the more restricted application to be made of the funds. It provides specifically for the fundamental investigations of original character which the work of the past few years has brought out such a glaring need of. It is in many respects modeled on the second Morrill Act, being "for the further and more complete endowment, support, and maintenance" of the stations, to the end that they may conduct "original researches or experiments bearing directly on the agricultural industry of the United States."

The evident intention was to provide a research fund, and not merely to supplement the Hatch fund. The latter is more general in its provisions, and is applicable to a wider range of uses. While it has been a great stimulus to agricultural investigation, it has not been practicable, perhaps not advisable, to restrict it except in a quite general way. It has been employed for many purposes for which the Adams fund obviously can not be. This difference between the Hatch and Adams acts may not always be apparent to the general public. It is all the more important, therefore, that the distinction should be clear in the minds of those charged with station work.

The great service which the stations have been able to render to agriculture is a product of investigation and research, more or less remote, carried on somewhere and at some time, which has become a part of the sum total of our knowledge. The more elementary testing

and experimenting, important as it has been, has been merely the attempt to apply to local conditions and needs or to introduce into practice these general principles which have been previously worked out, together with the result of accumulated experience. The station worker who has not taken account of these facts has been either an imitator or an indifferent experimenter.

The new fund will call for sharper discrimination between different kinds of work. If held strictly to the purposes specified in the act it will give a great opportunity for placing the American stations on a high level as research agencies, and give them a leadership in developing the science of agriculture. It is the greatest opportunity for continued systematic research along agricultural lines which has ever been presented in any country, and this opportunity and the realization of the ultimate importance of investigation should be the inspiration of every station man and every friend of agricultural advancement. It should be a strong incentive to the careful choice of problems to be investigated, thorough and exhaustive work in their solution, and the securing of permanent and far-reaching results.

The best use of the fund in the different States will call for wise administration and the selection of men with a genius for agricultural investigation. The Adams fund roll might well be regarded as in a sense an honor roll, made up of men who have been selected on account of demonstrated special ability and qualifications for research work. The standard should be set as high as the available supply in this country will permit, and the outlook should furnish an additional incentive to men with taste and ability for research to prepare themselves thoroughly for their work.

Many of the stations have been planning in advance lines of investigation to be inaugurated under the new act. Many of these lines were not conceived of when the Hatch Act was passed, and would have been impossible in the state of knowledge then existing. This indicates how opportune the new grant is, and shows how wise the provision to confine it to advanced work. The granting of a comparatively small initial appropriation, with an annual increase for five years, will allow the stations to adjust themselves to the new work and to plan economically.

The Hatch fund will continue to cover some of the elementary work which will appeal more immediately to the farmers' needs, the adaptation of principles to local conditions, and the working out of improved methods. The research under the new act will extend the basis for demonstration and verification experiments leading to general improvement of farm practice in many directions. But more and more the States will be called upon to make provision for the local demonstrations intended to bring facts home to the farmer, the cooperative

experiments to arouse his interest and teach him how to apply results, and propaganda work looking to the establishment of special agricultural industries, as it does now for the farmers' institutes and for branch stations.

This added responsibility of the States was brought out in the report of the committees in Congress in presenting the Adams bill, which states that while the bill places the responsibility for additional work upon the various stations, it "will necessitate a corresponding increase of appropriation from the various States because of the additional work provided for."

This is further emphasized in the circular letter of the Secretary of Agriculture, relating to the administration of the Adams Act. In this the Secretary says: "The increased liberality of the Federal Government in providing for the endowment of research and experimentation in agriculture should be a further incentive to the States and local communities to supplement these funds for the extension of demonstration experiments, farmers' institutes, agricultural colleges, schools, and courses of instruction, and the general education of the rural communities along industrial lines, in order that the masses of our farmers may be so educated from early youth that they will appreciate the benefits of original research and experimentation as applied to agricultural problems, and be able to appropriate in the most effective manner for their own benefit and the general welfare of the Nation whatever practical results are obtained from the work of the agricultural experiment stations."

In this way the greatest permanent benefit will be conferred, and agriculture will more rapidly be placed upon an intelligent and scientific basis.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Some observations on the determination of citric-acid soluble and total phosphoric acid in Thomas slag, F. MACH (*Landw. Vers. Stat., 63 (1905), No. 1-2, pp. 81-91; abs. in Chem. Centbl., 1906, I, No. 1, pp. 85, 86; Jour. Chem. Soc. [London], 90 (1906), No. 519, II, p. 50*).—Comparative tests of Wagner's method and of the official method of the German association of experiment stations for determining citric-acid soluble phosphoric acid are reported.

The results by the two methods as a rule agreed quite closely, but occasionally the Wagner method gave higher results than the official method, in which silica is removed before precipitation of the phosphoric acid, and higher than the molybdic method, especially in slags rich in silica. The method of evaporating only to a sirupy consistency proposed by A. Bömer gave similar results. The thorough removal of silica previous to precipitation of phosphoric acid is considered essential to accuracy.

The Schenke modification of the citrate method for determining total phosphoric acid (E. S. R., 17, p. 6) was found to give results in the author's opinion too high, indicating that it should be further tested before it is substituted for the ordinary method.

A simple method of determining phosphoric acid, potash, sodium, calcium, and magnesium in hydrochloric-acid soil solutions, H. NEUBAUER (*Landw. Vers. Stat., 63 (1905), No. 1-2, pp. 141-149; abs. in Chem. Centbl., 1906, I, No. 1, p. 83*).—The method described is based upon the fact that when the hydrochloric-acid solution of a soil is evaporated to dryness and carefully heated the iron and aluminum chlorids are converted into insoluble oxids, the calcium and magnesium chlorids are but slightly affected, and the chlorids of the alkalis are not altered.

The evaporation to dryness (with addition of a small amount of calcium carbonate if this constituent is deficient in the soil) removes iron, phosphoric acid, and silicic acid, and furnishes a solution in which potash and soda may be determined directly by the author's method.[a] Phosphoric acid is determined by the molybdic method in the residue from the potash determination. For the determination of calcium and magnesium another portion of the hydrochloric-acid solution is evaporated to dryness and heated until all trace of acid disappears and calcium is determined in the water extract of the residue by precipitation with ammoniacal ammonium oxalate and magnesium in the filtrate from the calcium precipitate by precipitation with sodium phosphate.

The method is not reliable in case of soils containing large amounts of sulphates. There is danger of injury to platinum dishes due to the formation of free chlorin in the heating of the chlorids in the residue from evaporation. The results of the potash determinations are not very satisfactory in case of soils poor in potash. The addition of a small amount of potash-free calcium chlorid to the soil solution before evaporation was found to increase the accuracy of the potash determinations.

---

[a] Ztschr. Analyt. Chem., 39 (1900), p. 481.

Titanium, H. PELLET and C. FRIBOURG (*Ann. Sci. Agron., 2. ser., 10 (1905), II, No. 1, pp. 20–84*).—This article deals with the properties of titanium and its different compounds, studies of different methods employed in the separation and determination of titanic acid and of the presence and determination of titanic acid in soils and plants, especially in sugar cane and sugar beets.

The authors found 2 per cent of titanic oxid in an Egyptian soil used for the cultivation of sugar cane and 0.47 per cent in a French soil used for the culture of sugar beets. They refer to Maxwell's work, indicating the occurrence of considerable amounts of titanic oxid in sugar cane and report the occurrence of 0.17 per cent of this substance in the ashes of sugar cane which contained, however, a small amount of soil. In ashes of sugar cane and sugar beets prepared with great care they were not able to find any titanium.

The determination of titanic acid in soils and ash of plants, H. PELLET and C. FRIBOURG (*Ann. Chim. Analyt., 10 (1905), No. 11, pp. 413–416; Bul. Assoc. Chim. Sucr. et Distill., 23 (1905), pp. 67–71; abs. in Chem. Centbl., 1905, II, No. 16, pp. 1193, 1194*).—A colorimetric method and a gravimetric method are described. The first is based upon fusion with hydrofluoric acid and hydrogen potassium sulphate, sulphuric acid solution of the fusion being treated with hydrogen peroxid and tested in comparison with solutions of known strength in a Josse colorimeter. The second method is based upon fusion in a similar manner, partial neutralization with potassium hydroxid, and boiling with hydrochloric acid, the titanate precipitated being washed with a 2 per cent potassium carbonate solution.

The influence of the presence of titanium on the determination of aluminum in presence of iron oxid and phosphoric acid by the principal methods employed at the present time, H. PELLET and C. FRIBOURG (*Ann. Chim. Analyt., 10 (1905), No. 11, pp. 416–420*).—Investigations are reported which show that the presence of titanic acid affects the accuracy of the Carnot method for aluminum, and all others in which aluminum phosphate is precipitated, and should be determined by the colorimetric method noted above and correction made accordingly.

Occurrence of alumina in plants, H. PELLET and C. FRIBOURG (*Ann. Chim. Analyt., 10 (1905), pp. 373–376; abs. in Jour. Chem. Soc. [London], 88 (1905), No. 518, II, pp. 860, 861*).—Alumina was found in only very minute quantities in sugar cane and sugar beets. In determining the alumina, the hydrochloric-acid solution freed from silica in the usual way was neutralized with ammonia and oxidized by the addition of a few crystals of potassium chlorate. Ammonium phosphate and ammonium thiosulphate were then added in the proportion of 2 gm. of the former to 10 gm. of the latter and the mixture boiled for 15 minutes. Acetic acid in proportion of 15 gm. was afterwards added, the precipitate of aluminium phosphate being collected on a filter, ignited, and weighed.

Methods of organic analysis, H. C. SHERMAN (*New York and London: The Macmillan Co., 1905, pp. XII+245*).—In this volume, which is designed as a text-book for college and university use, it has been the author's purpose to give introductory instruction in organic analysis with special reference to plant and animal substances and their manufactured products.

The greater part of the book is devoted to quantitative methods for food materials and related substances, a feature of the work being the numerous references to the publications of the Association of Official Agricultural Chemists and the attempt to follow as far as possible the nomenclature in such publications.

As a whole the work constitutes a valuable handbook for students of analytical chemistry, particularly as related to carbohydrates, acids, oils, fats, waxes, fatty oils, butter, soaps and lubricants, proteids and cereals, milk, preservatives, etc. Throughout the text numerous references are made to the literature of the subject and the volume also includes a complete index.

A new method for the quantitative estimation of sugar with the Zeiss immersion refractometer, B. WAGNER and A. RINCK (*Chem. Ztg., 30 (1906), No. 5, pp. 38, 39*).—The authors claim that the use of the immersion refractometer for determining sugar is more accurate, more rapid, and more economical of time and material than gravimetric methods. The possibilities of the method for the determination of calcium, aluminium, iron, zinc, etc., are also spoken of.

Globulin, J. MELLANBY (*Jour. Physiol., 33 (1905), No. 4-5, pp. 338-373, figs. 16*).—The conclusions drawn from a series of investigations on the solution of globulin by neutral salts, the precipitation of globulin from such solutions, and related questions follow:

"Solutions of globulin by a neutral salt is due to forces exerted by its free ions. Ions with equal valencies, whether positive or negative, are equally efficient, and the efficiencies of ions of different valencies are directly proportional to the squares of their valencies.

"The amount of globulin dissolved by a given percentage of neutral salt is directly proportional to the strength of the original globulin suspension.

"The precipitation of globulin from solution in neutral salts by neutral salts depends upon a molecular combination between the salt and globulin, the compound so formed being stable only in excess of the combining salt. Precipitation by salts of the heavy metals depends upon the formation of a stable salt globulin compound.

"Solution of globulin by acids or alkalies is of the nature of a chemical combination. The relative solvent efficiencies of strong acids and alkalies are of the same order as their chemical avidities."

The cleavage of edestin of cotton seed by pancreatic juice, E. ABDERHALDEN and B. REINBOLD (*Ztschr. Physiol. Chem., 46 (1905), No. 1-2, pp. 159-175*).—When cleavage was induced by treating the edestin of cotton seed with pancreatic juice, the proportion of dialyzable material not precipitated by phosphotungstic acid increased with the time of the reaction, while the proportion of the material precipitated by phosphotungstic acid increased at first and then decreased. Tyrosin, glutaminic acid, leucin, alanin, and aspartic acid and trytophan were isolated from the cleavage products; also traces of phenylalanin. No glycocoll nor α-pyrrolidin carbonic acid was found.

Carbon tetrachlorid with special reference to its use as a solvent in the extraction of fat and in similar ways, B. M. MARGOSCHES (*Der Tetrachlorkohlenstoff, unter besonderer Berücksichtigung seiner Verwendung als Lösungsbzw. Extraktionsmittel in der Industrie der Fette und verwandter Gebiete. Stuttgart: Ferdinand Enke, 1905, pp. 115; rev. in Österr. Chem. Ztg., 8 (1905), No. 24, p. 571*).—A monograph on carbon tetrachlorid summarizing the literature from a historical, chemical, and technological standpoint. The work as a whole constitutes a bibliography of the subject.

A laboratory handbook for the analysis of milk, butter, and cheese, J. R. EVANS (*[New York], 2. ed., pp. 60*).—This is a brief outline of useful methods with no attempt at interpreting results. The author states in the preface that "during the past year a rigid investigation was undertaken for the purpose of determining the comparative value of the various 'milk testers,' with the result that the lactoscope, creamometer, pioscope, lactobutyrometer, and the lactometer, when used alone, were found absolutely worthless in the testing of a milk."

The application of "sin-acid" butyrometry to sheeps', goats', and cows' milk, C. BEGER (*Milchw. Zentbl., 1 (1905), No. 12, pp. 547-551*).—Comparative determinations by the Gerber and the Sichler non-acid methods on the three kinds of milk are reported.

Considerable difficulty was experienced in testing milk preserved with formalin by the Sichler method. For ordinary purposes the non-acid method in its present form is not considered as satisfactory as the Gerber method, and for the chemist the use of acid as in the Gerber method can scarcely be considered a disadvantage.

Contribution to the cryoscopic examination of milk, O. ALLEMANN (*Landw. Jahrb. Schweiz, 19 (1905), No. 8, pp. 499-502*).—Cryoscopic examinations of 23 samples of milk of known purity showed on an average a freezing point of −0.571° C., while 11 samples to which 2 per cent of water had been added showed an average freezing point of −0.554°, 11 samples to which 5 per cent of water had been added −0.536°, 11 samples to which 10 per cent had been added −0.500°, and 11 samples to which 20 per cent had been added −0.457°.

This method in the hands of the expert analyst is believed to be very valuable in the detection of added water in milk, due attention being paid to the acidity of the milk and the possibility of the addition of preservatives which might affect the results. On account of the skill and time required, this method is not considered as useful in routine work as determinations of the specific gravity and fat.

A method for the determination of hydrogen peroxid in milk, together with some observations on the preservation of milk by this substance, S. AMBERG (*Jour. Biol. Chem., 1 (1906), No. 2-3, pp. 219-228*).—The author has made use of the method proposed by Richardson and which is based upon the color reaction produced by a solution of titanium hydrate in sulphuric acid in the presence of hydrogen peroxid. The method as applied by the author to milk was found to be accurate when the hydrogen peroxid was present in quantities even as small as 1:5,000. It is noticed that salicylic acid causes a color reaction which can scarcely be distinguished from that product by hydrogen peroxid.

It was found that boiled milk uses up a certain amount of hydrogen peroxid independently of catalytic and bacterial action, and the idea is advanced that this may be due to the production of reducing substance by boiling. The literature relating to the use of hydrogen peroxid for the preservation of milk is reviewed and the objections which have been raised to this method are noted. The author concludes that although the efficiency of hydrogen peroxid in sterilizing milk in all cases has not been established, and although the amount required for preserving milk for any given length of time is uncertain, the harmlessness of the method seems to justify its trial as a milk preservative.

The identification of boric acid, O. VON SPINDLER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 8, pp. 478-482, fig. 1*).—Recently published data on the determination of boric acid are summarized, and a new form of apparatus described for conveniently determining boric acid by the flame test.

Formaldehyde and its reactions, J. SCHUCH (*Ztschr. Landw. Versuchw. Oesterr., 8 (1905), No. 11, pp. 1058-1060*).—The author tested several methods for the determination of formaldehyde concluding that the Arnold and Mentzel method is the best for the detection of formaldehyde in wine.

METEOROLOGY—WATER.

Report of the Chief of the Weather Bureau for 1905, W. L. MOORE (*U. S. Dept. Agr., Weather Bur. Doc. 338, pp. 37*).—This report contains a review of 10 years' work of the Bureau under the present chief, as well as an account of work of the year 1905, with recommendations.

It is stated that the Bureau "has made such progress in its internal discipline and in the results accomplished for the benefit of the farmer, the mariner, the shipper, the manufacturer, and the seeker after health or pleasure, that there is no weather service anywhere in the world comparable with it." It has developed and put into effect a fair, yet rigid, discipline for the control of its personnel and a system of study and examination which develops the intellectuality of those who receive advancement. "With such a discipline it has, with rare exceptions, given timely warning of the coming of injurious changes in temperature, and allowed no important storms or floods to come unannounced."

It has encouraged the study of meteorology in educational institutions by allowing its scientists, outside of their official duties, to deliver courses of lectures to students, so that there are now twenty institutions of learning where meteorology forms a part of the curriculum, thereby giving preliminary training to the young men who, in after years, will succeed to the duties now performed by the meteorologists of the Government.

Three years ago the Bureau began the establishing, at Mount Weather, Va., of an institution devoted purely to meteorological research. This observatory was established to enable the Bureau to raise its work in meteorological research to the same plane as that occupied by its work in practical meteorology. The plant is especially adapted to atmospheric research and is equipped with a physical laboratory in which all questions which yield to treatment by experiment as distinct from pure observation can be investigated. An outline is given of lines of investigation which may be profitably undertaken in the laboratories of the Mount Weather observatory.

Monthly Weather Review (*Mo. Weather Rev., 33 (1905), Nos. 10, pp. 433–470, fig. 1, charts 10; 11, pp. 471–514, fig. 1, charts 11*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of October and November, 1905, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 10.—Special contributions on The Ziegler Relief Expedition, by O. L. Fassig; Standing Clouds Among the North Carolina Mountains, by F. W. Proctor; Sounding and Pilot Balloons over the Ocean, by Prince of Monaco; Weather Bureau Cipher Codes, by E. B. Garriott; and notes on meteorology of the planet Mars. Mr. Harry B. Wren, Eiffel's "Études pratiques," methods of teaching meteorology, the rainfall of Mexico, temperatures on Mount Rose, Nev., protection from frost, publication of thermograms in facsimile, structure of hailstones, the pagoscope versus the daily weather map, Weather Bureau men as educators, meteorology in colleges and universities, meteorology in German universities, unusually early snow in Alaska, and the deflection to the right (illus.).

No. 11.—Special contributions on The Importance of a Well Written Synopsis of Weather Conditions, by N. R. Taylor; Results of the Work Done at the Aeronautical Observatory of the Royal Prussian Meteorological Institute, from January 1, 1903, to December 31, 1904, by S. Hanzlik; Highest Kite Ascension, by C. F. Marvin; The Rainfall of China and Korea (illus.), by T. Okada; The Development of Meteorology in Australia, by A. Noble; Storm Warnings for Lake Vessels, by E. B. Garriott; and notes on a guide to the observation of earthquakes, Indian summer, a lecture on snow crystals, physical societies and journals, cold and heat, meteors—their incandescence and their noise, meteorological literature in the public libraries, standard time at Key West, influence of location on the winds, and a mistake about atmospheric dust.

Meteorology and climatology, W. TRABERT (*Meteorologie und Klimatologie. Leipsic: Deuticke, 1905, pp. 127, figs. 37; rev. in Nature [London], 73 (1905), No. 1885, p. 149*).—This book forms part 13 of Klar's "Die Erdkunde," and outlines the general principles of meteorology and their application to the study of climate. It deals with the meteorological elements and the making and reducing of observations, atmospheric physics, the distribution of temperature and its variations, the circulation of the atmosphere, evaporation and condensation, weather and climate, including weather forecasting, types of climate, and the climatic characteristics of the main land divisions of the globe.

Meteorological chart of the Great Lakes, A. J. HENRY and N. B. CONGER (*U. S. Dept. Agr., Weather Bur., Met. Chart Great Lakes, 1905, No. 1, pp. 19, pl. 1*).—This is a summary of observations on the meteorological conditions of the winter of 1904–5 in the lake region, with notes on the opening of the navigation season of 1905,

ice during the winter of 1904-5 at different points on the Great Lakes, and display of storm signals on the lakes.

Temperature and relative humidity data, W. B. STOCKMAN (*U. S. Dept. Agr., Weather Bur. Bul. O, pp. 29, charts 2*).—This pamphlet consists of a series of tables which show for each month of the year and for each Weather Bureau station that has been in operation at least six years, the highest and lowest temperatures, respectively, that have been observed from the beginning of observations until the end of 1904; the monthly and annual mean maximum and mean minimum temperatures, and monthly and annual mean relative humidity.

A preliminary investigation of the more important features of the meteorology of southern Asia, the Indian Ocean, and neighboring countries during the period 1892-1902, J. ELIOT (*Indian Met. Mem., 16 (1905), pt. 2, pp. 181-307 + XLVII, pls. 22; rev. in Nature [London], 73 (1905), No. 1884, pp. 136, 137*).—It is stated that the period covered by this report "was unique in the meteorology of India for the magnitude and persistence of the variations of rainfall, cloud, humidity, and temperature from the normal."

For the purposes of discussion the period covered is divided into 2 parts, abnormal in opposite directions, (1) 1892-1894, characterized by excess of rain, cloud, and humidity, and a reduced temperature, and (2) 1895-1903, characterized by deficient rainfall, less cloud, drier air, and an average temperature above the normal. The normal annual rainfall for the period, calculated from data from 450 stations, was 41.09 in. The normal rainfall for the 3 years above noted as abnormally wet was 123 in., the total rainfall for the period being 143.5 in., an excess of 20.5 in. The total rainfall for the 8 years 1895-1902 was 303.8 in., a deficiency of 24.9 in. It appears that all seasons of the year were affected by these abnormal conditions.

Not only India, but other countries—Australia and South Africa—depending upon the Indian Ocean for their rain, were in excess during 1892-1894 and deficient during 1895-1902. Long-period barometric variations were similar in direction, amount, and epoch for all India. There was apparently a 2-year period of barometric oscillation. Observations with a black bulb thermometer indicate that during 1891-1897 there was an excess of solar radiant energy and during 1898-1902 there was a deficiency. The period of deficient rainfall was characterized by droughts and famines.

An appendix contains reports on two of the latter (in 1897 and 1900) as well as detailed data relating to seasonal rainfall, rainy days, pressure, and dates of commencement and ending of monsoon rains.

British rainfall, 1904 (*London: Edward Stanford, 1905, pp. 88 + 279, pls. 8, figs. 14*).—This, the forty-fourth annual volume on British Rainfall, is compiled by H. R. Mill, and is based upon the records of 3,982 rain gages distributed throughout Great Britain and Ireland.

It includes "(1) a report touching on the work of the rainfall organization; (2) original articles discussing the rainfall of Ben Nevis, the driest Octobers on record, and the twenty-four years' records of duration of rainfall at Camden Square; (3) tables of duration of rainfall, amount of evaporation, and representative records of daily rainfall (a new feature) at selected stations during 1904; (4) an account of the staff of observers, and a list of the changes in the stations; (5) a record of the losses of observers by death, with a few biographical notes; . . . (6) the observers' remarks on rainfall and weather; (7) a discussion of heavy falls of rain with a minute investigation of the distribution of rainfall on the wettest days; (8) discussions of droughts, rainy spells, number of rainy days, and intensity of rainfall at selected stations; (9) a general discussion of the relation of the monthly and annual rainfall to the average; and (10) the general table of annual rainfall at all stations, together with the names of the observers or responsible authorities."

The report records the discontinuance, October 1, 1904, of the observations on Ben Nevis, the highest possible site in the British Isles, which began in 1883, as well as at Fort Williams, 4 miles away and 4,400 ft. below the summit of Ben Nevis.

Chlorin in rain water (*Agr. Students' Gaz., n. ser., 12 (1905), No. 5, p. 172*).—This is a brief summary for the 6 months and for the year ended September 30, 1905, of the usual observations at the Royal Agricultural College at Cirencester on rainfall and its chlorin content.

"The rainfall for the 6 months was 13.44 in., falling on 83 days; it contained a mean of chlorids equivalent to 0.277 gr. sodium chlorid per gallon, i. e., equal to a deposit of 11.96 lbs. of common salt per acre. The rainfall for the 12 months was 23.66 in., on 172 days, and it contained chlorids equal to 26.8 lbs. of common salt per acre."

Composition of Barbados rainfall (*Rpt. Agr. Work, Imp. Dept. Agr. West Indies, 1902–1904, pt. 1, p. 3*).—A table is given which shows the total amount and contents of chlorin, total nitrogen, nitrogen as ammonia, and nitrogen as nitrates in the rainfall at Dodds during the period from December, 1902, to May, 1904. The total rainfall during the period was 103.62 in., supplying approximately 272 lbs. of chlorin and 15 lbs. of nitrogen per acre.

A contribution to the rainfall régime of the region of Boulogne, G. Ventura (*Gior. Gen. Civ., 1905, Jan.*).—This report gives an account of studies on the relation of the rainfall to canal and drainage systems in a part of this region.

Rainfall in the agricultural districts, G. G. Bond (*Queensland Agr. Jour., 16 (1905), No. 3, p. 288*).—A table is given which shows the total rainfall for each month from October, 1904, to October, 1905, inclusive, in 41 agricultural districts of Queensland.

Thunder and lightning, C. Flammarion, trans. by W. Mostyn (*London: Chatto & Windus, 1905, pp. 281; rev. in Nature [London], 73 (1905), No. 1887, p. 196*).—This is an abridged translation of Flammarion's *Les phénomènes de la foudre*. The greater part of the book is devoted to the effects of lightning strokes on man, animals, trees, plants, metals, houses, etc.

The pulse of the atmospheric circulation, W. N. Shaw (*Nature [London], 73 (1905), No. 1886, pp. 175–177, fig. 1*).—This article discusses the relation between the pulsations of the southeast trade wind as measured during a long period at St. Helena and the rainfall of northwestern Europe. Such a relation is believed to be clearly shown by the available data which are summarized and charted.

Investigation of the upper air (*Nature [London], 73 (1905), No. 1885, p. 162*).—A brief announcement regarding the proposed work of the British Meteorological Committee in the investigation of the upper air by kites and other means.

Improved methods for finding altitude and azimuth, geographical position, and the variation of the compass (*U. S. Dept. Agr., Weather Bur. Doc. 336, pp. 8, figs. 7*).—The methods proposed by St. Hilaire, Souillagouët, and Littlehales are discussed and explained with tables and charts.

Daily river stages at river gage stations on the principal rivers of the United States. Part VII, for the years 1900, 1901, 1902, 1903, and 1904, H. C. Frankenfield (*U. S. Dept. Agr., Weather Bur. Doc. 339, pp. 728*).—"This volume constitutes the seventh part of the series of river gage readings, the publication of which was begun by the Signal Service and has been continued by the Weather Bureau. The previous volumes are as follows: Part I. Stages of the Ohio River and of its principal tributaries, 1858 to 1889. Part II. Stages of the Mississippi River and of its principal tributaries, except the Ohio River, 1860 to 1889. Part III. Stages of water at miscellaneous river stations in California, Oregon, North Carolina, etc., 1875 to 1889. Part IV. Daily river stages at river gage stations on the principal rivers of the United States for the years 1890, 1891, and 1892. Part V. Daily

river stages at river gage stations on the principal rivers of the United States for the years 1893, 1894, and 1895. Part VI. Daily river stages at river gage stations on the principal rivers of the United States for the years 1896, 1897, 1898, and 1899."

A report on the underground waters of Louisiana, W. C. STUBBS, G. D. HARRIS, A. C. VEATCH, ET AL. (*Geol. Survey La. Bul. 1, pp. VIII + 164, pls. 10, figs. 12*).—This bulletin is divided into 2 parts, (1) the underground waters of southern Louisiana and (2) the underground waters of northern Louisiana and southern Arkansas. The work on the underground waters of Louisiana was begun by the State Geological Survey in 1899, and earlier reports on the subject have already been noted (E. S. R., 14, p. 428; 16, p. 722).

The first part of this bulletin is substantially a reprint of Water Supply and Irrigation Paper No. 101 of the U. S. Geological Survey (E. S. R., 16, p. 722). It deals with origin of artesian and deep-well waters in southern Louisiana, topography and stratigraphy of the region, subdivisions based on underground water conditions, well statistics, variations in flow and pressure head shown by wells in southern Louisiana, well drilling, and pumping.

The second part of the bulletin is a preliminary report on work carried on in 1902 and 1903 in Louisiana and adjoining States by A. C. Veatch, partially in the employ of the Louisiana State Survey and partly as assistant geologist to the U. S. Geological Survey. It gives a summary of the main results obtained in a study of the topography, stratigraphy, geological formations, and water horizons of northern Louisiana. A dictionary of altitudes in the same region is given in an appendix.

On the influence of summer rains on the flow of springs, HOULLIER (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 23, pp. 972, 973; abs. in Rev. Sci. [Paris], 5. ser., 4 (1905), No. 25, p. 783*).—This article discusses briefly the various factors which modify the relations between the rainfall and the flow of springs, such as the permeability of the soil, temperature, and movement of winds, cultural conditions, etc., of the basin feeding the springs.

Water softening at Oberlin, Ohio, W. B. GERRISH (*Engin. Rec., 52 (1905), No. 15, pp. 412, 413; abs. in Jour. Amer. Chem. Soc., 27 (1905), No. 12, Rev., p. 676, 677*).—A water-softening plant in which sodium carbonate and calcium hydroxid are used to remove hardness, due to carbonates and sulphates of calcium and magnesium, is described.

The sterilization of water by ozone, A. STEENS (*Engin. Rec., 53 (1906), No. 1, pp. 31, 32, figs. 4*).—This article describes the system proposed by Marmier and Abraham, in which water to be sterilized is passed through a vertical cylinder filled with concentrated ozone in such a way as to secure a thorough mingling of gas and water. The method is claimed to be very efficient.

Purification of water by copper sulphate, D. D. JACKSON (*Municipal Engin., 29 (1905), No. 4, pp. 245, 246; abs. in Jour. Amer. Chem. Soc., 27 (1905), No. 12, Rev., p. 675*).—An account is given of the successful use of copper sulphate, 1 part in 2,000,000 of water, to remove algal growths in ponds.

In experiments with *Bacillus coli communis* and *B. typhi abdominalis* it was found that 1 part of copper sulphate to 50,000 parts of water was required to kill the germs when fresh and virulent. One part of the sulphate in 1,000,000 of water will greatly attenuate the germs and render them much less harmful in time of typhoid epidemics. One part in 2,000,000 of water destroys the germs with the attenuation usually found in water. One part in 50,000, and even 1 part in 1,000,000, can, however, be detected by taste and might affect the consumer.

A new method for detecting pollution of drainage water, water of streams, and drinking water, L. HEIM (*Österr. Chem. Ztg., 8 (1905), No. 22, p. 521*).—An asbestos filter which has been successfully used for removing suspended matter from water so that the colorimetric determinations may be more accurately made is described.

Water supply and sewerage (*Ann. Rpt. Bd. Health Mass., 36 (1904), pp. 1-295*).—This is the annual report of the State Board of Health to the legislature, and includes accounts of advice to cities and towns regarding water supply, ice supplies, sewerage and sewage disposal, and pollution of ponds and streams; examination of water supplies; examination of rivers; water-supply statistics; and experiments on the filtration and purification of sewage and water at the Lawrence Experiment Station in 1904.

Examinations with reference to free and albuminoid ammonia, nitrates and nitrites, oxygen consumed, hardness, suspended matter, residue on evaporation, color, and odor are reported for a large number of samples of water from the water supplies of various Massachussetts towns, as well as similar data for water of various streams in the State. Data are also given showing the relation of rainfall to flow of streams.

The reports on experiments in purification of sewage present a large amount of data bearing on the storage of nitrogen in and removal from filters; nitrogen-disposal efficiency; loss of nitrogen in case of different kinds of filters; the relation of bacteria to the operation of filters and to sewage purification in general; and the bacteria in septic sewage and in the effluents from filters operated with septic sewage (E. S. R., 17, p. 300).

The more important conclusions reached are as follows:

"(1) With new sand filters a smaller percentage of the applied nitrogen appears in the effluent than when the filters have been operated for a considerable period.

"(2) With filters producing eminently satisfactory purification . . . the average amount of nitrogen appearing in the effluents as nitrates is but little more than 50 per cent of the nitrogen in the applied sewage.

"(3) This being so, it is clear that, if a filter is not ultimately clogged by stored nitrogenous organic matter, either removal of this matter must be resorted to, together with a removal of some of the filtering material, or a removal by bacterial actions independent of and differing from those of nitrification must be depended upon.

"(4) Much of the increase of unoxidized nitrogen in the effluent of the sand filters has been due to the increase of applied nitrogen year by year and the accumulation of stable organic matter in the filter.

"On account of the application of this larger amount of nitrogen two results ensue: (1) An amount of nitrogen in solution greater than can be easily and completely changed by bacterial action during the period of passage of the sewage through the filter, and (2) an amount of stable organic matter in suspension in the sewage is strained out, and, accumulating in the upper sand of each filter, causes unfavorable conditions, especially in winter, on account of the resultant increased compactness of these upper layers.

"Differing bacterial flora in the filter due to increase in stored organic matter and continued use of the filter may also be an important factor."

The use of copper sulphate at rates varying from 1 part to 1,130,000 parts of water to 1 part to 578,000 parts of water in connection with sand filters resulted in a marked decrease of bacteria in the water and in some cases in the total extermination of *Bacillus coli communis*. Sulphate of alumina used in similar manner produced like though less pronounced germicidal effects.

The bacteria of the air, water, and soil, E. Bodin (*Les bactéries de l'air, de l'eau et du sol. Paris: Masson & Co.; Gauthier-Villars* [*1905*], *pp. 197, figs. 2*).—This book forms one of the volumes of the *Encyclopédie scientifique des aide-mémoire* published under the direction of Léauté, and summarizes the more important facts relating to the bacteriology of the air, water, and soil.

SOILS—FERTILIZERS.

Field operations of the Bureau of Soils, 1904 (sixth report), M. WHITNEY ET AL. (*U. S. Dept. Agr., Field Operations of the Bureau of Soils, 1904, pp. 1159, pl. 1, figs. 45, maps 53*).—This report contains a general review of the work of the Bureau of Soils during 1904 and a discussion of the significance and uses made of the soil surveys, by the Chief of the Bureau, together with detailed accounts of the following surveys:

Soil Survey of Rhode Island, by F. E. Bonsteel and E. P. Carr; Soil Survey of the Vergennes Area, Vermont-New York, by H. J. Wilder and H. L. Belden; Soil Survey of the Auburn Area, New York, by J. E. Lapham and H. H. Bennett; Soil Survey of Adams County, Pennsylvania, by H. J. Wilder and H. L. Belden; Soil Survey of Appomattox County, Virginia, by T. A. Caine and H. H. Bennett; Soil Survey of Lancaster County, South Carolina, by A. S. Root and L. A. Hurst; Soil Survey of the Orangeburg Area, South Carolina, by F. Bennett and A. M. Griffen; Soil Survey of the Charleston Area, South Carolina, by F. E. Bonsteel and E. P. Carr; Soil Survey of Dodge County, Georgia, by C. W. Ely and A. M. Griffen; Soil Survey of the Bainbridge Area, Georgia, by E. O. Fippin and J. A. Drake; Soil Survey of the Gainesville Area, Florida, by T. D. Rice and W. J. Geib; Soil Survey of Macon County, Alabama, by H. J. Wilder and H. H. Bennett; Soil Survey of Sumter County, Alabama, by W. G. Smith and F. N. Meeker; Soil Survey of the Jackson Area, Mississippi, by J. O. Martin and O. L. Ayrs; Soil Survey of the Biloxi Area, Mississippi, by W. E. Hearn and M. E. Carr; Soil Survey of De Soto Parish, Louisiana, by G. B. Jones and La M. Ruhlen; Soil Survey of Anderson County, Texas, by W. T. Carter, jr., and A. E. Kocher; Soil Survey of the Austin Area, Texas, by A. W. Mangum and H. L. Belden; Soil Survey of the San Antonio Area, Texas, by T. A. Caine and W. S. Lyman; Soil Survey of Lawrence County, Tennessee, by C. N. Mooney and O. L. Ayrs; Soil Survey of the Greeneville Area, Tennessee-North Carolina, by C. N. Mooney and O. L. Ayrs; Soil Survey of Warren County, Kentucky, by T. D. Rice and W. J. Geib; Soil Survey of the Wooster Area, Ohio, by T. A. Caine and W. S. Lyman; Soil Survey of Coshocton County, Ohio, by T. D. Rice and W. J. Geib; Soil Survey of the Munising Area, Michigan, by T. D. Rice and W. J. Geib; Soil Survey of the Saginaw Area, Michigan, by W. E. McLendon and M. E. Carr; Soil Survey of the Alma Area, Michigan, by W. E. Hearn and A. M. Griffen; Soil Survey of the Owosso Area, Michigan, by A. W. Mangum and C. J. Mann; Soil Survey of Marshall County, Indiana, by F. Bennett and C. W. Ely; Soil Survey of Scott County, Indiana, by A. W. Mangum and N. P. Neill; Soil Survey of the Boonville Area, Indiana, by A. W. Mangum and N. P. Neill; Soil Survey of the Superior Area, Wisconsin-Minnesota, by T. A. Caine and W. S. Lyman; Soil Survey of Tama County, Iowa, by C. W. Ely, G. N. Coffey, and A. M. Griffen; Soil Survey of Saline County, Missouri, by M. E. Carr and H. L. Belden; Soil Survey of the O'Fallon Area, Missouri-Illinois, by E. O. Fippin and J. A. Drake; Soil Survey of Webster County, Missouri, by J. A. Drake and A. T. Strahorn; Soil Survey of the Kearney Area, Nebraska, by J. O. Martin and A. T. Sweet; Soil Survey of Allen County, Kansas, by J. A. Drake and W. E. Tharp; Soil Survey of the Garden City Area, Kansas, by J. L. Burgess and G. N. Coffey; Soil Survey of the Cando Area, North Dakota, by E. O. Fippin and J. L. Burgess; Soil Survey of the Greeley Area, Colorado, by J. G. Holmes and N. P. Neill; Soil Survey of the Bear River Area, Utah, by C. A. Jensen and A. T. Strahorn; Soil Survey of the Yuma Area, Arizona-California, by J. G. Holmes et al.; Soil Survey of the Sacramento Area, California, by M. H. Lapham, A. S. Root, and W. W. Mackie; Soil Survey of the Bakersfield Area, California, by M. H. Lapham and C. A. Jensen; Soil Survey of the San Bernardino Valley, California, by J. G. Holmes et al.

During the calendar year 1904, 28,444 square miles, or 18,204,160 acres, were surveyed and mapped on a scale of 1 in. to the mile. Prior to that year the total area surveyed and mapped was 60,411 square miles, or 38,663,040 acres. The average cost of the work in 1904 was $2.43 per square mile. The total area surveyed and mapped up to July 1, 1905, was 99,408 square miles, or 63,621,120 acres, distributed among 43 States and Territories.

It is stated that "the surveys have been so distributed that nearly every prominent agricultural interest has been touched, and the soils of some part of every important agricultural region have been studied. Aside from the specific problems which affect individual areas, there have been developed a number of vital problems which concern wide extents of agricultural land," such as the classes of soils especially adapted to sugar beets, tobacco, early vegetables and fruits, corn, grapes, rice, apples, small grains, grasses, etc., and the reclamation of alkali lands.

"About 400 different types of soil have been encountered by the Soil Survey since the beginning of its field work in 1899. These soil types have been studied and classified with a view to ascertaining the particular crops which each type is best suited to produce. They have also been studied from the double standpoint of meeting the local needs and of placing the particular type not only in its true relationships to the area in which it occurs, but also in its proper place in the general classification of the soils of the United States. Holding these two objects in view, the study of the soils through the field work is coming to have two primary objects. The first of these, the discovery of the best crops for each soil, is known as crop adaptation. The second, or the study of the method by which each soil may be induced to grow the largest economical crop, is known as the soil fertility or the soil management problem. In addition, various local problems are encountered in nearly every area."

It is explained that the classification of soils used in this work is based mainly on texture, structure, organic matter content, and physiographic relationships. "In the classification employed by the Bureau of Soils the aim is to secure a simple, general system, which shall express those facts with regard to soils which are easily recognizable by a person possessing ordinary powers of observation and no unusual knowledge either of classifications or of soils. For this purpose the common names of soils used by the general agricultural public are adopted and defined for use in the Soil Survey reports. Owing to the fact that in different localities soils of the same texture will receive slightly different names, it has been found necessary to define rather carefully what is meant by a clay, a loam, or a sand. Thus, in regions where the heavy clay or clay loam soils predominate a somewhat sandy soil is very often considered to be a real sand, while if it were compared with the soils of a sandy locality it would be considered and would be spoken of as a rather heavy loam.

"Through the use of its standard method of mechanical analysis, which determines the amounts of the different-sized particles found in a soil, the Bureau aims to eliminate these local differences in soil naming, in order that a uniform standard, such as may be used both for scientific and practical purposes, may become common throughout the regions where surveys are made. The naming of the soils is not intended to introduce confusion, but rather to avoid the use of local designations which may mean one thing in one place and another thing in a different place."

It is stated that "in order that the vast amount of valuable information which has been secured by the experiment stations may be made of the most direct application to each farming community within the State served, it is necessary for the farmer to know not only the details of any particular experiment, but also for him to be able to judge whether his own farm contains the types of soil upon which the experiment has been carried on, and whether it lies within the same general climatic belt as the experiment station itself. If he can be assured of these two facts, it is then possible for him to derive the greatest benefit from the results of any particular experi-

ment. If he can not be assured of these facts, it remains for him to discover whether the conditions under which he is working are the same as those which are found at the experiment station.

"The Soil Survey is thus seen to serve not only a local purpose of this kind, but through its general classification of the soils of extensive regions it has frequently occurred that the results secured at a given experiment station become applicable not only within the limits of that State, but are also found to be applicable in other adjoining States, or throughout a considerable region. It thus renders the results of experiments conducted at the various experiment stations applicable throughout a wide range of territory not restricted by State lines."

The recent work of the American Soil Bureau, E. J. RUSSELL (*Jour. Agr. Sci., 1 (1905), No. 3, pp. 327-346, pl. 1, figs. 2*).—The more technical work of the Bureau of Soils of this Department, especially as related to soil fertility, soil physics studies, and alkali soils is critically reviewed and some of the practical applications of the results are pointed out.

Soil investigation and applied soil investigation or technology of soils, E. RAMANN (*Jour. Landw., 53 (1905), No. 4, pp. 371-374*).—The author argues in favor of the drawing of a clear distinction between soil investigations as an independent subject of scientific inquiry, and the technology of soils, which deals with the application of the results of soil investigations to agriculture.

The mineral constituents of the soil solution, F. K. CAMERON and J. M. BELL (*U. S. Dept. Agr., Bur. Soils Bul. 30, pp. 70, figs. 4*).—The nature and purpose of this bulletin is concisely stated by the authors as follows:

"In order to establish the views and premises that are fundamental for certain researches which the Bureau has been and is now conducting, it has been deemed advisable to bring together the more important data which the publications of other investigators furnish, together with some further experimental results obtained in the laboratories of the Bureau. The literature bearing on this subject is now very voluminous, confusing, and contradictory. It has not been deemed advisable to undertake a complete bibliography, but it is believed that sufficiently numerous citations have been made to give an accurate idea of the present status of the subject, as well as to demonstrate the points which it is sought to establish in the text."

The bulletin reviews the literature and discusses the general characteristics of soil; the minerals found in soils and their solubility and hydrolysis; solubility of the minerals as affected by temperature, pressure, carbon dioxid, inorganic acids, organic compounds, and vital agencies; absorption of gases and of solutions (by soil, sand, paper, carbon, silica, kaolin, etc.); chemical reactions at surfaces; and flocculation.

Studies of the properties of and the phenomena presented by the soil solution are considered of fundamental importance, because previous studies of the Bureau have led to the conclusion that "the growing plant obtains its mineral nutrients directly from the aqueous solution formed by the soil moisture."

The principal points which it is sought to establish in this bulletin are that as a rule "(1) the soil contains all the common rock-forming minerals. There may be, indeed probably are, extreme cases for which this statement would not be strictly accurate, but it may be regarded as a rule holding quite rigidly for practically all arable soils. It has also been shown that the weight of available evidence justifies the further generalization that—

"(2) Some, at least, of each mineral species in the soil is presenting surfaces of the mineral as such to the solvent action of the soil water. This being the case it follows that—

"(3) The minerals of the soil will continue to dissolve. On dissolving the minerals carrying the stronger basic or acidic constituents will be more or less completely hydrolized, and generally the stronger hydrolization product will remain in solution and the weaker one will be more or less completely precipitated. It is thus that the

principal mineral plant-food constituents are brought into solution and made available to the plant. What concentration the soil moisture actually possesses has been determined with what may be regarded as approximate accuracy. Two methods have been devised for extracting the free solution actually existing in a soil, and analyses of a number of such extracts obtained from several types of soil of widely different origin and composition have yielded an average for potassium (K) of 27.3 parts and for phosphoric acid (PO_4) 8.5 parts per million of solution.

"The approximate uniformity of the individual results make it appear improbable that further accumulation of data would change these average figures materially. . . . Since practically all soils contain the same minerals and essentially the same processes are taking place in all of them it would follow that about the same solution should be expected in all soils, except in so far as changes were introduced by differences in absorptive powers of the solids, rates of movement of water, etc. Examinations of a large number of soils, many of which have been already published, established empirically that these considerations are justified. . . .

"(4) The concentration of the soil solution, with respect to the principal mineral plant-food nutrients, is sufficient for the growth and development of crops. And, further, the magnitude of the concentrations is the same for practically all soils."

A review of studies of the effect of surfaces in modifying not only in intensity but even in kind the reactions taking place in solutions in contact with them and of the nature and effect of the organic matter of the soil leads to the general conclusion that "the development of a modern soil chemistry is dependent upon a study of the chemical changes induced by surface contact, and upon a study of the proportions of the water soluble organic as well as inorganic matter of the soil."

A comparison of the results obtained by the method of cultures in paraffined wire pots with field results on the same soil, H. J. WHEELER, B. E. BROWN, and J. C. HOGENSON (*Rhode Island Sta. Bul. 109, pp. 13–44, pls. 5*).—This is an account of a series of experiments made in cooperation with the Bureau of Soils of this Department to test the value of the paraffined wire pot method of testing the fertility of soils devised by the Bureau (E. S. R., 16, p. 650; 17, p. 227). Seventeen series of experiments with soils from plats which have been under experiment at the station for several years past and from a farm on the Kingston Plain are reported. These include tests of various combinations of fertilizers, barnyard manure, green manure, lime, etc., on corn, wheat, crimson clover, alfalfa, and lettuce, the effect of continuous planting on the same pots with and without renewal of the manures, fertilizers, etc., being studied.

The results are thus summarized:

"Tests by the method of paraffined wire pots of a soil which, under the existing field conditions was so poor as to produce Indian corn only 5½ in. high during the entire season, revealed manurial requirements in accord with those shown by plant tests in another part of the same field. This was true both before and after liming. Marked benefits from liming and from the use of stable manures, similar to those observed in the field, were also obtained.

"It was shown by this method that 'denitrification,' or a destruction of nitrates, very likely resulted where the stable manure and nitrates were used together. There is no evidence to show that this denitrification was necessarily any more pronounced than it would have been in ordinary pots.

"The use of all three mineral manures, in addition to lime, also depressed the yield. This effect was apparently lessened by the presence of horse manure. Upon the third replanting this ill effect disappeared. It seems probable that upon a similar soil, if limed, the quantities of the manurial substances should be reduced in making such tests.

"Benefit from adding green manures was shown in the pots, as is also the case in the field.

"Tests of like amounts of coarse and fine horse manure show, by the pot method, poorer results with the fine material. This was probably due to the fact that the finer manure was more intimately mixed with the soil, thus causing a more even distribution of material which could furnish food for the organisms which destroy nitrates. Occasional aeration seemed in this case to have been beneficial, but in another instance it failed to lessen the apparent destruction of nitrates.

"The benefit, shown by the method of paraffined pots as a result of introducing hay, straw, and green parts of plants into the soil, was striking. The materials are arranged below in the order of the benefit observed when used with lime, the most beneficial being at the top: Cowpea vines, Indian corn plants, rye straw, clover plants, sumac stems and leaves, timothy hay.

"In a trial of different phosphates for purposes of comparison with field results, the data obtained with the paraffined pots point in most particulars in the same direction as those obtained in the field. The effect of lime in increasing the efficiency of roasted 'Redondite' (iron and aluminum phosphate), as shown by the pots, was also in agreement with field trials.

"Comparisons of both the after effect and the immediate effect of sodium and potassium salts, though showing agreement with field results in the main essentials; differed considerably. This was doubtless due in part to unequal drying out of the soil in the first instance, before the tests were made, and to the fact that the variety of plant was not the same that was used in the field.

"Pot tests of the soil where nitrates had been used for grass in different amounts gave results essentially as were to be expected from the field experiments.

"The effect of fresh horse manure in depressing the yield and transpiration is in accord with other observations, and it may have been due to a destruction of nitrates. A similar effect of dried horse manure was also observed.

"The influence of liming both in connection with nitrate of soda and suphate of ammonia was shown by the pot tests with several varieties of plants, to be in good agreement with field tests.

"A test of an unproductive soil at West Kingston, which was of similar origin to that upon the experiment station farm, revealed the same requirements both before and after liming as the station soil. Liming was also helpful.

"In general, the tests by the method of the paraffined wire pots show good agreement with field observations of a whole season's duration."

Unproductive soils, T. Biéler-Chatelan (*Chron. Agr. Vaud, 18 (1905), Nos. 22, pp. 531–535; 23, pp. 558–562*).—This article discusses soils rendered unproductive by defective drainage and bad physical condition due especially to improper and exhaustive methods of culture, and describes various methods of improving such soils.

Some changes in the soil under the influence of the activity of earthworms, A. Murinov (*Mater. Izuchen. Russ. Pochv., 1905, No. 16; abs. in Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 4, pp. 460, 461*).—Alternate layers of different kinds of soil were placed in zinc boxes with one glass side, earthworms were added, the soil kept in a proper state of moisture, and the changes which the soil underwent determined by analyses at the beginning and end of the experiments, which lasted one year. A check series of boxes was treated in the same manner except that earthworms were not added.

The results show that in the soils to which the earthworms were added the phosphoric acid soluble in 10 per cent hydrochloric acid increased in all cases. The lime content, which at the beginning was greatest in the surface soils, was found at the end of the experiments to gradually increase from the surface toward the subsoil. The nitrogen was more uniformly distributed throughout the soil at the end of the experiment than at the beginning.—P. FIREMAN.

The influence of a constant weak electric current on the solubility of the nitrogen and the phosphoric acid of the soil, M. YEGOROV (*Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 3, pp. 315–324*).—Experiments are reported in which a 100 voltage current varying from 0.002 to 0.23 ampere in different cases was passed through chernozem and clay soils contained in glass boxes and the effect on the solubility of the soil constituents was observed.

It was found that by this treatment the phosphoric acid soluble in citric acid was increased almost 100 per cent. The nitrate nitrogen was decreased in about the same proportion. The ammonia nitrogen, however, was increased 3 to 5 times, so that there was a considerable average increase in total soluble nitrogen, this increase evidently taking place at the expense of the insoluble organic compounds.—P. FIREMAN.

Hygroscopicity, heat evolved on moistening (Benetzungswärme), and mechanical analysis of soils, A. MITSCHERLICH (*Fühling's Landw. Ztg., 54 (1905), No. 20, pp. 673–675*).—The information contained in this article is condensed from the author's Treatise on Soils for Farmers and Foresters, published by Paul Parey, Berlin, 1905. The terms used are defined, and their relations to each other and to plant growth are briefly discussed.

It is stated that hygroscopic moisture and the heat evolved on moistening soils are of no importance from the standpoint of plant growth. Wollny's classification of soil particles is given and the comparative value of mechanical analysis, hygroscopicity and heat evolved on moistening as means of judging of the character of soils is discussed The author is of the opinion that mechanical analysis may be replaced for this purpose with advantage by the determination of the heat evolved on moistening, or preferably by determination of hygroscopicity.

The soil and the subsoil of the Veliko-Anadolsk forest as one of the causes of the decay of forest plantations, N. N. STEPANOV (*Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 3, pp. 257–299*).—The investigations here reported were made on an artificial forest plantation in the steppes region of southern Russia on lands which were formerly treeless and which have soils rich in soluble constituents (alkali). Studies of the soil and subsoil were made in places where trees were growing vigorously and in places where the trees had failed to grow.

The results show quite clearly that the failure of the trees to grow was due to excess of soluble salts (especially sodium carbonate) in the upper layers of the soil. The formation of calcareous hardpan in the subsoil had also in some cases brought about conditions unfavorable to tree growth. The lack of uniformity in tree growth on these soils is said to be due to irregularity in concentration of the soluble salts in the surface soil, varying with the topography of the land and the character of the season. The occurrence of gypsum in the soils at short distances from the surface indicates that they have not been sufficiently leached for the successful growth of trees, although gypsum itself is not an injurious salt and tends to improve the mechanical and moisture conditions of the soil.

In conclusion the author urges the importance of carefully examining such soils before forest planting is attempted, as well as the use of seeds produced on the soils of species which are known to be resistant to alkali.—P. FIREMAN.

Does the northern forest dry the soil? D. M. KRAVCHINSKI (*Lyesoprom. Vyestnik, 1905, No. 1; abs. in Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 4, p. 511*).—Comparative determinations of moisture in forest soil and in adjoining pasture soil are reported, which show that the forest soil was but slightly drier than the pasture soil.—P. FIREMAN.

On the origin of moors, C. A. WEBER (*Ztschr. Angew. Chem., 18 (1905), No. 42, pp. 1649–1654*).—A discussion of the geological and botanical factors involved in the formation of upland and lowland moors, with descriptions of the characteristics of some typical North German moors.

Calcium carbonate in some soils of Valpantena (Verona), R. DE POLO (*Staz. Sper. Agr. Ital., 38 (1905), Nos. 7–8, pp. 622–628*).

Contribution to the question of volatilization of ammonium salts in soils, H. WANGNICK (*Fühling's Landw. Ztg., 53 (1904), No. 18, pp. 695–699; abs. in Centbl. Agr. Chem., 34 (1905), No. 10, p. 714*).—Experiments on loam and sandy soils containing different amounts of calcium carbonate show the loss of considerable amounts of ammonia, varying with the proportion of lime, when ammonium salts are added to such soils. The losses observed, however, were smaller (not over 20 per cent in any case) than those reported by Wagner as having been obtained by Hals (E. S. R., 15, p. 234).

Soils and fertilizers, H. SNYDER (*Easton, Pa.: The Chemical Pub. Co., 1905, 2. ed., pp. X + 294, pl. 1, figs. 40*).—This is a second edition of this work, the first being published in 1899 under the title The Chemistry of Soils and Fertilizers (E. S. R., 11, p. 418).

"In the revision of the text the subject-matter has been entirely rewritten, new material has been added, and the laboratory practice has been made a more prominent feature. These additions have changed the scope of the book to such an extent as to necessitate a change of name. The work as now presented includes all of the topics and laboratory practice relating to soils as outlined by the committee on methods of teaching agriculture, appointed by the Association of Agricultural Colleges and Experiment Stations."

The book gives in condensed form the principles underlying the conservation of soil fertility and the economic use of manures. A bibliography of 95 references is appended.

Fertilizer inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 120, pp. 153–168*).—This bulletin contains the analyses of 253 samples collected by the station of the brands of fertilizers licensed in 1905.

The results of inspection show that as competition becomes closer and the processes of manufacture somewhat more trustworthy the fertilizers tend to more closely approach the minimum guaranty, and it rarely happens at present that fertilizers carry much above the minimum guaranteed percentages of nitrogen and potash, the more costly constituents of a fertilizer. In fact the results in 1905 show that over 80 per cent of the samples collected were below the guaranty in at least one constituent.

Analyses of commercial fertilizers, M. B. HARDIN (*South Carolina Sta. Bul. 115, pp. 30*).—This bulletin contains analyses of 522 samples of fertilizers collected during the season of 1904–5. "These analyses were published in 15 weekly bulletins issued and distributed during the months of February, March, April, and May." Eighty-four samples of cotton-seed meal, previously reported in Bulletin 105 of the station, are also included, and notes on valuation and explanations of terms used in fertilizer analyses are given.

Commercial fertilizers, H. J. WHEELER ET AL. (*Rhode Island Sta. Bul. 110, pp. 47–60*).—"This bulletin is supplementary to Bulletin No. 108, and the two contain the analyses of such commercial fertilizers as have been found on sale in Rhode Island during the year 1905."

The utilization of atmospheric nitrogen, O. N. WITT (*Chem. Ztg., 29 (1905), No. 98, pp. 1261–1264; abs. in Mark Lane Express, 93 (1905), No. 3873, Fert. and Feed., p. III*).—This article reviews the various attempts which have been made from the time of Cavendish to prepare nitrogen compounds from the free nitrogen of the air, including the more recent attempts of Bradley and Lovejoy of the Atmospheric Products Company, of Niagara Falls, and Frank's calcium cyanamid (lime nitrogen) process.

It is claimed that the former has proved too costly to be a commercial success. The commercial success of the latter depends upon the possibility of securing cheaper

methods of producing electrical energy and of freeing the nitrogen of the air from its associated constituents. The most promising results with the Frank process from a commercial standpoint have apparently been obtained in Italy, where cheap and abundant water power has been utilized in the generation of electrical energy.

The most successful electrical method which has yet been suggested, judging by the results reported, is that of K. Birkeland and S. Eyde, of Christiania, Norway. The inventors of this process, for which patents have been taken out in this country as well as in Europe, claim that it has not been possible up to the time of their discoveries to utilize electric energy in a single powerful arc for the production of nitric compounds from the atmosphere in an economical manner.

As stated in the United States patents, their invention is based upon the fact that electrical discharges between electrodes placed within a magnetic field may be dispersed by the action of the magnets, and that "an electric arc of high or low tension may be dilated or spread into a large permanent flame having the shape of a sheet or a disk of a volume several hundred times as large as a regular or primary arc of the same energy when the electrodes are placed in a suitable manner in a powerful magnetic field—for instance, between the poles of a magnet and transverse to the flux of said field."

In this way it is possible "to transform a great part of the electrical energy into heat capable of being absorbed by certain gases, as chemical energy under conditions which are attended by valuable chemical reactions. This is due to the fact that the efficiency of a flame in endothermic chemical processes is a function of the ratio between the volume and the temperature of the flame. [It is claimed that by this process it is possible] to have furnaces at continuous work with several hundred kilowatts at each flame, the heat being economically utilized, a result which was not heretofore possible unless the energy employed for each arc was only very small."

It is reported that in works which have been built at Notodden, Norway, to utilize water power from large falls in that vacinity 1,500 kg. per day of water-free nitric acid are now being made. The final product is in form of calcium nitrate, the fertilizing value of which is being studied by a number of investigators (E. S. R., 17, p. 449).

Nitric acid and nitrates from the nitrogen of the air (*Ztschr. Angew. Chem., 19 (1906), No. 1, pp. 37, 38*).—This article deals with the Birkeland and Eyde process for the preparation of nitrogen compounds from the nitrogen of the air, and describes particularly the progress that has been made in utilizing for this purpose the abundant power furnished by waterfalls in southern Norway.

It reports that the success of small experimental works has been such that a number of larger plants are now being established at various places. The general principles upon which better methods of utilizing electric power have been based in this process are stated in the preceding abstract. It is stated that in this method the gases after treatment contain from 1 to 2 per cent of nitric oxid, which is absorbed partly in water and partly in milk of lime.

The solution thus obtained is concentrated and saturated with limestone and finally obtained either as crystallized calcium nitrate or by addition of an excess of lime according to Collett's process, in form of a basic fertilizer known commercially as "basic lime niter." The latter contains from 8 to 9 per cent of nitric nitrogen and about 22 per cent of lime as hydroxid and carbonate. This material has given very good results as a fertilizer in the experiments which have been made with it.

Calcium nitrate manufacture in Norway (*Engin. and Min. Jour., 81 (1906), No. 4, p. 192*).—A brief note on an experimental factory at Notodden, employing the Birkeland and Eyde process, referred to above, which has been in operation since the beginning of 1905, and on the construction of large additional works at Svälgfos, near Skien, where 30,000 horsepower will be available.

The new Norwegian industry of manufacture of "lime niter" (*Ugeskr. Landm., 51 (1905), No. 50, pp. 569, 570*).—The paper describes the method of Birkeland and Eyde for the oxidation of atmospheric nitrogen by electricity and the manufacture of calcium nitrate therefrom. The company which has been organized for the manufacture of this fertilizer will utilize the power of three Norwegian waterfalls to the extent of over 30,000 horsepower.—F. W. WOLL.

Nitrate of calcium factory for Norway, H. BORDEWICH (*Mo. Consular and Trade Rpts.* [*U. S.*], *1906, No. 304, pp. 245, 246*).—A brief account of recent progress in the establishment of factories for the manufacture of calcium nitrate by the Birkeland and Eyde process.

Utilization of the nitrogen of the air (*Chem. Ztschr., 5 (1906), No. 2, pp. 38–40*).—This is a note on a discussion by O. N. Witt of the Birkeland and Eyde method (see above).

The principle upon which the method is based is briefly explained and some of the practical results already obtained in Norway are given. It is stated that an experimental plant, which has been in operation for a year or more, has utilized water power in the production of electrical energy at a cost of 12 marks (about $3) per horsepower yearly. It has produced from 500 to 600 kg. (1,100 to 1,320 lbs.) of water-free nitric acid per kilowatt year. The daily output has been 1,500 kg. (3,300 lbs.) of water-free nitric acid.

The production of nitric acid from the air, M. BODENSTEIN (*Ztschr. Angew. Chem., 19 (1906), No. 1, pp. 14–21*).—A review of recent progress in development of commercial processes of manufacturing nitrogen compounds from the air.

Nitric acid from atmospheric nitrogen, F. WINTELER (*Chem. Ztg., 29 (1905), No. 99, pp. 1278, 1279*).—This is a review of J. Brode's book on the oxidation of nitrogen in the high-tension flame, which gives a bibliography of the subject beginning with the work of Cavendish and Achard in 1784, Priestley in 1788, and L. Odier published in 1798, who observed the oxidation of the nitrogen of the air at high temperature or by means of electrical discharges.

The utilization of the nitrogen of the air, A. NEUBURGER (*Ztschr. Angew. Chem., 18 (1905), Nos. 45, pp. 1761–1766; 46, pp. 1810–1814; 47, pp. 1843–1852*).—This article deals with 4 methods of utilizing the nitrogen of the air as follows: (1) Preparation of nitrids, (2) production of ammonia and ammonium compounds, (3) formation of cyan compounds and their derivatives, and (4) the production of oxids of nitrogen, nitrous and nitric acids.

As a result of his review the author concludes that recent progress in the development of methods of utilizing the nitrogen of the air has been such that we can view without alarm the exhaustion of the Chilean deposits of nitrates. The large amount of energy, especially electrical energy, required is the greatest present drawback to the commercial success of processes of making nitrates from the nitrogen of the air, but great progress has been made in this respect in recent years and there is reason to expect that still greater progress will be made along this line in the near future.

On the utilization of the nitrogen of the air for agricultural purposes with special reference to lime nitrogen and its fertilizing value, H. IMMENDORFF and O. THIELEBEIN (*Fühling's Landw. Ztg., 54 (1905), No. 23, pp. 787–795*).—The authors report pot experiments with oats and mustard, which gave results confirming in general the conclusions of Frank (E. S. R., 16, p. 759) regarding the fertilizing value of lime nitrogen on different kinds of soils and the best methods of using this material as a fertilizer, i. e., it is not suited to acid humus soils or light sandy soil of acid reaction; it gives good results when applied 8 to 14 days before seeding at rates of 150 to 300 kg., equal to 30 to 50 kg. of nitrogen, per hectare, and immediately worked in, on soil well supplied with lime and regularly manured with barnyard manure; and it is in no case to be used as a top-dressing.

The fixation of nitrogen and electrochemistry, P. A. GUYE (*Rev. Gén. Sci., 17 (1906), No. 1, pp. 28–34*).—This article reviews the various methods which have been proposed for the fixation of nitrogen by electrical means, including the lime nitrogen method of Frank and the direct electrical methods, such as those of Bradley and Lovejoy, Muthmann and Hofer, Nernst, von Lepel, and Birkeland and Eyde. A study is given of the phenomena of the electric arc in air and of the conditions which affect its efficiency, especially the question of temperature.

Agriculture and the nitrogen supply, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 11 (1906), No. 6, pp. 165, 166*).—The importance of nitrogen in plant production, the sources of supply of this element, and the possibility of drawing on the air for future supplies are briefly discussed.

The nitrogen balance of soils (*Deut. Land v. Presse, 32 (1905), No. 97, p. 807*).—The possibility of maintaining the nitrogen balance in soils exhausted by heavy cropping by drawing on the nitrogen supply of the air is briefly discussed.

Note on the fate of calcium cyanamid in the soil, S. F. ASHBY (*Jour. Agr. Sci., 1 (1905), No. 3, pp. 358–360*).—The experiments here reported were similar to those reported by F. Löhnis (E. S. R., 17, p. 345), in which it was shown that soil bacteria, especially *Bacterium kirchneri* and *B. lipsiense*, are active agents in rendering calcium cyanamid assimilable for crops and that the reaction is not a purely chemical one as has been generally supposed.

The author's experiments were made in nutrient solutions, some of which were inoculated with extract from a fertile soil, others partly sterilized, and still others treated with corrosive sublimate. In the inoculated soils as much as 80 per cent of the cyanamid nitrogen was converted into ammonia; in those which were partly sterilized very small amounts of ammonia were formed; and in those treated with corrosive sublimate practically none was formed.

The conclusion is therefore drawn "that the formation of ammonia from cyanamid in the soil can be due in only a very minor degree to a purely chemical process." The lime nitrogen used in these experiments contained 20.3 per cent nitrogen, equal to 58 per cent of pure calcium cyanamid. "By precipitating all the lime with ammonium oxalate, evaporating the filtrate to dryness, extracting with a little strong alcohol and allowing the latter to evaporate at the ordinary temperature, to obtain yellow crystalline plates which yielded on analysis 62.70 per cent nitrogen and agreed with the description given for dicyandiamid (Beilstein, *Organische Chemie*) which contains when quite pure 66.60 per cent nitrogen. A solution of calcium cyanamid after long standing goes over into dicyandiamid which yields no ammonia by distillation with magnesia."

Calcium cyanamid (lime nitrogen), L. GRANDEAU (*Jour. Agr. Prat., n. ser., 10 (1905), No. 52, pp. 808, 809*).—A brief general account of the preparation, properties, and use of this material as a fertilizer.

Experiments with lime nitrogen (*Deut. Landw. Presse, 32 (1905), No. 92, pp. 770, 771*).—The process of preparing this substance is briefly described, the changes which it undergoes in the soil (including those due to the action of micro-organisms) are explained, and plat experiments with oats are reported.

When applied immediately before seeding, germination and growth were seriously interfered with; if applied 1 week before seeding, growth was normal. The period of growth was shortened and the protein content increased with increase of length of time the lime nitrogen was applied before seeding up to 5 weeks.

Experiments with lime nitrogen, VON SEELHORST and A. MÜTHER (*Jour. Landw., 53 (1905), No. 4, pp. 329–356; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 519, II, p. 46*).—A series of pot experiments with oats on sand, loamy sand, and loam soils to determine the best time and manner of applying this material as a fertilizer is reported. The results show that the lime nitrogen gives good results on all

moderately fine-grained soils when carefully incorporated with the soil about 8 days before the planting of the crop.

Comparative tests of the fertilizing value of nitrate of soda, sulphate of ammonia, and calcium cyanamid (lime nitrogen), L. GRANDEAU (*Jour. Agr. Prat., n. ser., 11 (1906), No. 1, pp. 8–10*).—The results of plat experiments carried out during 1904 and 1905 with these 3 substances as fertilizers for potatoes and barley are briefly reported.

The three fertilizers were used in amounts furnishing 45 kg. of nitrogen per hectare (40.08 lbs. per acre) in connection with a basal fertilizer supplying phosphoric acid and potash. In the experiments with potatoes in 1904 the relative effectiveness of the 3 fertilizers was nitrate 100, sulphate 96.5, lime nitrogen 93.4; in 1905 the relative effectiveness was nitrate 100, lime nitrogen 101.83, sulphate 95.36.

In experiments with barley in 1905 the lime nitrogen gave results somewhat better than those obtained with sulphate of ammonia, both being considerably inferior to nitrate of soda.

In connection with these experiments observations were also made upon the influence of other fertilizers supplying phosphoric acid and potash on the effectiveness of nitrate of soda. It was shown that the absence of fertilizers supplying phosphoric acid and potash greatly reduced the efficiency of the nitrate of soda. It was also shown that the nitrate of soda was almost entirely lost if its application was delayed until after the heading of cereals.

Contribution to the knowledge of the life conditions of nitrogen-collecting bacteria, H. FISCHER (*Jour. Landw., 53 (1905), No. 3, pp. 289–297*).—A continuation of previous experiments (E. S. R., 17, p. 120) is reported, showing that the activity of the organisms which fix nitrogen in the soil is greatly influenced by the character of the latter, particularly its lime content and physical condition, and suggesting that it may be possible to so modify these conditions in practice as to promote the activity of the desirable organisms and retard the development of the undesirable.

Inoculation of legumes, K. F. KELLERMAN and T. R. ROBINSON (*U. S. Dept. Agr., Farmers' Bul. 240, pp. 7*).—In this bulletin special attention is called to an improved method of distributing pure cultures of root-tubercle bacteria in nitrogen-free nutrient solution in hermetically sealed tubes, and detailed directions are given for using these cultures.

AGRICULTURAL BOTANY.

Experiments with plants, W. J. V. OSTERHOUT (*New York: The Macmillan Co., 1905, pp. XIX + 492, figs. 253*).—This book, which is one of the recent contributions to modern methods of investigation, is based upon the idea that principles involved in experiments are of prime importance, and the work is so arranged that whether used by the teacher or pupil it brings out the underlying principles of biology rather than quantitative results.

While applicable for use in the higher schools and colleges, yet it is so written and the choice of material and apparatus so simplified that it could be used in secondary schools. The author has shown how to make use of the most commonplace materials as apparatus for the demonstration of experiments showing the properties and functions of plant organs. Chapters are devoted to the various phenomena of plant life, and the work concludes with a discussion of plant breeding and the principles underlying it.

The proteases of plants, III, S. H. VINES (*Ann. Bot., 19 (1905), No. 74, pp. 171–187*).—In previous papers the author has shown the wide distribution of proteases in plants, some of which act upon the fibrin or albumin, while others attack simpler forms of proteids, as albumoses and peptones, affecting their proteolysis. To this last class of enzyms the name ereptase or erepsin is given.

Erepsin is found more widely distributed in plants than the fibrin-digesting proteases. In another publication (E. S. R., 17, p. 542) the author concluded from his studies of papain that it contained both erepsin and a fibrin-digesting enzym similar to pepsin. In the present paper the author reports having found by the same methods of study these two proteases in the juice of the pineapple, in yeast, mushrooms, malt, hyacinth bulbs, and in the liquor found in the pitchers of Nepenthes.

In summarizing the results of the investigations the author says that peptolysis appears to take place within a range extending from distinct alkalinity to a degree of acidity quite beyond that occurring in nature. On the other hand, fibrin-digestion is much less uniform, showing wide and striking differences, yeast, mushroom, malt, and Nepenthes being limited to acid reactions, while fibrin-digestion took place in alkaline reactions with papain, pineapple, and hyacinth bulbs.

All the plants examined contained ereptase. In some of these it was found to be associated with a greater or less proportion of a peptase, but in no plant was a peptase found to exist unassociated with ereptase.

The nitrogen nutrition of chlorophyll-bearing plants, O. Treboux (*Ber. Deut. Bot. Gesell., 22 (1904), No. 10, pp. 570–572; abs. in Jour. Chem. Soc. [London], 88 (1905), No. 510, II, p. 276*).—A preliminary report is made of investigations on the availability of various forms of nitrogen for plants. The studies included nearly all groups of chlorophyll-bearing plants and comparisons were made with some fungi.

The summary account given shows that nitrogen as nitrites is generally available when in alkaline solutions, but poisonous in acid solutions. The poisonous action depends upon the degree of concentration of the solutions, and for the nitrites it is a little lower than for the ammonium salts. In comparing nitrates and nitrites it was found that they possessed practically the same efficiency, although in a few instances nitrates proved of greater nutritive value than nitrites. Ammonium salts were found to be still more available than either nitrates or nitrites.

In comparing the organic compounds, amins and amids were studied, and for the lower groups of plants they were found to be about equally valuable. For the higher chlorophyll-bearing plants the amids are said to be less assimilable. The ammonium salts of corresponding organic acids are more assimilable than the amin acids. The author believes that asparagin and similar compounds are split up by enzyms and the ammonia liberated, and further that they are not directly used by the plant in forming proteids. It is claimed that ammonium salts are most suited to the nitrogen nutrition of chlorophyll-bearing plants, and that the intervention of nitrite and nitrate bacteria is not always necessary.

Studies of endotrophic mycorrhiza, I. Galland (*Rev. Gén. Bot., 17 (1905), Nos. 193, pp. 5–48; 194, pp. 66–85; 195, pp. 123–136; 197, pp. 223–239; 199, pp. 313–325; 202, pp. 423–433; 203, pp. 479–500, pls. 4, figs. 6*).—The author has made anatomical and biological studies of many forms of endophytic growth, some of which are but little known. His investigations have shown the possibility of grouping the mycorrhiza into 4 series.

In the first series, which is represented by *Arum maculatum*, the mycelium after penetrating the cortex of the root develops among the cells, terminating in haustoria, which limit further growth. In the second series the mycelium penetrates the cells and the haustoria are developed latterly, their growth being indefinite. This type is represented by *Paris quadrifolia*. In the third series, typified by the Hepaticæ, the mycelium spreads over the soil and lower surface of the thallus. It enters the host through the rhizoids and develops within the plant cells, where the haustoria are transferred into spongioles. The growth of the mycelium is indeterminate. The fourth series is found among the orchids, where the mycelium is always intracellular and indefinite in growth and assumes a closely knotted development.

Aside from these distinguishing characters, all kinds of mycorrhiza show a uniformity of constitution and cytological structure of the mycelium, and the presence

of certain special organs which are concerned either with the temporary storage of reserve material or as absorptive organs. The author holds that mycorrhiza exist as sort of internal saprophytes, taking through their haustoria some of the elaborated material in the cortical cells of the host plant, and in turn the host plant makes use of the mycorrhiza through the digestion and absorption of the haustoria and other organs. Instead of a harmonious symbiosis, the author claims that the relationship is one of feeble antagonism between the fungus and its host. A bibliography of literature is included.

Heliotropism indirectly caused by radium, H. MOLISCH (*Ber. Deut. Bot. Gesell., 23 (1905), No. 1, pp. 2–8, fig. 1; abs. in Jour. Chem. Soc. [London], 88 (1905), No. 512, II, p. 412*).—Experiments with radium preparations alone failed to show any heliotropic motion in seedlings of vetch, lentil, and sunflower, or in *Phycomyces nitens*, but when mixed with zinc blende a very active movement was induced. The effect is attributed not to the emanations from radium, but to the phosphorescence induced in the zinc blende. Laboratory experiments were highly successful, but in a forcing house the experiments failed, owing, it is thought, to the presence of traces of illuminating gas and other impurities in the air.

Hemicellulose as a reserve material in forest trees, H. C. SCHELLENBERG (*Ber. Deut. Bot. Gesell., 23 (1905), No. 1, pp. 36–45*).—A summary is given of the observations of the author and others on the occurrence of hemicellulose as a reserve material in forest trees. This form of cellulose is said to be deposited toward the end of the growing season, and may be used by the tree any time before becoming lignified.

Wild medicinal plants of the United States, ALICE HENKEL (*U. S. Dept. Agr., Bur. Plant Indus. Bul 89, pp. 76*).—A compiled list is given of the drug plants of this country, using as a basis the catalogues of dealers in crude drugs and the standard works on systematic botany.

Only such wild medicinal plants as have commercial value are considered. Both official and nonofficial drugs are included in the list, the information being given under the accepted botanical name of the plant. Brief notes are given indicating the more important features of habit, growth, distribution, parts of the plant used, and the official status of the product, etc.

International catalogue of scientific literature. M—Botany (*Internat. Cat. Sci. Lit., 3 (1905), pp. VIII+909*).—This is the third annual issue of the catalogue of scientific papers published under the auspices of the International Council by the Royal Society of London. The plan is the same as that previously announced (E. S. R., 14, p. 637). The literature indexed is mainly that of 1903, the material employed having been received between March, 1904, and February, 1905. The author catalogue embraces about 5,000 titles.

FIELD CROPS.

The thorough tillage system for the plains of Colorado, W. H. OLIN (*Colorado Sta. Bul. 103, pp. 32, figs. 7*).—The methods of plowing, harrowing, subsurface packing, and summer fallowing in connection with dry farming are described; the importance of seed selection for semiarid conditions pointed out; and directions for the culture of different crops on semiarid lands are given. The annual rainfall in Colorado is recorded and the experience in dry farming in other States is noted.

In a limited cooperative experiment a field with a light seeding of wheat had as good a stand as a field seeded at nearly twice the rate, due to the difference in the size of the kernels. The rate of seeding different grain and forage crops in dry farming is given in a table.

Of the spring wheat varieties Kubanka durum has appeared best adapted to the dry land areas of Colorado, and among the winter wheats Turkey Red has given the

most satisfactory yields. *Bromus inermis* has proved to be one of the best drought-resistant grasses brought into the State. *Agropyrum occidentale* is considered one of the hardiest and best native hay grasses.

It is stated that when the straw necessary to produce a bushel of wheat is estimated at 90 lbs. the water required in Colorado to produce 1 bu. of grain amounts to 56.25 tons. It is pointed out that more moisture is required to mature crops under semi-arid than under humid conditions. Ranking from lowest to highest in the amount of water required for maturity, the common field crops are given in the following order: Corn, potatoes, wheat, barley, field peas, oats, alfalfa, and red clover.

Fallow culture of chernozem, S. V. SHCHOOSYEV (*Zhur. Opuitn. Agron.* (*Russ. Jour. Expt. Landw.*), *6* (*1905*), *No. 1, pp. 1-9*).—The results of fallow and rotation tests conducted at Ploti for several years are discussed.

In one system of fallowing the land was plowed in the fall or in the spring and left without a crop, while in the other an intercultural crop like mustard, buckwheat, vetches, etc., was grown after plowing and before sowing the winter grain. Under the first system fall-plowed land is known as the black fallow and the spring-plowed soil as early, medium, or late green fallow, according to the time of plowing from early in spring to the end of June. The following rotation was practiced: First year, black fallow with the plowing from 7 to 10½ in. deep; second year, winter rye or winter wheat; third year, spring wheat, oats, or barley; fourth year, root crops; fifth to eighth years, grass and leguminous crops, and ninth year, flax, millet, or wheat.

Early green fallow gave slightly lower yields than the black fallow, but is considered by the author as preferable. Perennial grasses in the rotation proved effective in the improvement of the soil. Winter wheat proved more profitable than winter rye.—P. FIREMAN.

Fertilizer demonstration work in 1904, H. SVOBODA (*Ztschr. Landw. Versuchsw. Oesterr.*, *8* (*1905*), *No. 9, pp. 834-845*).—These demonstration tests were carried on in the locality of Kärnten by 256 farmers, of whom 173, or about 68 per cent, reported results. The year before 211 had carried on this work and 137, or 65 per cent, reported the results secured.

Of the reports received the first year 42.6 per cent, and of those received the second year 50.5 per cent were used in the compilation of the average data. On meadows Thomas slag and 40 per cent potash salt were used in quantities furnishing 70 kg. of phosphoric acid and 65 kg. of potash per hectare, respectively. In the cereal and hoed crop tests the nitrate of soda used furnished 24 kg. of nitrogen; the superphosphate, 55 kg. of phosphoric acid; and the 40 per cent potash salt, 42 kg. of potash per hectare. The cost of the plant-food elements per kilogram was 34 heller for phosphoric acid in Thomas slag with 18 per cent total phosphoric acid, 43 heller for superphosphate with 18 per cent of water soluble phosphoric acid, 194 heller for nitrogen in the form of nitrate of soda, and 29.5 heller for potash in 40 per cent potash salt.

The fertilizer application on meadows more than paid for itself in the first cutting of grass, so that the second cutting and the increase of the growth the next year are regarded as clear gain. The increase in yield apparently due to the fertilizer ranged from 30 to 40 per cent. In the field crop experiments the results also proved profitable. An increase of 40 per cent in the yield of oats and of over 50 per cent in straw was obtained during the 2 years. The yield in potatoes was increased by 41 per cent the first year and by 24 per cent the second.

The influence of cultivation of moorland meadows on the yield and on the effectiveness of commercial fertilizers, E. WEIN (*Deut. Landw. Presse*, *32* (*1905*), *No. 89, p. 745*).—The results obtained by the moor culture station at Weihanstephan showed that the use of commercial fertilizers on meadows of this class without cultivation is unprofitable.

The removal of the moss from the surface by means of a harrow and the subsequent sowing of grasses and other leguminous plants aerated the surface soil and produced a good effect, but it was inadequate for the complete utilization of the commercial fertilizers applied. The best success was obtained when the original sod was plowed up, well worked, and sown to clover and grass. In this way the soil was sufficiently aerated, good forage secured the first year, and the land freed from weeds. For the first year an application of 200 kg. of potash and 150 kg. of phosphoric acid, and for the second year 120 to 150 kg. of potash and 100 kg. of phosphoric acid per hectare are recommended.

For the formation of a new sod 40 per cent potash salt is considered best, while for the maintenance of an old soil kainit may be used instead. Phosphoric acid is generally applied on these meadows in the form of Thomas slag, but superphosphates are also effective. Of the raw phosphates lime phosphate only proved satisfactory. Lime rendered the soil more friable, promoted aeration and bacterial development of the soil, and so acted indirectly in furnishing plant food. The applications of commercial fertilizers were effective in direct proportion to the cultivation given.

Report on the experimental farms in the Central Provinces for the year 1904-5, C. E. Low (*Rpt. Expt. Farms Cent. Prov. [India], 1904-5, pp. 32*).—The work for the year 1904-5 at the several experimental farms, including a cattle breeding farm and a seed farm, is reviewed.

The experimental results obtained establish the superiority of nitrate of soda as a top-dressing in connection with irrigated crops to most other forms of fertilizers. Upland Georgian cotton acclimatized on the farm during the last 10 years was distributed in several districts and gave promising results. In experiments with rice, transplanting gave by far the best results over the untransplanted crop. An awned variety of *Pennisetum typhoideum* maintained its superiority and is becoming popular among cultivators.

Selections made from *Andropogon* sorghum excelled the older strains in both yield and quality of grain. Brief notes on work with cowpeas, peanuts, and other forage crops are given.

Guide to experiments conducted at Burgoyne's (university) Farm, Impington, and at other centers in the eastern counties, T. H. MIDDLETON (*Cambridge Univ., Dept. Agr., Guide to Expts., 1905, pp. VIII+67, plan 1, dgms. 4*).—Results of cooperative experiments with different field crops are reported in tabular form with brief notes.

The Long Red mangel was apparently the leading variety on all deep fertile soils, while for general purposes on soils not suited to this variety the Globe and Tankards did best. The Yellow Globe, as shown by experiments at two centers, yielded 29.9 tons of roots containing 3.2 tons of dry matter and 1.88 tons of sugar per acre; while Long Red, with the same yield of roots, produced 3.92 tons of dry matter and 2.36 tons of sugar. The results of 3 seasons' tests at Burgoyne's (university) Farm show that Sutton Long Red produced 81 cwt. of dry matter per acre as compared with 66 cwt. for Carter Windsor Yellow Globe.

In studying the effect of fertilizers on the composition of mangels it was found that individual large roots are often richer than individual small roots. In the case of Long Red mangels, as the size increased from 2 to 3 lbs. the dry matter decreased 0.7 per cent; from 3 to 4 lbs., 0.6; from 4 to 5 lbs., 0.4; from 5 to 6 lbs., 0.3; and from 6 to 7 lbs., 0.2 per cent. In fertilizer tests with swedes the effect of omitting phosphates was marked. The use of a complete application increased the weight of the roots and decreased the percentage of sugar.

Findlay British Queen ranked first in a variety test with potatoes with an average yield of 12 tons 6 cwt. of merchantable tubers. Whole sets for seed gave better

results than tubers cut in 2 or 3 pieces, and the larger cuttings produced heavier yields than the smallar ones.

Thousand Dollar and Banner, both Canadian varieties of oats, ranked first in the average yields of grain and straw for 3 years. In a rotation test the best effect on the yields of mangels, oats, and hay was secured where $\frac{3}{4}$ cwt. of sulphate of ammonia, $1\frac{1}{4}$ cwt. of nitrate of soda, 6 cwt. of superphosphate, $1\frac{1}{2}$ cwt. of sulphate of potash, and 10 tons of barnyard manure per acre were applied to mangels.

The agathi plant (*Dept. Agr. Madras Bul. 52, pp. 21-30*).—Notes are given on the growth of this plant in connection with the cultivation of the betel vine, which is trained upon it. In addition to this, its principal use, the leaves and tops of the plant are used for forage.

Under what conditions does potash fertilization reduce the protein content of malting barley? O. Reitmair (*Ztschr. Landw. Versuchsw. Oesterr., 8 (1905), No. 10, pp. 863-944*).—This article is a review of experimental work by different investigators on potash fertilization and its relation to the protein content of barley. Many of the data discussed are tabulated and a list of 35 references consulted in the preparation of the article is given.

Basing his conclusions on the data reviewed, the author points out that soil and climatic conditions unfavorable to the production of malting barley can not be offset by applying potash. If the climate is favorable and the soil too rich, a change in the crop rotation will be more effective than potash fertilization. It is believed that weather conditions most largely control the low protein content of barley, and that if the soil contains sufficient available nitrogen none should be given in the fertilizer, or the quantity should be small. Potash applied under these conditions, especially on soils in need of the element, may reduce the protein content in connection with an increase in the yield but this does not always occur.

As chemical analyses do not indicate that a soil will be benefited by potash application, this must be determined by experimentation. A soil poor in nitrogen may be given a rather heavy application of nitrate of soda without perceptibly influencing the protein content of the grain and potash in such cases may reduce the protein in the kernel, but this depends upon whether the soil responds to potash. An increase in the nitrifying power of the soil due to frequent cultivation, especially on deep fertile soils, may for a time make the soil less suited to the production of low protein barley.

It is stated that good malting barley contains from 9 to 11 per cent of protein in the dry matter, or from 8 to 10 per cent in the air-dry grain, with 10 per cent of moisture. Deep, well-drained loess soil, uniform in the size of the soil particles and of good texture, is considered best for the production of barley low in protein. The productivity of a soil for this purpose should be more dependent upon a favorable distribution and conservation of the soil moisture than upon the plant food it contains. Good malting barley is also produced on heavier and lighter soils than the kind just described, but the production of a crop of the desired quality is less certain. During the periods before and after heading a uniform, uninterrupted, and adequate moisture supply is the most important factor in determining the quality of the product, and these conditions are most likely to obtain in a loess soil.

Owing to its rather small root system and its limited time of growth, the development of spring-sown barley goes on very rapidly before heading, and the plant under these conditions may take up large quantities of nitrogen and other plant foods. After the heads have appeared the formation of dry matter is believed to go on more rapidly than the absorption of plant food, and if the moisture supply is insufficient at this period the quantity of nitrogen taken up is too large as compared with the amount of dry matter formed, and a grain high in protein and ash is the result. In this connection the influence of climate, season, and rainfall is indicated and the value of improved varieties is discussed.

According to the author, the principal point brought out in the work reviewed is that potash fertilization reduces the protein content only when the quantity of available potash in the soil is at a minimum, and especially on the less fertile soils when a heavy application of nitrogen has been given.

Under what conditions does potash fertilization reduce the protein content of malting barley? J. STOKLASA (*Ztschr. Landw. Versuchsw. Oesterr., 8 (1905), No. 11, pp. 957-982*).—A controversial article in answer to O. Reitmair.

The importance of the stooling capacity in cereal breeding, J. SPERLING (*Fuhling's Landw. Ztg., 54 (1905), No. 12, pp. 397-400*).—Individual wheat plants, ranging in number of stems from 6 to 22, were examined. The yield per plant was found to increase quite regularly with the number of stems, being 14.40 gm. per plant in the group with 6 stems and 49.29 gm. for the plants with 22 stems.

Of the plants studied 7.92 per cent were low, 7.30 per cent medium, and 21.78 per cent high in stooling capacity. The plants with the medium number of stems were not only the most numerous, but also gave the highest average yield of grain per head. The author concludes from these results that for breeding purposes plants medium in stooling capacity should be selected.

Drilling clover seed with the nurse crop, BACHMANN (*Deut. Landw. Presse, 32 (1905), No. 98, p. 814*).—The results obtained show that germination and initial growth on the drilled plats were of greater regularity than on those sown broadcast, and that the stand of clover where broadcasted was uneven, while on the drilled plats it was regular. The soil between the drills when the clover was 4 to 5 in. high was completely covered, and Italian rye grass, which was sown with the clover, developed perfectly.

Selecting and preparing seed corn, P. G. HOLDEN (*Iowa Sta. Bul. 77, rev. ed., pp. 167-230, figs. 43*).—A revised edition of a bulletin previously noted (E. S. R., 16, p. 40) containing in addition to matter already published a report on seed corn tests made in 1905. Directions for storing seed corn and for testing each ear are also added.

Over 3,300 samples of seed corn representing every section of the State, and each sample consisting of 200 kernels taken from 100 ears of each farmer's seed, were tested. The average results of these tests show that approximately 19 per cent of the seed was entirely dead, 21 per cent low in vitality and unfit for planting, and only about 60 per cent good seed with strong, vigorous germination and giving a promise of well-developed, productive plants.

Observations on the stand were made in more than 1,000 different cornfields and it was found that in some the stand was only 40 per cent of perfection, while in others it ran as high as 95 to 96 per cent. It is estimated from these observations that on the average for the State the actual stand was about 65 per cent of a perfect stand.

In another experiment seed secured from 90 different farmers living within a radius of 10 miles from the station was compared. The experiment was repeated 3 times under identical conditions. The average yield of the 6 highest-yielding samples was at the rate of 77.5 bu. per acre, and of the 6 lowest-yielding, 35.6 bu. The yields of these 12 samples ranged from 31.5 to 80.5 bu. per acre.

The amount of water used by growing corn, R. W. CLOTHIER (*N. Dak. Farmer, 7 (1905), No. 1, pp. 5, 6*).—Three stalks of corn were grown in the open in a cylinder 18 in. in diameter and 4 ft. high, filled with soil. At the bottom of the cylinder was a reservoir shut off from the air. The soil was saturated with water and the reservoir filled.

The water used by the plants was measured by the quantity required to keep the level in the reservoir constant as corrected by the loss due to evaporation from a check cylinder. During the 24 days prior to July 12, when the plants were beginning to silk, 7 in. of rain fell and in addition 132 lbs. of water was required to keep

the level in the reservoir constant. Since the plants were 2 ft. high a daily average of 3 lbs. of water was used per stalk, which is equivalent to a rainfall of 1 in. every 7½ days.

What is an ear of corn? E. G. Montgomery (*Pop. Sci. Mo., 68 (1906), No. 1, pp. 55–62, figs. 14*).—The observations made suggest to the author that corn and teosinte may have had a common origin, the progenitor of these plants probably being a large much-branched grass, each branch being terminated by a tassel-like structure bearing hermaphrodite flowers

In the process of evolution the cluster of pistillate spikes in teosinte is considered as having developed from the lateral branches of a tassel-like structure while the corn ear developed from the central spike. It is further indicated as probable that the central tassel, as evolution progressed, produced only staminate flowers while the lateral branches produced only pistillate flowers, and that this differentiation was accompanied by a shortening of the internodes of the lateral branches until they were entirely inclosed in the leaf sheaths, as is the case with en ear of corn.

Weevil-resisting adaptations of the cotton plant, O. F. Cook (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 88, pp. 87, pls. 10*).—This bulletin contains an account of observations and experiments showing that some of the varieties of the cotton plant have definite weevil-resisting characters.

One of the first results in this line of work was the discovery of the weevil-eating kelep. It appears from these observations, however, that the usefulness of the insect is not limited to weevil destruction, but that by making a regular field culture of cotton possible in regions infested with the weevil it has contributed to the development of weevil-resisting characters in the plant. These characters are regarded as modifications in the plant for the purpose of self-protection against its insect enemies.

The general protective characters, the involucre as a protective structure, and the protection of the bolls and of the seed are discussed at some length. The extrafloral nectaries of the cotton plant are described and their functions as insect-attracting devices pointed out. A description of the behavior of the parasitized buds is also given.

Discussions on the cultural value of Kidney cotton, the nature and causes of weevil-resisting adaptations, and the improving of varieties by conscious and unconscious selection are presented. The different adaptations are classified as avoiding weevils, excluding weevils, attracting the kelep, and preventing the development of weevil larvæ. The adaptive characters of different types of cotton, including Kekchi, Rabinal, Pachon, San Lucas Sea Island, Kidney, and upland cottons, are also listed.

In an experiment conducted in Guatemala it was found that plants of Kekchi cotton cultivated on the United States system were much more robust and compact than the plants grown by the Indians in more crowded fields. Considerable variation in this cotton was observed even among plants grown from seed raised by the same Indian, and this fact is considered as giving promise of securing strains having the special characters required in the United States. On the other hand it was found that Guatemalan conditions cause variation in United States varieties. King lost most of its distinctive characters and broke up into a variety of types and in general receded in earliness. Allen, Sea Island, and Egyptian varieties became more precocious and in some instances gained in vigor and productiveness. Kekchi cotton in Texas grew large and rank but began to fruit toward the end of July, giving promise of successful seed production under the prevailing climatic conditions.

A test of Kekchi cotton was made at Lanham, Md., in 1905, and while this locality is at the northern limits of cotton cultivation, this variety produced more mature plants than any of the domestic and foreign varieties compared with it. It also remained more constant in Maryland than did King in Guatemala. When light frosts occurred in this locality about the end of September the Kekchi plants did not suffer more than the American upland varieties. Pachon cotton from western Guatemala grew from 52 to 79 in. high and produced no buds at Victoria, Tex.,

while at Lanham, Md., it grew to a height of only 30 to 40 in., and produced numerous buds. The Kekchi cotton plants in the experimental plats were characterized mainly by the long basal branches.

It was observed that the smooth Egyptian and Sea Island varieties were more susceptible to weevil injuries than the hairy upland sorts, and that the boll weevils prefer the smooth varieties while the keleps find the hairiness of the plants, such as those of the upland varieties, and especially of the Kekchi cotton, to their advantage. Kelep nests were found at the bases of only 41 per cent of United States upland and Sea Island varieties as compared with 76 per cent of the plants of the Kekchi cotton. The hairiness of the stalks assists the kelep in traveling over the plant, while to the boll weevil it is a serious hindrance.

Dimensions of floral buds and bracts of several varieties of cotton were compared and it was found that in Parker, King, and Allen the bracts very seldom attain a width of 30 mm., while in the Kekchi cotton the average width for all except the smallest buds was above 30 mm. The larger bracts permit the involucre to be more effectively closed, and thus constitute a distinct weevil-resisting adaptation.

Proliferation of internal tissues of the buds seemed more frequent in the Kekchi cotton than in any of our domestic varieties. Proliferation, or growth inside of the bud of loose watery tissue, prevents the development of the larvæ. It was found that the proportion of weevil punctures rendered ineffective by proliferation ran well above 50 per cent, and sometimes reached as high as 80 and 90 per cent. Observations on Parker cotton bolls showed that proliferation was complete in 24 hours after the injury had been inflicted.

"The weevil-resisting characters are much more highly developed in the variety of cotton cultivated by the Kekchi Indians of eastern Guatemala than in any other type yet known, and it produces also large bolls and lint of good length and quality, so that it may be of value in the United States. But even though the Kekchi cotton in its present form should prove, for any reason, not to be adapted to cultural conditions in the United States, it demonstrates at least the fact that the upland type of cotton is capable of assuming other characters which will render it far better adapted to cultivation in the presence of the boll weevil than the varieties hitherto grown in the United States."

Cotton growing in Guilford County, J. H. Bluford (*N. C. Agr. and Mech. Col. Bul. 1, pp. 12, figs. 2*).—Culture experiments with cotton were conducted on an almost entirely clay subsoil from which the soil had been removed and on which soiling crops had been grown for a few years with partial success for the purpose of adding humus.

Barnyard manure and commercial fertilizers were applied alone and in combination. The rows receiving barnyard manure and commercial fertilizers gave the largest yield at first picking and the rows treated with barnyard manure alone gave the largest percentage of the total yield at the second and third pickings. The largest average total yield was obtained from the rows treated with barnyard manure alone.

The culture of cotton in Argentina, C. D. Girola (*El cultivo del algodonero en la República Argentina. Buenos Ayres: P. Gadola, 1904, pp. 99, figs. 14*).—A general treatise on cotton culture with historical notes on the industry in South America, and particularly in Argentina; descriptions of the plant, its species, varieties, and most important hybrids; discussions on the climatic requirements of the crop; a classification of fibers; and statistics on production. The results of cultural tests with cotton in Argentina are briefly reviewed.

Report on the possibilities of cotton growing in the East Africa Protectorate for 1904, A. Linton and E. Brand (*London: Harrison & Sons, 1905, pp. 17*).—A report presented to Parliament summarizing the work done in cotton culture and briefly describing the different cotton districts. Meteorological records for the region are tabulated and general directions for growing cotton are given.

The lands suitable for cotton culture in the Protectorate are estimated at 1,340,000 acres, including 1,250,000 acres of coast lands, which are best adapted to the crop.

The specific effect of phosphoric acid on oat plants grown on black peaty sand, H. CLAUSEN (*Jour. Landw.*, *53* (*1905*), *No. 3*, *pp. 213–228*, *fig. 1*).—The results of a series of pot experiments showed that on this soil the use of phosphoric acid regularly increased the total yield and decreased the relative yield of grain.

Dryness and aeration of the soil reduced the effect on the yield of grain, while moisture and a lessened aeration so increased it that even the absolute yield of grain was largely diminished. The average data also indicate a reduction in the yield of grain when the total yield is increased by means of phosphoric acid. The application of this element seems to interfere with the translocation of material within the oat plant, and the fact that it favors the production of new shoots from the lower node after the main stem has headed is considered a good basis for this conclusion. The growth of these younger shoots is made at the expense of grain development.

It was also observed that the plants receiving phosphoric acid had bluish-red stems while the stems of those grown without an addition of this element were light yellow in color. It was shown by chemical analysis that the bluish-red plants contained much more lime but considerably less oxid of iron than the light yellow ones.

The effect of soil compression on the development of oats, C. VON SEELHORST AND KRZYMOWSKI (*Jour. Landw.*, *53* (*1905*), *No. 3*, *pp. 269–278*).—Field experiments in this line have been previously reported (E. S. R., 13, p. 541).

In the work here described plants were grown in vegetation boxes and the effect of compacting the soil was noted. Oats were sown April 14, and on May 11 the soil was compacted in one box while in the other the surface was hoed. From the results secured it is concluded that rolling reduces the tendency to lodge mainly because it retards the general development of the plant by lessening the air supply of the roots, decreasing nitrification in the soil, and reducing root growth. The reduction in the general growth of the plant is especially marked in the early vegetative period.

This soil treatment also retards heading, and it is believed that this results in a shortening of the lower internode and possibly a thickening of the stems and a strengthening of the cell walls. A top-dressing of nitrate of soda is recommended to counteract a possible reduction of the yield through rolling.

The influence of soil moisture on the development of oats at different stages of growth, C. VON SEELHORST and KRZYMOWSKI (*Jour. Landw.*, *53* (*1905*), *No. 4*, *pp. 357–370*).—Oats were grown in 24 pots, each filled with 22 kg. of soil adequately fertilized.

Sixteen kernels were sown in each pot, but the stand was later thinned to 8 plants. The pots were divided into 2 series, the first being kept dry in the beginning and watered later on, and the second being kept moist at first with no water applied during the later stages of growth. In the first series the check pots received no water and in the second they were supplied with moisture during the entire period of the test.

The results showed that when water was supplied in the first series beginning with July 1, the increase in total yield was 27.7 per cent; beginning with June 15, 48.8; June 1, 103.2; May 15, 136.3; and May 1, 178.9 per cent. The corresponding increases in the yield of grain were 21.4, 40.1, 107, 126.3, and 158.7 per cent. In the second series, in which the water supply was discontinued on these dates, the total yields based on the yield of the check test as 100 per cent, were as follows: July 1, 85.8 per cent; June 15, 67.3; June 1, 52.3; May 15, 44.3; and May 1, 41.3 per cent. The corresponding yields of grain amounted to 74.4, 62.3, 48.6, 44.8, and 40.8 per cent of the yields in the check tests.

The influence of the moisture content of the soil on the structure of the plant, and particularly the development of the panicle, is also briefly noted.

The structure of oat and barley stems and its relation to production, C. Kraus (*Centbl. Agr. Chem., 34 (1905), No. 10, pp. 665–668*).—Observations were made on plants from two different localities, as well as those grown on fertilized and unfertilized soil and in drills and broadcast.

Varietal differences in leafiness were more apparent in barley than in oats. The average total number of leaves and the number of basal leaves per plant was greater in the forms of *Hordeum distichum erectum* than in those of *H. distichum nutans.* Secondary stems of both barley and oats were less leafy than the initial stems. In both species the larger number of leaves was borne on the upper part of the stem. The percentage of basal leaves was smaller for barley than for oats, and in both crops the secondary stems were provided with a smaller number of basal leaves than the primary stems. The length and weight of the stems increased with the number of internodes.

No definite correlation was shown between the length, thickness, and weight of the different internodes and their total number. Long stems were found to be heavier than shorter stems with an equal number of joints, and the internodes were longer and thicker. A closer relation seemed to exist between length and thickness of the internodes than between thickness and weight. The long, thick, heavy stems of both oats and barley produced the longest and heaviest heads.

Cooperative variety tests with peas, 1902–1904, W. Edler (*Arb. Deut. Landw. Gesell., 1905, No. 109, pp. 102*).—Of the 6 varieties of peas grown Weende Victoria gave the best average yield, and the common small yellow field pea, which stood last in the average yield of peas, gave the highest yield of straw. Weende Victoria ranked second in straw production.

The longest vines were produced by Weende Victoria, Strube Yellow Victoria, and the common small yellow field pea, and the longest pods by Strube Yellow Victoria, Weende Victoria, and Strube Green Victoria. Strube Yellow Victoria produced the largest and heaviest peas. The varieties producing small-sized peas gave the highest weight per liter, while those producing the largest sized peas gave the lowest weight per liter. Evergreen Folger was the earliest variety tested. The Blue Green English pea showed the least tendency to lodge.

Varieties of potatoes, W. Bruce (*Edinb. and East of Scot. Col. Agr. Bul. 6, pp. 4*).—Cooperative experiments were made in 1904 for the purpose of testing new varieties of potatoes.

Of the 13 varieties grown Pink Blossom, Factor, Up-to-Date, Twentieth Century, and British Queen were most satisfactory when both quantity and quality are considered. In the different experiments the same varieties held approximately the same rank. Langworthy, which is unequaled for quality, and White Blossom ranked last in yield in every test. British Queen, Up-to-Date, and Langworthy are old varieties grown as standards for comparison.

The effect of commercial fertilizers on the quality of root crops and potatoes, M. Weibull (*K. Landtbr. Akad. Handl. och Tidskr., 44 (1905), No. 3–4, pp. 161–179*).—Experiments were conducted with sugar beets in 1901 and 1902, and with fodder beets and potatoes in 1903 and 1904.

In 1901 the highest sugar content was obtained with the use of 200 kg. per hectare of nitrate of soda alone, or from an application of 400 kg. of nitrate of soda and 300 kg. of superphosphate. The beets grown in these applications were from 3 to 4 per cent higher in purity than those which received 200 kg. of nitrate of soda and 300 kg. of superphosphate per hectare. These results were confirmed the following year, but the purity being very high in all cases was not affected in so marked a manner.

In all the tests nitrate of soda alone greatly increased the yield of sugar, but when applied with superphosphate the results were not quite so good. Superphosphate, although not uniform in its effect, showed a tendency to reduce the purity, and

where potash was given in addition the sugar content was also slightly reduced while the purity of the juice and the yield of sugar were not materially affected. These results are regarded as confirming, in general, the work of Maercker (E. S. R., 12, p. 531), and showing that as the quality of modern improved sugar beets is not appreciably influenced by the common kinds of fertilizers, including peat poudrette, sugar factories are not warranted in placing restrictions on the kinds or amounts of fertilizers used by beet growers.

In the experiments with fodder beets the largest quantities of dry matter were obtained from the heaviest applications of fertilizers in general use, while the highest percentages of dry matter were secured where no fertilizers were given. The composition of the beets showed that the character of the fertilization did not appreciably affect their food value.

The lowest yields of potatoes were secured where no fertilizers were used, medium yields on plats receiving superphosphate and potash, and the highest yields of tubers or starch on the plats treated with complete fertilizers. As in the case of fodder beets, the fertilizers applied placed the yield and quality in inverse ratio to each other.—F. W. WOLL.

Serradella and red clover in rotation, R. GUTHKE (*Deut. Landw. Presse, 32 (1905), No. 96, p. 799*).—It is reported that on the heath lands of Lüneburg serradella is not successful when following red clover, and that results are also unsatisfactory when red clover follows serradella.

Fertilizer tests with sugar beets in 1901 and 1902, S. L. FRANKFURT ET AL. (*Kiev, 1905, pp. IV + 561; rev. in Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 4, pp. 471, 472*).—Fifteen cooperative tests were made in 1902. In every instance the use of superphosphate and nitrate of soda in combination improved the yield, the increase varying from 107 to 11,077 lbs. per acre. In general a better quality was obtained, the increase in sugar content ranging from 0.1 to 1.7 per cent.

The superphosphate in most tests seemed more effective than the nitrate of soda, and a quantity furnishing 27 lbs. of phosphoric acid per acre and applied in the drill was apparently most advantageous. The quality of the beets was not unfavorably affected when nitrate of soda was applied. Small applications of nitrate of soda proved effective, and quantities not exceeding 50 lbs. per acre gave the best results. Even in quantities furnishing only 7 lbs. of phosphoric acid per acre superphosphate gave a noticeable increase in yield and in general seemed to give better results than Thomas slag.—P. FIREMAN.

The use of shelled and disinfected beet seed (*Deut. Landw. Presse, 32 (1905), No. 100, p. 831*).—The use of beet seed from which the hull of the seed boll has been removed is discussed and the advisability of disinfecting seed is pointed out. The advantages of shelled and disinfected seed are given as follows: (1) A reduction in the volume of the seed, (2) a greater regularity in seeding with a smaller quantity of seed used, (3) quicker germination, and (4) the destruction of parasites. It is stated that the use of this kind of seed is spreading.

Comparative analyses of varieties of cane, C. F. ECKART (*Hawaiian Sugar Planters' Sta., Div. Agr. and Chem. Bul. 12, pp. 20*).—The results of a chemical study of 17 varieties of cane are tabulated and discussed.

It was found that the various varieties when grown under like conditions made different demands upon the plant foods of the soil. It is pointed out that Striped Singapore contained 7.7 lbs. of nitrogen for each ton of solid matter produced as compared with only 4.2 lbs. for Demerara No. 117. For each ton of solid matter Demerara No. 74 had taken up 8.4 lbs. of phosphoric acid and Queensland No. 1 only 3.7 lbs. Demerara No. 74 also stood first in the quantity of potash with 35.1 lbs., and less with regard to lime, the quantity appropriated being only 3.9 lbs. The largest quantity of lime, 7 lbs. in each ton of solid matter, was found in Louisiana Striped. The analyses further showed that during the development of different crops the same

variety can differ materially as to the percentage of its nitrogenous and mineral constituents.

The relative development of the leaves and stalk, as shown by this work, is modified chiefly through climatic and soil conditions and it is pointed out that as the different parts of the plant may show different percentages of the various elements, a variation in the chemical composition of the same variety may occur during two different seasons. It is concluded that as physical and chemical changes in the soil are continually taking place the growth of the cane as well as its chemical composition may be modified from one season to another.

Manurial and other experiments with sugar cane, J. P. d'Albuquerque and J. R. Bovell (*Rpt. Agr. Work, Imp. Dept. Agr. West Indies, 1902–1904, pt. 1, pp. 4–47*).—A summary of the results of experiments carried on at Dodds Botanic Station and at five plantations in different typical localities of the island.

The soil at Dodds was of low fertility, being deficient in the mineral constituents of plant food. The plat receiving 20 tons of barnyard manure per acre gave a yield of 27.9 tons of cane, and the one receiving 40 tons 32.4 tons of cane. The use of phosphoric acid and potash in addition to the barnyard manure diminished the yield by 4 tons. The results indicated that from 60 to 80 lbs. of nitrogen in the form of nitrate of soda or sulphate of ammonia, and from 80 to 100 lbs. of potash applied early reduced the richness and purity of the juice, and that the combination of commercial fertilizers and barnyard manure gave canes yielding a slightly larger percentage of juice.

The soil on the Foursquare plantation contained an abundance of available phosphoric anhydrid. The average yield of plats receiving 35 tons of barnyard manure per acre was 28.7 tons of cane, and the results in general showed that on this field the use of commercial fertilizers in addition to 35 tons of barnyard manure per acre was not advisable for a plant cane crop.

The experiments at Hopewell plantation were conducted on an exceptionally rich clay soil. An application of 60 lbs. of nitrogen as sulphate of ammonia produced an increase of 3½ tons of cane, while when given with phosphoric acid and potash the increase was 5 tons and when the quantity of nitrogen was reduced to 40 lbs., 6½ tons. On another field a similar series of experiments was conducted with a ratoon crop. Here the best results were obtained where 50 lbs. of potash was given in January and 40 lbs. of nitrogen as sulphate of ammonia in June to plant canes, followed by 80 lbs. of nitrogen as nitrate of soda and sulphate of ammonia to ratoons. This soil was rich in nitrogen and phosphoric acid, and received before the canes were planted 40 tons of barnyard manure per acre.

On a series of one-acre plats the results showed that where 35 tons of barnyard manure was used the application of sulphate of ammonia in quantities of 200 to 400 lbs. gave increased yields amounting to from 1 to 7 tons of cane and that the use of superphosphate did not affect the yield, while an application of 250 lbs. of basic slag per acre gave an increase of 1½ tons of cane. Where 30 tons of barnyard manure was used per acre an application of 100 lbs. of sulphate of potash in addition to nitrogen and phosphate gave an increase of about 2½ tons.

Experiments with varieties of sugar cane, J. P. d'Albuquerque and J. R. Bovell (*Rpt. Agr. Work, Imp. Dept. Agr. West Indies, 1902–1904, pt. 2, pp. 57*).—The experiments here reported were conducted at Dodds Botanic Station and at 17 different plantations. In the black soil estates the best results as plant canes were obtained with B 1529, which gave a large yield and a rich juice. On the red soils B 208 stood first and B 1529 second. B 208 stands first in average yield for 4 years on both black and red soils. It is reported that plants and ratoons of this cane on red soils were about 12 per cent higher than those of the White Transparent variety. B 147, while giving markedly good results in 1 or 2 districts, did not appear to ratoon well on the red soils.

During the season of 1902–1904, 2,843 varieties of cane were raised from seed and planted out, making a total of 20,000 varieties raised from seed since 1898. Of these, 6,000 varieties have reached a second or third stage, and during this season a total of 5,574 varieties were still under cultivation and 653 varieties were reaped and analyzed. The principal varieties are briefly described.

The relation between stem and root development in the sugar cane plant, Z. KAMERLING (*Meded. Proefstat. Suikerriet West-Java, 1905, No. 83, pp. 17, pls. 5*).—A discussion of the subject with references to work by different investigators is given and the author's own results are reported.

It was found that in a single-bud cutting of cane the growing capacity of the bud was largely reduced when the roots were not allowed to develop; and likewise, when the growth of the bud was prevented the development of the roots was reduced. Cuttings with two buds treated in the same way gave similar results, but when the bud on one joint and the roots on the other were kept from growing, as by means of a band of plaster of Paris, the remaining uncovered bud and roots developed almost normally.

The results of this work, supplemented by those obtained in pot experiments, indicated that under normal conditions the development of the cane plant above ground is carried on with about the same degree of activity as the development of the root system.

Report of the division of agriculture and chemistry, C. F. ECKART (*Hawaiian Sugar Planters' Sta. Rpt. 1905, pp. 15–28*).—A report on the work of this division for the year ending September 30, 1905, is presented.

The field experiments with sugar cane and the work of the substations on the various islands are briefly noted. Cane was successfully grown from seed received in the form of pulverized cane tassels from Barbados, Jamaica, and Trinidad. The seed was sown December 21, February 4, and February 18. Cold weather retarded the growth of the early sown plants and a larger number of them died off than was the case in the later seedings.

A total of 812 seedlings was produced, of which 279 were planted in the field May 3 and July 18. On August 29, 46 of these young cane plants were replanted from cuttings, and on September 13, 47 more were treated in the same way. The remainder of the canes were allowed to flower during the fall to produce seed.

The value of shelled timothy seed, H. VON FEILITZEN (*Svenska Mosskulturför. Tidskr., 19 (1905), No. 1, pp. 79, 80*).—The results of pot experiments indicated that shelled timothy seed for seeding purposes has a much lower value than whole seed.—F. W. WOLL.

A study of Deli tobacco, D. J. HISSINK (*Meded. Dept. Landb. [Java], 1905, No. 1, pp. 78; abs. in Jour. Landw., 53 (1905), No. 2, pp. 135–172*).—Fertilizer experiments on the Padang Boelan plantation were conducted from 1900 to 1902, inclusive, on soil rich in nitrogen and phosphoric acid but rather low in potash and lime.

An application of nitrogen seemed unnecessary, but the use of potash and phosphoric acid gave good results. The optimum quantity of potash per plant ranged from 1 to 1.3 gm. The use of 0.75 gm. of phosphoric acid per plant proved inadequate. The tobacco grown on this soil had a high nitrogen content, although nitrogen fertilization had little influence. The content of albuminoid nitrogen varied little and amounted to more than 50 per cent of the total nitrogen. The average nicotine content, 1.96 per cent, agreed with the average given by König. It was also observed that light and favorable moisture conditions promote the production of nicotine.

The fermented tobacco contained nitrate nitrogen, the quantity being greater in the lower than in the upper leaves. The percentage of amid nitrogen was lower than that determined by Behrens in European tobacco, and it is believed that the

transformation of albuminoids into amid compounds takes place to a lesser extent in tropical climates. An abnormally high percentage of total nitrogen was generally due to a large quantity of amid nitrogen. The tobacco grown on this plantation graded high in quality.

In studying the total quantity of calcium, magnesium, potassium, and sodium in the ash of tobacco it was found that in 1900 the position of the leaf on the stalk had no significance in this connection, but in 1901 the quantity was greater in the lower than the upper leaves. The average content for the 2 years was about the same. In 1900 the fertilizers applied exerted no influence, while in 1901 the quantity of the inorganic bases was increased somewhat by the use of phosphoric acid and potash. It did not appear that the total quantity of these bases is dependent upon variety and climate alone, the average for the entire plant being independent of weather conditions and, to a small extent, dependent upon fertilization. In the author's opinion a comparison of his own results and those of van Bemmelen with the data published by van Bylert seems to indicate that this factor is dependent upon the kind of soil.

Observations made on the reciprocal substitution of potash and lime indicate that the position of the leaf on the stalk influences its composition, the lower leaves containing more potash and the upper ones more lime. Favorable soil moisture conditions increased the potash and decreased the lime content. The total quantity of lime and magnesia in the entire plant varied with the potash content. The influence of the fertilizers was readily noticeable only when potash was given. Atterberg's method for the determination of plant food requirements of the soil by means of the analyses of the crops produced was applied in connection with these experiments, but in the opinion of the author the results showed that the rules he has laid down may lead to wrong conclusions with tobacco.

The storage and germination of wild rice seed, J. W. T. DUVEL (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 90, pt. 1, pp. 16, pls. 2*).—The distribution, habitat, and germination of the seed of wild rice are discussed; directions for storing the seed, packing it for transportation, and making germination tests are given, and the results of storage experiments reported.

Wild rice seed gathered as soon as matured, covered with fresh water before fermentation had set in, and stored at a temperature of 32° to 34° F., germinated as high as 88 per cent, or fully as good as fresh seed, after being in storage 393 days. Drying the seed, either when fresh or after it is taken from cold storage, destroys its vitality. The best results in germinating this seed were secured by covering it with water and changing the water in the dishes daily.

The seed germinated well at temperatures ranging from 15° to 30° C., and the experiments so far as carried out show that the maximum temperature of germination is about 35° C., but that better results are obtained at lower temperatures. Work of a similar nature has been previously noted (E. S. R., 15, p. 578).

Third annual report of the Central Seed-Testing Laboratory of the Aynsome Agricultural Station, J. S. REMINGTON (*Anysome Agr. Sta., Seed-Testing Lab. Ann. Rpt., 3 (1904-5), pp. 54, figs. 21*).—From September, 1904, to June, 1905, 1,296 seed samples were tested, the largest number being clovers, rye grasses, and seeds of root crops.

In one sample of red clover seed over 200 dodder seeds were found in 1 oz. The average germination for red clover during the season was 93.1 per cent; white clover, 83.5; perennial rye grass, 80.8; and Italian rye grass, 82.9. The germination and purity tests of all the samples examined are tabulated. The weed seeds most commonly found in clover and grass seed samples are enumerated and briefly noted.

The destruction of dodder, E. MARRE (*Prog. Agr. et Vit. [Ed. l'Est], 26 (1905), Nos. 22, pp. 648-654, pl. 1, figs. 4; 23, pp. 684-694, figs. 4; 24, pp. 722-726*).—This article, including a botanical study of different species of cuscuta, describes the means

by which these parasitic plants are disseminated and suggests measures for their prevention and destruction. The text of the French law regarding the destruction of cryptogams and other plants detrimental to agriculture is given in this connection and discussed.

HORTICULTURE.

Study of the causes which make the soil of old market gardens unsuitable for the culture of certain vegetables (*Bul. Mens. Off. Renseig. Agr.* [*Paris*], *4* (*1905*), *No. 9*, *pp. 1079–1082*).—Chemical analysis of old truck garden soil showed it to be more than twice as rich in all the elements of plant food as the best manure, and yet when such plants as corn salad or spinach were planted on this soil the latter part of August only very inferior crops were secured.

Analyses of the matter in the soil soluble in boiling water showed that it contained much less available plant food than the same soil earlier in the spring before cropping had begun. This, then, is considered to be the reason for the defective crops at this time—a lack of immediately available plant food due to exhaustion by 2 or 3 previous crops grown earlier in the summer. When the "dead" soil was treated with a dilute solution of carbonate of potash it was found that practically as much nitrogen and phosphoric acid was made available as was required for the production of good crops earlier in the season.

It is held, therefore, that if these "dead" soils are treated with some other agent which will liberate the potash of the soil in the form of carbonate of potash a full crop is assured.

A rust-resisting cantaloupe, P. K. BLINN (*Colorado Sta. Bul. 104*, *pp. 15*, *figs. 10*).—The cantaloupe rust or blight has for a number of years seriously injured the cantaloupe industry in Colorado in the vicinity of Rockyford. In dry seasons the disease may not excite much notice, while in seasons subject to rains and dews its development is very disastrous to the crop. The disease is caused by a parasitic fungus (*Macrosporium cucumerinum*). Attempts by the station to control the disease by the use of Bordeaux mixture have failed.

In 1903 it was observed that some of the plants in a number of fields which had been grown from a single strain of seed were much more resistant to the rust than others. Seed from these immune plants was obtained and planted in 1904 and likewise in 1905. A large proportion of the seed from these rust-resistant plants produced a healthy growth of vines and large solid melons with firm flesh and small seed cavities completely filled with seed, while unselected seed produced plants greatly injured by the rust, with small melons which ripened prematurely, thin watery flesh, large open seed cavities, and of practically no market value.

Upon investigation it was found that the rust-resistant plants traced back to an accidental selection made some nine years before by J. P. Pollock. In selecting muskmelons for seed attention should be paid to quality as well as rust-resistance. A schedule is given suggesting points which should be observed in melon seed selection. Muskmelons, which, from their outside marking appear to be satisfactory, should be cut open and examined in regard to size of seed cavity, character of flesh, etc. Observation at the station has shown that a close netted melon does not lose weight by evaporation as rapidly as one not so closely netted.

Fertilizer for peas, H. BLIN (*Prog. Agr. et Vit.* (*Ed. l'Est*), *26* (*1905*), *No. 33*, *pp. 294–299*).—A general discussion of the fertilizer requirements of peas, with tables showing the increased yield obtained when potash was used in addition to superphosphates on peas.

Manuring gumbo, H. BLIN (*Agr. Prat. Pays Chauds*, *5* (*1905*), *No. 31*, *pp. 347–352*, *fig. 1*).—An account of fertilizer experiments with gumbo or okra (*Hibiscus esculentus*) in which a complete fertilizer was compared with the different essential fertilizer elements separately.

The results of the experiments, which are tabulated, indicate that potash is especially useful in the culture of this crop. This element seems to especially favor the development of the pericarp or edible portion of the fruit. A formula consisting of 500 kg. nitrate of soda, 800 kg. basic phosphate, and 200 kg. sulphate of potash per acre is recommended as a general fertilizer for this crop.

The mutations of Lycopersicum, C. A. WHITE (*Pop. Sci. Mo., 67 (1905), No. 2, pp. 151–161, figs. 2*).—The author obtained 2 new species of Lycopersicum, which he has designated *L. solanopsis* and *L. latifoliatum*, by mutation from seeds of *L. esculentum*. The essential features of this work have been noted in an earlier publication (E. S. R., 13, p. 645). The author believes that these two cases of sudden mutation in the genus Lycopersicum are of essentially the same nature as those cases of mutation observed by Professor de Vries in the genus Œnothera.

The American peppermint industry, A. M. TODD (*5. Internat. Kong. Angew. Chem., 1903, Ber. 2, pp. 804–812*).—A brief historical account of the peppermint industry since it began in England in 1750, with an account of its culture on the large mint farms in Michigan and of methods of distillation.

Peppermint, ALICE HENKEL (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 90, pt. 3, pp. 15, figs. 3*).—Brief descriptions of American mint (*Mentha piperita*), black mint (*M. piperita vulgaris*), and white mint (*M. piperita officinalis*), with an account of peppermint culture in the United States, including planting, harvesting, distilling, and statistics on the production, export and prices of peppermint oil. Michigan produces the bulk of the crop grown in the United States. The number of acres grown in 1902 was 6,400 with an average yield of 12.8 lbs. of oil per acre. The price in 1905 ranged from $2.25 to $3.45 per pound.

Shading pineapples (*Agr. News [Barbados], 4 (1905), No. 90, p. 292*).—A note is given stating that an experiment was made in shading pineapple plants from the time of flowering until the fruit was ready to be cut. As a result the shaded plants were healthier and the fruits more perfect in shape than those unshaded.

Fertilizing apple trees, F. A. WAUGH (*Country Gent., 71 (1905), No. 2762, p. 14*).—This is an abstract of a paper presented by Prof. W. P. Brooks before the horticultural seminary of the Massachusetts Agricultural College.

Besides the discussion of the general principles which should obtain in the fertilizing of fruit trees, an account is given of an experiment begun in 1887 in which good agricultural land was planted with apple trees and the sections fertilized with different kinds of fertilizers. The trees were planted in 1890, and are now 15 years old. Data as to the fertilizers used and their cost, the average diameter of the trees at present, and the total yield to date are given in the following table:

Yield and growth of fruit trees differently fertilized.

Fertilizer used per acre annually.	Annual cost per acre.	Present diameter.	Total yield to date.
		Inches.	*Pounds*
Ten tons barnyard manure	$20	31.32	10,287
One ton wood ashes	12	27.52	5,463
Nothing		24.52	2,021
Six hundred lbs. bone meal and 200 lbs. muriate of potash	10	26.94	7,111
Six hundred lbs. bone meal and 400 lbs. low-grade magnesia-potash-sulphate	11	31.15	9,607

From the table it is readily seen that the largest trees and the heaviest yields resulted from the use of 10 tons of barnyard manure per acre. Very nearly as good results were obtained on the plat fertilized with bone meal and low-grade magnesia-potash-sulphate. The table likewise shows that the cost per acre was considerably greater when barnyard manure was used than with any of the other fertilizers.

When the muriate of potash was used in the place of magnesia-potash-sulphate the diameter growth of the trees and the total yield were considerably lessened notwithstanding about equal quantities of actual potash were supplied in each instance.

The varieties Baldwin, Gravenstein, Rhode Island Greening, and Roxbury Russet were used in the experiment and showed considerable variation in their responsiveness to fertilizers. The variety Roxbury Russet made very nearly as good growth where no fertilizer was used as where barnyard manure was applied. Baldwin, on the other hand, made a much more vigorous growth on the fertilized than on the unfertilized section.

A considerable difference in the results is noted in the matter of quality of fruit grown on the different sections. The best colored fruit was nearly always found on the plat fertilized with wood ashes, followed by that on the plat which received magnesia-potash-sulphate. The fruits on the unfertilized plat were firm, of good color and good flavor, but were altogether too small and a very large proportion of them was unfit for sale. The fruit on the plat fertilized with barnyard manure was poorest of all except in point of size. It was soft, rather poorly flavored, kept poorly, and was not well colored.

The relation of soil texture to apple production, H. J. WILDER (*Science, n. ser., 22 (1905), No. 570, pp. 715–719*).—The author discusses apple production as related to soil texture, exposure, etc., the discussion being based on the results of work done by the Bureau of Soils of the U. S. Department of Agriculture.

Apple trees grown on a deep sandy soil, while they produce fruit of good quality and color, are so short-lived as to make it inadvisable to plant orchards on this soil except for home use. On the other hand, when the trees are grown on very heavy clay soils, such as the Miami clay loam in Michigan, the Dunkirk clay in the Champlain Valley, the Hagerstown clay in Adams County, Pa., and on the Pikeville area in Tennessee, the apples are inclined to have greasy skins and an inferior color. The most successful commercial orchards are grown on loam soils between these two extremes.

Apple scions from bearing trees—Influence of the stock (*Rural New Yorker, 64 (1905), No. 2907, p. 741*).—In reply to a question as to the influence of selecting scions from bearing trees for top-working purposes the opinions of G. T. Powell, F. A. Waugh, F. W. Card, W. M. Munson, S. G. Maynard, and A. G. Gulley are given. In general, this practice is believed advisable, though no definite experiments on the subject are known to the writers.

Handling the apple crop, H. H. HUME (*Bul. N. C. Dept. Agr., 26 (1905), No. 9, pp. 22, figs. 16*).—Directions are given for harvesting, packing, and marketing apples.

The short apple crop of 1905 (*Amer. Agr., 76 (1905), No. 19, pp. 424, 425*).—The apple crop of the United States for 1905 is placed at 23,495,000 bbls. as compared with 45,360,000 bbls. in 1904, 42,626,000 bbls. in 1903, and 46,625,000 bbls. in 1902.

Pomology of Finistère, J. CROCHETELLE (*Quimperlé, France: Union Agricole, 1905, pp. 52 + 31, figs. 12*).—The author made a study of the apples of Finistère. Descriptions of the varieties grown and analyses of the juice of each variety are given.

Citrus fruit growing in the Gulf States, P. H. ROLFS (*U. S. Dept. Agr., Farmers' Bul. 238, pp. 48, figs. 17*).—Popular directions for the production of citrus orchards in the Gulf States, including all the details of soil selection, varieties, propagation, harvesting, shipping, protection from cold, top working, etc.

Citrus fruits in Hawaii, J. E. HIGGINS (*Hawaii Sta. Bul. 9, pp. 31, pls. 3, figs. 7*).—Directions for the culture of oranges, lemons, pomelos, and limes, with an account of the more serious diseases and insect pests affecting them.

Growing oranges under tents, H. V. HORGAN (*Country Calendar, 1 (1905), No. 8, pp. 717–719, 750, figs. 5*).—An account of the successful culture of oranges in the frosty regions of northern Florida by the aid of paper tents heated with a kerosene lamp during the early growth of the trees and protected later by high board

walls and wood fires. The illustrations given show how the tents were built and heated, the method of construction of the board walls, and the laying of the fires throughout the orchard.

The pomelo (*Mo. Consular and Trade Rpts.* [*U. S.*], *1905, No. 300, pp. 101–103*).—An account is given of the climate and soil requirements and the bearing capacity of Chinese pomelos. It is stated that this is the finest fruit in the far East, and its introduction and commercial culture in the United States are urged.

South Australian fruit at the Brisbane national show, G. QUINN (*Jour. Dept. Agr. So. Aust., 9* (*1905*), *No. 2, pp. 97–103*).—Tabulated data are given showing the date of picking, condition when packed, time of placing in storage, and the keeping quality of 7 varieties of pears, 1 of grapes, and 37 of apples.

Packing and marketing fruits, F. A. WAUGH (*St. Joseph, Mo.: The Fruit-Grower Co., 1905, pp. 63, figs. 12*).—Popular directions for harvesting and marketing the various orchard and small fruits.

Experiments in cold storage of fruit, J. KNIGHT (*Jour. Dept. Agr. Victoria, 3* (*1905*), *No. 2, pp. 158, 159*).—Notes on the keeping quality of a number of different varieties of apples and pears held in cold storage.

Sterilizing fruit (*Ann. Rpt. Bd. Agr. and Dept. Pub. Gard. and Plantations Jamaica, 1905, p. 11*).—An account of the successful preservation of mangoes, pineapples, chocho, gineps, avocado pears, akees, and bananas by canning.

The fruits were sterilized in the cans in a patent apparatus at a temperature of 150 to 155° F. for 4 hours, the water used being sterilized the previous day at 150° F. for 1 hour. The caps were adjusted and fixed with clips before placing the bottles in the water and hermetically closed during the sterilizing process. A bottle of mangoes thus preserved was opened 97 days after canning and found to be in perfect condition.

A method of preventing the rapid decay of ripe fruit (*Jour. Bd. Agr.* [*London*], *12* (*1905*), *No. 5, pp. 305, 306*).—Soft fruits like strawberries were immersed for 10 minutes in cold water containing 3 per cent of commercial formalin. On removal such fruit was immersed for 5 minutes in cold water and afterwards placed on wire netting or some similar open material to drain and dry. With fruit having a rind or skin that is not eaten, like bananas, mangoes, etc., the immersion in water after treatment with the formalin solution is omitted.

Fruits purchased from shops in the market and thus treated kept perfectly sound after a similar quantity of untreated fruit from the same lot had become moldy or decayed, as follows: Cherries 7 days, gooseberries 7 days, grapes 4 days, pears 10 days, and strawberries 4 days. In this experiment all of the fruit treated was perfectly ripe. It is thought that if the fruit had been treated at a little earlier stage the results might have been still better. This method of treatment, it is thought, will be of great commercial importance in shipping tropical fruits.

Preparation of fruit pulp (*Jour. Bd. Agr.* [*London*], *12* (*1905*), *No. 2, pp. 112–115*).—Methods of preparing various fruit pulps are described.

Hard fruits, such as apples and pears, are cut into small pieces without being peeled or having the cores or seeds removed and placed in cold water containing 1.5 oz. of salt to the gallon to prevent discoloration. The fruit is then boiled to a pulp and strained, a yield of about one-fifth the original weight being obtained. Plums and soft fruits are treated in practically the same manner. With plums the strained pulp is sweetened with about 4.5 lbs. of sugar to each cwt. of fruit and the boiling continued until the pulp is thickened sufficiently to hang from the spoon without dropping. With raspberries and strawberries the boiling must not be prolonged and the pulp need not be strained through so fine a sieve as in the case of plums.

"The principal points to which care should be devoted are the processes of boiling the fruit. The first boiling should be continued only so long as the consistency of the mass is such as will enable the pulp to pass through the sieve for straining, and

at the second boiling the pulp must not be allowed to get too thick, otherwise it will acquire a bitter flavor."

The use of lye in fruit canning (*Cal. Fruit Grower, 32 (1905), No. 906, p. 4*).—The method of the California Fruit Canners' Association at San José of using lye for eating off peach skins as a substitute for paring was investigated by a member of the California State Board of Health.

By this process the fruit is immersed in the hot lye and quickly passed into pure cold water, which is constantly changing and quickly washes away the alkali. The process is believed to be entirely cleanly and the fruit healthful, the peaches not being handled as they must be when peeled by hand. Two cans of peaches thus prepared were analyzed with reference to acid content. In both practically the normal amount of acid was found. It is stated that the same process is used with prunes.

Pimento growing in Jamaica, A. ROXBURGH (*Agr. News [Barbados], 4 (1905), No. 90, p. 295*).—Directions are given for growing pimento (*Pimenta officinalis*), or allspice, in Jamaica. The average annual production of pimento in Jamaica is placed at 50,000 to 60,000 bags of about 150 lbs. weight each.

Cultivation of tea in Jamaica (*Agr. News [Barbados], 4 (1905), No. 91, p. 309*).—An account of a tea plantation of 80 to 90 acres located at Ramble in St. Ann, Jamaica. The plantation was set out in 1896, and is at an elevation of 1,600 ft. above sea level. The trees are in good condition and the quality of the tea produced said to be first class. This is stated to be the only tea plantation in the West Indies.

The technology of tea, H. NEUVILLE (*La technologie du thé. Paris: Challamel, 1905, pp. 270, figs. 30*).

Manurial experiments with cacao at Dominica, F. WATTS (*West Indian Bul., 6 (1905), No. 3, pp. 258-262*).—The value of various fertilizers and mulches for cacao was studied in plat experiments for each of the years 1903 to 1905. The largest yield of wet cacao for the whole period was obtained on a plat mulched with grass and leaves. Next to this stood the plat fertilized with dried blood. Phosphates and potash, while increasing the yields by 25 to 30 per cent over no manure, were not as effective as either dried blood or simple mulching. It is believed that the method of manuring by means of a mulch of grass and brush is the proper course to adopt in Dominica for cacao.

Grafting cacao, J. JONES (*Agr. News [Barbados], 4 (1905), No. 94, p. 359*).—In grafting experiments it was found that the tiger cacao (*Theobroma bicolor*) was not suitable as a stock for the alligator cacao (*T. pentagona*). A good growth was secured when *T. pentagona* was grafted on *T. cacao*.

[Notes on varieties of chestnuts] (*Rural New Yorker, 65 (1905), No. 2920, p. 24, fig. 1*).—Notes are given on the yield and characteristics of 9 varieties of chestnuts under culture, and an account of the fruiting of several crossbred seedlings between Paragon and Japanese varieties now 6 years old.

These seedling trees are stated to be fairly intermediate between the parents, but the nuts and burs resemble the Japanese varieties. The nuts though large are of indifferent quality. The fruiting of seedling hybrids of Paragon and our native wild chestnuts is also noted. Crosses are also being made between chinquapin and Paragon, Ridgely, and many of the best Japanese varieties of chestnuts. It is hoped to blend the large size of the chestnut with the quality, prolificness, and early bearing habit of the chinquapin.

Systematic amelioration of grapes by the graft, A. JURIE (*Jardin, 19 (1905), No. 449, pp. 332, 333, figs. 2*).—A contribution to the subject with illustrations showing the amelioration in fruit production secured as a result of grafting and analyses showing changes in the composition of the wine produced.

Fertilizer experiments with grapes, H. SCHELLENBERG (*Landw. Jahrb. Schweiz, 19 (1905), No. 5, pp. 296-300*).—The results are given of fertilizer experiments with grapes carried on since 1891 at the horticultural experiment station in Wädensweil.

Plat 1 in the experiment was heavily fertilized during each of the years 1891 to 1904 with cattle manure. Plats 2 and 3 received during each year of the same period, except in 1894, 1,200 kg. of Thomas slag and 900 kg. of kainit per hectare. In addition plat 2 received each year liquid manure and plat 3, 450 kg. of nitrate of soda per hectare. Plat 4 received no Thomas slag or kainit, except in the year 1894.

The average yield of fruit during the 13 years of the experiment on the different plats was as follows: Plat 1, 5,547 kg.; plat 2, 5,485 kg.; plat 3, 5,430 kg.; and plat 4, 4,669 kg. The largest fruit on an average was secured on plat 3. The largest amount of second-class fruit, 9.5 per cent, was found on plat 1, and the smallest amount, 4.7 per cent, on plat 4. The wine produced was of practically like quality on each of the different plats.

Analyses of soils and the interpretation of the analytical results in the manuring of grapes, A. HUBERT (*Prog. Agr. et Vit. (Ed. l'Est), 26 (1905), No. 50, pp. 690–699, fig. 1*).—Chemical and physical analyses with descriptions of the methods employed are given for a number of different soils, together with a table showing the amounts of different kinds of nitrogenous, potassic, and phosphatic fertilizers to use on different classes of calcareous and noncalcareous soils.

Roses and how to grow them (*New York: Doubleday, Page & Co., 1905, pp. X+189, pls. 32, figs. 4*).—A popular manual containing directions for growing roses in the garden and under glass, and designed more especially for the use of the amateur. Much of the matter in the book has already appeared in magazine form.

Carnation breeding, C. W. WARD (*Gardening, 14 (1906), No. 321, pp. 129, 130, figs. 3*).—Brief historical notes on the carnation, with an account of the author's methods of breeding carnations by hybridization and selection.

It is stated that the annual value of the carnation product is between $5,000,000 and $6,000,000. A half interest in the variety Robert Craig, originated by the author, is stated to have brought $10,000. The bulk of the profitable varieties originated by the author trace back to the variety General Maceo, which was a cross between the English variety Winter Cheer and the American variety Meteor.

The chrysanthemum, A. HERRINGTON (*New York: Orange Judd Co., 1905, pp. VIII+160, pl. 1, figs. 32*).—Directions are given to professional growers and amateurs for the culture of chrysanthemums.

The main portion of the book is devoted to the production of large flowers such as are seen at exhibitions and in flower stores. The work takes up in systematic detail culture directions, beginning with the taking of the cuttings to the staging of the blooms. Chapters are also given on raising chrysanthemums from seed, hybridizing chrysanthemums, insect pests, and diseases.

A chemical study on the culture of chrysanthemums, A. HÉBERT and G. TRUFFAUT (*Bul. Soc. Chim. Paris, 3. ser., 33 (1905), No. 11, pp. 661–664*).—The authors cultivated the variety of chrysanthemums Madame Gustave-Henry out-of-doors in a rich soil without the addition of fertilizers, and analyzed the plants at 2 different stages of growth.

At the time of the first analysis, July 28, the plants had been growing 178 days and the first buttons were appearing. Sixty-four days later, during the first days in October, when the plants were in full bloom they were analyzed again. During the last 64 days of growth the plants took daily 3 times as much nitrogen, 3 times as much potash, 7 times as much phosphoric acid, 16 times as much lime, 20 times as much magnesia, and 5 times as much sulphuric acid as during the preceding 178 days.

It appears, therefore, that the most active growth of the chrysanthemum begins during August and it is at that time that special attention to watering and the use of soluble manures should begin. The analyses further show that for each part of nitrogen taken from the soil during the first period of vegetation there was withdrawn 1.42 parts of potash and 0.28 part of phosphoric acid, while during the second

period of vegetation there was withdrawn for each part of nitrogen 1.23 parts of potash and 0.47 part of phosphoric acid.

The usual fertilizers actually employed in the growing of chrysanthemums, such as night soil, are shown by analysis to contain 0.23 part of potash and 0.13 part of phosphoric acid for each part of nitrogen in the fertilizer. These proportions are not in harmony with the proportions as found by analysis of the plant and it is therefore believed that this accounts for the unfavorable results secured when this fertilizer is used alone for chrysanthemums.

A study of perennial garden phlox, C. J. HUNT (*Country Life Amer., 9 (1905), No. 1, pp. 66–69, figs. 11*).—Directions for the culture of phlox with lists of the best varieties to plant. The varieties noted are described in accordance with the recent color chart worked out by the French National Chrysanthemum Society.

The culture of fringed gentian, T. MURRAY (*Gard. Mag. [N. Y.], 2 (1905), No. 5, pp. 210–212, figs. 9*).—The author succeeded in growing fringed gentian (*Gentiana crinita*) as a garden plant. The plant appears to be a biennial, since seeds sown in the spring form only a rosette of leaves during that season and come into blossom the succeeding season. The seed is first sown in a cold frame on a bed of chopped sphagum moss and then transplanted to beds, handling it in much the same manner that poppy seedlings are handled.

New creations in plant life, W. S. HARWOOD (*New York and London: The Macmillan Co., 1905, pp. XIV+368, pls. 49*).—A popular and somewhat laudatory account of the work of Luther Burbank in the development of new varieties of fruits, nuts, vegetables, forage plants, and trees, with details of his methods of work and his theories in regard to the production of new varieties. Much of the matter contained has appeared in magazine form.

FORESTRY.

A handbook of the trees of California, ALICE EASTWOOD (*Occas. Papers Cal. Acad. Sci., 1905, No. 9, pp. 86, pls. 57*).—This is a concise popular manual of the trees of California. Such additional trees as grow in Washington, Oregon, and Arizona have also been included.

The book is arranged with 3 keys for the purpose of easy identification. In the first key the trees are arranged according to the leaves and in the second according to the fruits. The third is a regular scientific key based upon the botanical characteristics of flowers, fruits, and leaves. Illustrations are given of some portion of practically all of the California trees. A large proportion of these were prepared by Dr. A. Kellogg, one of the founders of the California Academy of Sciences.

Advice for forest planters in Oklahoma and adjacent regions, G. L. CLOTHIER (*U. S. Dept. Agr., Forest Serv. Bul. 65, pp. 46, pls. 4, figs. 7, map 1*).—A number of forest planting plans adapted for use in Oklahoma and portions of Indian Territory, Kansas, Colorado, Texas, and New Mexico are here presented. A planting plan is a detailed statement of all the operations necessary to establish and maintain a forest plantation upon a specific tract of land.

Report Irish Forestry Society (*Irish Forestry Soc. Ann. Rpt. 1904, pp. XII+84*).—Besides a general account of the work of the year by the secretary, J. S. Kerr, and a statement of accounts, the report contains a number of prize essays on the present condition and future prospect of forestry in various districts of Ireland.

Annual progress report of forestry administration in the Central, Oudh, and school circles of the United Provinces for the forest year 1903–4, L. MERCER, C. E. MURIEL, and H. JACKSON (*Ann. Rpt. Forest Admin. Cent., Oudh, and School Circles [India], 1903–4, pp. 174*).—This consists of the usual statements in regard to the constitution of the state forests, management, protection, sylviculture, exploitation, financial results, and administration for each of these provinces, with

appendixes showing in tabular detail the area of the different forests, cuttings, receipts, disbursements, etc.

Transplanting of bigtree seedlings, S. J. Flintham (*Forestry and Irrig., 11 (1905), No. 9, pp. 428–430*).—The author notes the results of successful experiments of ranger L. L. Davis, in charge of the General Grant National Park, in transplanting naturally sown Sequoia seedlings.

Most of the plants set out were from 4 to 18 in. in height and were from 2 to 3 years old. These had taproots often 1 to 2 or more feet long. Some 1-year-old plants which were 1 to 4 in. high were set out, but these did not succeed so well, as in the dry season the roots did not reach down to permanent moisture. The larger seedlings were quite hardy as to drought and frost even at elevations of 6,000 to 7,000 ft.

Seed bed fertilizer experiments on sandstone soils, Vater (*Tharand. Forstl. Jahrb., 55 (1905), No. 2, pp. 116–137*).—A detailed account is given of experiments to determine the effects of fertilizers in growing seedling spruces and pines.

In the first experiment the seed beds were located on sandstone soil of the second to third class. The fertilizers used were kainit, potassium chlorid, and potassium sulphate. Spruce seed was planted. The tabulated results show that the height growth of the seedlings was doubled and the mass growth trebled by the use of the fertilizer, the largest seedlings as regards height and weight being produced on the plat fertilized with kainit, closely followed by that fertilized with potassium chlorid. The potassium chlorid gave about 20 per cent better results as regards growth than the potassium sulphate.

Experiments with both pine and spruce seed on sandstone soil of the fourth quality gave results similar to those noted above as regards the beneficial effects of fertilizing seedlings. In one experiment the fertilizers were not applied until the seedlings were a year old. At the end of the following season they had made practically 40 per cent better growth than the unfertilized seedlings

Analyses are given of the different soils used and results included of some experiments by other investigators along similar lines.

The natural replacement of white pine on old fields in New England, S. N. Spring (*U. S. Dept. Agr., Bur. Forestry Bul. 63, pp. 32, pls. 4, map 1*).—This bulletin deals primarily with the life history of second-growth white pine on old fields and pastures in New England. Its object is to furnish such information about the characteristics of the white pine and the conditions governing its growth as will be of practical help to people in New England interested in the profitable growth of this timber.

At present merchantable stands of white pine in New England are being rapidly removed and commonly no seed trees are left to provide for future stands. Unless such seed trees are left the future extension of white pine forests in New England will be limited to occasional small groups, leaving much of the land to be occupied by inferior species. If seed trees are left it is thought probable that the number of stands of merchantable pine in New England will be greater 50 years hence than it is to-day and the quality of the timber better.

A white pine does not begin to bear full crops of cones until about 35 years of age. The heaviest seed years are from 5 to 7 years apart. Tests indicate that from 10 to 20 per cent of fresh white pine seed will not germinate. Seedlings grow very slowly but after that stage is past the growth is rapid for 50 to 60 years. The most rapid rate of growth occurs when the tree is from 30 to 40 years of age.

Tables are given showing the contents in cords of white pine trees of different diameters. A map is included which indicates where forests of various types of white pine in New England are found. Counts of seedlings 2 to 8 years old in typical white pine areas averaged 2,113 trees of all species per acre. Of these 80 per cent were white pine and 20 per cent birch and less valuable species. In regions of New

England where natural replacement can not be secured for lack of seed trees the planting of white pine is advised. A number of tables showing the composition of white pine stands at different periods of maturity are given. Pruning in young white pine forests is thought expensive and inadvisable.

In lumbering, it is recommended that 3 to 4 short-bolled and wind-firm seed trees be left per acre to insure the replacement of pine. The profits in second-growth white pine are shown to be as high as 11 per cent where the land is valued at not over $4 per acre, the annual outlay not over 12 cts. per acre, and the stumpage price of wood not less than $5 per cord. The highest rate of interest is secured if the trees are cut when from 35 to 45 years of age.

Loblolly pine in eastern Texas with special reference to the production of cross-ties, R. Zon (*U. S. Dept. Agr., Forest Serv. Bul. 64, pp. 53, pls. 4, figs. 2*).—The author made a study of the occurrence, manner of growth on different soils and in different mixtures, and of the uses of loblolly pine in eastern Texas.

Tables are given showing the composition of loblolly pine forests 35 to 40 years old on wet prairie, forests 24 and 60 years old on fairly well-drained light soils, mixed pine and hard wood forest 150 years old on poorly-drained soil, and 30 to 40 years old on well-drained fertile soil, and forests 10 to 29 years old on old fields. Normally this tree grows to a height of 90 to 110 ft. and has a diameter of 2 to 2.5 ft. It matures at 70 to 80 years of age. Its best growth is found on a deep, fairly loose sandy or light loamy moist soil. It is intolerant of shade during middle and later life. It begins seed production when about 30 years of age. Tables are given showing the rate of height and diameter growth of the tree on different soils and in different mixtures.

About 300,000,000 ft. of loblolly pine lumber is annually turned out by the mills of Texas. The lumber is usually sold under the name of short-leaf pine. The large proportion of sapwood which loblolly pine usually contains makes it desirable to kiln dry it immediately after it is sawed to avoid the attack of a fungus which stains it blue. The untreated timber readily rots in exposed situations, but when treated with preservatives outlives either the short-leaf or long-leaf pine.

The volume yield of loblolly pine at different stages of growth is tabulated. By present methods of cutting pole ties, the author shows that from 54 to 71 per cent of the timber goes into slabs and excessive dimensions and is thus wasted. Tie cutters prefer trees 10 to 15 in. in diameter or between 30 and 50 years of age. The author shows that this is the period of most rapid growth of the trees and from the standpoint of profits and economy only trees 15 to 17 in. through should be used. About 80 per cent of the loblolly pine now standing in Texas is of tie size. In discussing a loblolly pine forest as an investment, the author shows a probable return of about 5 per cent on a 40-year investment.

Cultivation and commercial fertilizers for stunted pine stands of the Würtemberg Black Forest, F. Hofmann (*Allg. Forst u. Jagd Ztg., 81 (1905), Sept., pp. 297–307, dgm. 1*).—In a pine forest 20 to 25 years of age which had made very poor growth because of poor soil, extensive development of weeds and grass, etc., an experiment was made to determine the value of cultivation.

Thomas slag, ammonia, superphosphate, and kainit were also used experimentally on young plantations of pine and spruce. The experiments were begun in 1900 and the results secured up to 1904 are discussed. Cultivation alone proved sufficient to thoroughly rejuvenate and start into good growth the older forest of pine. Among the fertilizers tested Thomas slag proved especially effective. General suggestions based on the author's observations are given for forestry practices on poor soils.

Spruce seed sown broadcast, A. Knechtel (*Forestry and Irrig., 11 (1905), No. 9, pp. 430, 431*).—It has been commonly observed that evergreen trees spring up readily in poplar groves. The belief has become prevalent, therefore, that spruce finds in such places good conditions for reproduction.

In order to test this matter about a bushel of native spruce seed was sown in 1903 in such a grove. The poplars ranged in diameter from 4 to 10 in. The seed was scattered on fallen leaves, decaying wood, and on all spots where the mineral soil was exposed. About 8 qt. of seed was used per acre. An examination of the area in July, 1904, showed that where mineral soil had been exposed and on rotten wood the little trees were doing well and in many places 4 or 5 trees were found per square foot. Where the leaves were thick, however, the trees were scarce.

It is believed that over the whole ground they were sufficiently numerous to make a satisfactory evergreen forest if they all continue to grow. A further examination in August, 1905, showed that the trees were still alive and about as numerous as the preceding year.

The influence of different degrees of thinning on the stem form of spruce, M. KUNZE (*Tharand. Forstl. Jahrb., 55 (1905), No. 2, pp. 138–150*).—Diameter measurements of the boles of 228 trees selected from a section of a forest which had been (a) lightly thinned and (b) medium thinned, and of 187 trees selected from a section (c) strongly thinned, are given in an extended series of tables. The trees were about 83 years old at the time of the measurements and many in the strongly thinned section had been broken by a storm. The measurements are given without conclusions.

The maple sugar industry, W. F. FOX and W. F. HUBBARD (*U. S. Dept. Agr., Bur. Forestry Bul. 59, pp. 1–45, pls. 8, figs. 10*).—The history of the maple sugar industry is briefly outlined and data given on its present status.

It appears that about seven-eighths of the maple product sold to-day is spurious. Since 1850 there has been a gradual decrease both in quantity of sugar and in the sugar-producing area of the country. The various sugar maple trees are briefly described and suggestions given regarding the improvement of mature dense maple groves for sugar-making purposes, and of open groves, dense young groves, and thickets. An ordinary mature thrifty maple will produce about 12 gal. of sap or 3 lbs. of sugar per season. The sap is stated to contain on an average about 3 per cent of sugar.

Directions are given for the manufacture of sugar and sirup, including the tapping of the trees, gathering of the sap and its evaporation, with the estimated cost of the various operations. A grove in which the ground is well shaded and which each season carries a heavy carpet of leaves is thought best for sugar crops, since the trees are less exposed to undesirable extremes of temperature during the sap season.

Germinating Para rubber seeds (*Agr. News [Barbados], 4 (1905), No. 90, p. 293*).—Platforms were erected about 4 ft. from the ground and over these old sacking was stretched. They were then covered over with a little powdered charcoal and the seeds placed on this and covered with more sacking and the whole kept damp by occasional watering. As the seeds sprouted they were removed and potted. Seventy-five per cent of a case of seeds received from Peradeniya germinated after this treatment, notwithstanding they had been delayed over 3 weeks in transit.

The cultivation and preparation of Para rubber, W. H. JOHNSON (*London: Crosby Lockwood & Son, 1904, pp. XII+99, pls. 5, fig. 1*).—Directions are given for the culture of Para rubber, including methods of tapping, preparation of rubber from the latex, yield of Para rubber from cultivated trees in Ceylon, Malay Peninsula, and the Gold Coast, and the commercial value of the oil in hevia seeds.

The rubber industry in Peru, J. M. VON HASSEL (*La industria gomera en el Peru. Lima: Opinión Nacional, 1905, pp. 29, figs. 4*).—This is a popular pamphlet on the rubber industry in Peru, with notes on the species grown, distribution, climatology of different sections, cultural methods, and the future of the industry.

Report on rubber in the Gold Coast, W. H. JOHNSON (*Gold Coast, W. Africa: Dept. Agr., 1905, pp. 15*).—Statistics are given of the rubber production of the Gold

Coast for the years 1880 to 1903, inclusive, and of the results of experiments in growing exotic rubbers.

The quantity of rubber exported from the Gold Coast has decreased from the maximum production in 1898 of 5,984,984 lbs. to 2,258,981 lbs. in 1903. A number of species of foreign rubbers have been grown in the botanic gardens of Aburi. Of these, *Hevea brasiliensis* has given the best results, considerably surpassing in yield and quality of rubber the native *Funtumia elastica*.

The experiments indicate that trees of *F. elastica* should not be tapped before they are 9 years old. Trees of *H. brasiliensis*, 10 years old, yielded on an average 1 lb. ¾ oz. per tree, while the largest yield from trees of *F. elastica*, 7 to 9 years old, was 4 oz. Not only does *H. brasiliensis* grow faster than *F. elastica* and yield a larger amount of rubber of better quality, but it is also freer from insect pests and fungus attacks.

Investigations of kickxia caoutchouc from Cameroons (*Tropenpflanzer, 9 (1905), No. 10, p. 590*).—Analysis of the caoutchouc from this plant showed 3.5 per cent water, 87.2 per cent best quality caoutchouc, 0.5 per cent poor quality caoutchouc; 7.1 per cent caoutchouc resin, and 1.7 sand, etc.

Hand book of timber preservation, S. M. Rowe (*Chicago: Pettibone, Sawtell & Co., 1904, souvenir ed., rev., pp. 203+IV, pls. 20, figs. 58*).—The methods, appliances, and materials used for preserving timber on a large scale are discussed at length for various woods, many illustrations being given of the appliances used in preparing the material and applying the preservatives.

A new impregnation treatment for wood, G. Janka (*Centbl. Gesam. Forstw., 31 (1905), No. 10, pp. 397–401*).—The Rüping system of timber preservation is described.

In the case of railroad ties, the ties are first submitted to a pressure of 5 atmospheres. While still under this pressure they are immersed in coal tar oil and the pressure gradually raised according to the character of the timber to a maximum of 15 atmospheres. The oil is then drawn off and the release of pressure facilitates the driving out of much of the oil that entered the wood.

It is claimed that where 36 kg. were formerly necessary for impregnating a sleeper having 0.11 cu. meter content but 5.5 kg. are required by the Rüping system. It is estimated that the German railroads use annually about 200,000 tons of coal tar oil as a preservative for railroad ties, and that under the Rüping system but 30,000 tons will be required.

Turning sawmill waste into water-white turpentine (*Fla. Times-Union, 1905, Oct. 27, p. 6*).—A description is given of a successful commercial plant for extracting water-white turpentine from sawdust by means of retorts into which steam is injected. It is claimed that from 5 to 15 gal. of water-white turpentine can be obtained by this process in less than an hour from 2 tons of sawdust.

DISEASES OF PLANTS.

Fungus diseases in India in 1903, E. J. Butler (*Ztschr. Pflanzenkrank., 15 (1905), No. 1, pp. 44–48*).—A condensed account is given of the parasitic fungi observed on a number of economic plants in India during 1903. These are grouped according to host plants into diseases of cereals and fodder plants, vegetables, sugar cane, tea and coffee, palms, forest trees, etc.

Among the principal diseases of cereals the author notes the occurrence of a number of species of rusts and smuts, and for the prevention of the latter he suggests soaking the seed preliminary to sowing in a ½ per cent solution of copper sulphate.

A wilt disease of pigeon pea, due to the fungus *Neocosmospora vasinfecta*, is reported as quite common wherever this plant is cultivated. The early and late blight of potatoes are prevalent, and a disease of eggplants, due to an undetermined species of Colletotrichum, is reported.

Among the diseases of sugar cane the most serious is said to be due to *Colletotrichum falcatum*, which causes the red rot. The smut (*Ustilago sacchari*) and the brown spot of the leaves due to *Cercospora longipes* are reported as having been observed, but so far *Trichosphæria sacchari* and *Thielaviopsis ethacethicus* have not been reported.

A number of serious pests of the tea and coffee plants are reported, among them the alga (*Cephaleuros virescens*), the gray blight of tea (*Pestalozzia guepini*), *Cercospora theæ*, thread blight (*Stilbum nanum*), a root disease due to *Diplodia* sp., and the rust (*Hemileia vastatrix*).

Among the diseases of forest trees the spike disease of sandalwood, which is said to resemble the peach yellows of this country, is briefly described, and notes are given on a number of other species of considerable importance.

Some investigations of plant diseases (*Rpt. Expt. Farms. Cent. Prov. [India], 1903-4, p. 17*).—Notes are given on a number of diseases, among them the smut of cereals, for the prevention of which the author recommends immersing the seed in a solution of copper sulphate for 5 minutes as a most satisfactory treatment for use in India. A disease of pigeon pea (*Cajanus indicus*) is briefly described, the disease being some form of wilt. It is thought probable that the disease is due to some soil fungus. Wheat rusts are briefly commented upon and a report given of a test of 115 varieties for rust resistance.

Frost blisters and their origin, F. NOACK (*Ztschr. Pflanzenkrank., 15 (1905), No. 1, pp. 29-43*).—The blisters noticed on the leaves of a number of plants are described and explanations offered as to their origin. The first noticed were on the leaves of alfalfa after a period of low temperature when the thermometer registered —3° C. The action of freezing in withdrawing the water from the cells into the intercellular spaces, where ice masses are formed, is described, and it is thought probable that the elasticity of the underlying parenchyma resulted in its separation from the epidermis. The intrinsic differences in plants in regard to injury by frost are discussed, and the localization of injury, influence of structure, etc., are commented upon.

Internal infection of the wheat grain by rust, H. L. BOLLEY and F. J. PRITCHARD (*Science, n. ser., 22 (1905), No. 559, pp. 343, 344*).—It has been generally assumed that rusts of cereals grow only in the leaves and stems, but recent observations at the North Dakota Station have convinced the authors of the probability that rust of wheat may sometimes persist perennially. Field experiments have indicated that the rust either attacks wheat from the soil in some form, or it may in some manner be communicated through the seed. This latter hypothesis suggests the mycoplasm theory of Ericksson, but the authors think they have a more rational explanation than that offered by Professor Ericksson.

Observations made on numerous samples of wheat harvested from the badly rusted crop of 1904 allow the authors to make the statement that wheat grains from badly rusted plants are very often and in some strains are quite uniformly internally affected by wheat rust filaments to such an extent that both summer and winter spores are produced beneath the bran layer of the grain. In some samples of rust-infected wheat as high as 30 per cent of all grains examined were infected with the stem rust (*Puccinia graminis*), and spore beds bearing both uredospores and teleutospores were found located beneath the bran layer of the grain, usually about the embryo wheat plant. These spots bearing the spores are most commonly located immediately at the germ end, causing a blackened or blighted appearance, but are often found on other portions of the berry, especially along the margin of the grooves. Grains thus affected were found to germinate as freely as other wheat grains.

The observations thus far made have not definitely shown that wheat rust attacks may come in this direct manner from the seed, but if later experiments confirm this

possible mode of propagation the necessity for proper seed selection and grading in farm practice will become very evident.

Symbiosis in Lolium, A. NESTLER (*Sitzber. K. Akad. Wiss.* [*Vienna*], *Math. Naturw. Kl.*, *113* (*1904*), *No. 8–9, pp. 529–546, pl. 1; abs. in Bot. Centbl.*, *98* (*1905*), *No. 18, pp. 451, 452*).—A brief review of literature relating to the fungus occurring in *Lolium temulentum*, *L. perenne*, and other species is given, after which the author describes investigations with the two above-named species, experiments on the pure cultures of the fungus from the darnel, and a peculiar malformation that is possibly due to the fungus.

The fungus is said to be found only in the stems during the growing season and never in the leaves or roots, and there seems to be a true symbiosis between the host and the parasite. The author could not find any evidence to show that the grain of the infested plants was any better developed than those free from the fungus. A greater proportion of seeds of *L. temulentum* is affected by the fungus than of *L. perenne*, only 28 per cent of the latter being found to contain the fungus hyphæ. It is thought that the symbiosis between the fungus and the perennial rye grass is not as yet so well established as is the case with the darnel.

A description is given of a curious growth in many seedlings of darnel. The growing stem seems in some way to be caught in the leaf sheath, causing it to form a loop, which finally bursts through and resumes its upright growth. That this is wholly due to the presence of the fungus is questioned.

A contribution to the biology of ergots, R. STÄGER (*Centbl. Bakt.* [*etc.*], *2. Abt.*, *14* (*1905*), *No. 1, pp. 25–32*).—In a previous publication (E. S. R., 16, p. 985) attention was called to inoculation experiments with various species of Claviceps, in which biological races were shown for the fungus. The identity of several species which had been hitherto considered distinct was pointed out, but the identity of species occurring on *Brachypodium sylvaticum* and on *Milium effusum* was not fully determined.

In the present paper the same species of Claviceps is said to infest each of the above species of grass, as was shown by numerous inoculation experiments, and the author believes that this species is probably a biological form of the ergot occurring on rye. It is believed probable that in nature this species is able to infest through its biological forms both of the species of grass enumerated above. There seems to be a kind of heterœcism between the different forms. On Milium the ergot forms conidia and very rarely normal sclerotia, while upon Brachypodium it forms conidia and well-developed sclerotia.

Black scab of potatoes, J. W. EASTHAM (*Year Book Col. Agr. and Hort. Holmes Chapel, 1904, pp. 11–13, pl. 1*).—A description is given of the black scab of potatoes, due to *Chrysophlyctis endobiotica*. This disease was first noticed and described on potatoes grown in Hungary in 1896, and was first recorded in Great Britain in 1900. Since that time it has spread to various parts of Great Britain, in some cases causing considerable loss.

The disease must not be confounded with the true scab, which forms rusty patches caused by a corky thickening of the epidermis of the potato. In the black scab the potato puts out various excrescences, which are of irregular growth, wrinkled, and wartlike. Not only the tubers, but the underground stems and the bases of the stems above ground are subject to attack by this fungus.

Investigations have shown that the fungus is capable of withstanding the action of lime, frost, etc., when in a resting stage, and that its attacks are most severe on light dry soils.

As preventive treatment, the author suggests the destruction of all diseased potatoes by burning, or feeding them after being thoroughly cooked. Winter plowing or the use of lime in autumn or winter seems to be without effect, although the application of lime in May has apparently some influence in retarding the disease.

The thorough use of sulphur on and about the seed potatoes is also suggested as a means of partial control.

It is stated that the investigations indicate the possibility of the fungus remaining in the soil for more than 6 years.

Methods of spraying cucumbers and melons, W. A. ORTON and W. D. GARRISON (*South Carolina Sta. Bul. 116, pp. 36, pls. 4, figs. 2*).—This bulletin gives an account of experiments carried on in cooperation between the South Carolina Station and the Bureau of Plant Industry of this Department.

In 1903 a severe epidemic of cucumber powdery mildew prevailed in the vicinity of Charleston, S. C., and in the fall of that year and the spring of 1904 and of 1905 experiments were conducted for its control. The authors describe the experiments in detail, and the practical conclusions as well as descriptions of the fungi are given, which are identical with those in Farmers' Bulletin No. 231 of this Department (E. S. R., 17, p. 672).

The inspection and disinfection of cane cuttings, N. A. COBB (*Hawaiian Sugar Planters' Sta., Div. Path. and Physiol. Bul. 1, 2. ed., pp. 35 + VI, pls. 8*).—The purpose of this bulletin is to call attention to the fungus diseases of cane that gain entrance through the cuttings, and to offer suggestions for their prevention. The author recommends selection of growing cane, inspection at time of harvesting, rejection of all diseased or suspected canes, care in making the cuttings, and treatment with fungicides, particularly with Bordeaux mixture. Several plans for treating cane in large quantities are described.

Preliminary notes on root disease of sugar cane in Hawaii, L. LEWTON-BRAIN (*Hawaiian Sugar Planters' Sta., Div. Path. and Physiol. Bul. 2, pp. 39, figs. 12*).—The author describes a number of diseases of sugar cane, the most important of which is the root disease. This disease, which is of fungus origin, has caused the abandonment of the cultivation of Lahaina and Rose Bamboo canes in certain localities.

The first symptoms of the disease are observed in the appearance of the plants, which seem to be suffering as from drought. The leaves stand upright, are rolled together, turn yellow, and gradually become dry. The lower leaf sheaths become matted together about the base of the stem, and a white fungus mycelium is found among them.

In Hawaii the root disease is also said to affect germination. The fungus (*Marasmius sacchari*) is essentially a soil fungus and is able to live as a saprophyte on dead organic matter in the soil, especially about the base of the cane stools.

The treatment recommended is the planting of resistant varieties, cultivation and liming the soil, destruction of diseased material, and when severe the abandonment of cane cultivation for a time. Ratooning is not considered advisable where the disease is prevalent.

The third report on gumming of the sugar cane, N. A. COBB (*Hawaiian Sugar Planters' Sta., Div. Path. and Physiol. Bul. 3, pp. 46, figs. 12*).—In continuation of the publications of the author while in Australia, notes are given on the gumming of sugar cane, which is of bacterial origin.

The author reviews some of the previous publications regarding this disease and describes recent investigations as to its origin, spread, etc. In conclusion he states that the disease, which is a very distinct one, was first discovered in Australia and is due to *Bacterium vascularum*. While the course of the disease is somewhat slow, it often destroys plants and may cause serious losses to the sugar industry. The disease may be recognized by the appearance of a yellowish gum or slime on the ends of freshly cut stalks. This first appears at the ends of the fibers, but finally runs together into large drops.

The disease is particularly connected with the vascular bundles, but may extend into the parenchymatous tissue, especially at the base of the arrow, where it causes a

kind of top rot characterized by the presence of much slime in cavities near the top of the stalk. Different varieties of cane vary in their susceptibility to disease, some being practically immune. It is said to be of easy control through the selection of sound cuttings and the use of resistant varieties. Attention is called to the liability of its transfer from one country to another through the medium of slightly diseased cuttings.

The red string of the sugar cane, R. G. SMITH (*Proc. Linn. Soc. N. S. Wales, 29 (1904), pt. 3, pp. 449-459, pls. 3*).—The presence of red-colored fibrovascular bundles in sugar cane is said to be not at all uncommon, the phenomenon appearing to accompany several diseases of the cane, as well as in some instances occurring in canes that are apparently healthy.

The author gives a description of a form investigated, to which the name red string is given. This was observed in canes otherwise healthy, as well as in plants affected with gummosis. Portions showing the red coloration were cut out of cane and transferred to culture media, from which the author obtained a mold and several species of bacteria. The mold was found under certain conditions to produce the reddish color, but did not produce any slime, while the bacteria produced the characteristic slime. Of the 3 species of bacteria isolated only one was found capable of producing the crimson red gum in the vessels of the cane. This organism was studied and is described under the name *Bacillus pseudarabinus*, n. sp.

The red mold was also studied and is described at some length. The author was unable to associate it with any hitherto described species, but from his characterization he thinks it will be possible for other investigators to recognize it.

The crown-gall and hairy-root diseases of the apple tree, G. G. HEDGCOCK (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 90, pt. 2, pp. 7, pls. 3*).—A preliminary report is given of investigations on the crown-gall and hairy-root diseases of the apple tree, for the purpose of calling the attention of apple growers to the different diseases and to interest them in the collection of data regarding the predisposition of varieties to these diseases.

The author's investigations have resulted in separating what was previously called the apple crown gall into two diseases. The disease now designated as crown gall is a callous-like gall growth following wounds on some portion of the root system of the tree and which rarely occurs above the ground on parts of the trunk or limbs.

The malady now called hairy-root disease is evidently the same as the one first named in New York State Station Bulletin 191 (E. S. R., 13, p. 148) and is characterized both in seedlings and in grafted or budded trees by a stunted root system, accompanied with an excessive production of small fibrous roots, often originating in clusters from the main or tap root. Galls often occur in connection with the hairy root, but these are the results of wounds rather than a form of the disease.

The apple crown gall is of two types. In one a hard callus is formed on grafted trees at the union of the root and scion, or at any other point of the root system where wounds occur, and the results of extensive inoculation with this type have failed to prove that this disease is of a contagious nature. The second type is a soft form more common on seedlings, occurring rarely on grafted trees. These softer galls resemble those of the raspberry and peach, in that they are soft and often rot off, but it is not certain that they are replaced the following year by a new growth, nor is there any proof that they are of a contagious nature.

Nurserymen are advised to give careful attention to the selection of seedlings for grafting and budding, rejecting all that show tufted or hairy roots, as these will develop into hairy-rooted trees with a very deficient root system. So far as the investigations go, this disease is not contagious. It is hoped that in the near future practical means for reducing the percentage of trees affected with these diseases will be known.

A new apple rot, B. O. LONGYEAR (*Colorado Sta. Bul. 105, pp. 12, pls. 4*).—There has been recently observed in Colorado a widely distributed decay of apples and pears which seems to be due to an undescribed species of Alternaria. The fungus was first reported at the station in 1902, when it was recognized by W. Paddock, and some inoculation experiments were made in 1904.

So far as studied, the fungus attacks only the fruit of the apple, its most common point of attack being the blossom end. The affected fruits show dark purplish brown, slightly sunken areas at the base of the sepals. This area may remain small and scarcely noticeable for a long time, but when the fruit is placed in storage it is apt to increase in extent until the fruit is entirely decayed. In some cases, although not usually, the blossom end of the apple is cracked open and the adjoining tissue is more or less discolored.

The rotting caused by the fungus is not so rapid as that caused by many of the soft rot fungi, and it seems probable that fruit affected by the Alternaria in many cases succumbs to some of the more rapidly acting rots which seem to follow it.

In many cases there is no noticeable evidence of the presence of the fungus until the apple is cut through, when the core cavity is found to be blackened or discolored. In the majority of such cases the parchment-like lining of the seed cavity is the only part to show the discoloration. This appears brownish or blackened and the seeds are usually covered with a dark colored growth of the mycelium. The invasion of the core by the fungus appears to be most common among certain varieties, the Winesap being especially subject to this form of attack. The reason for this is found in the peculiar structural character of the fruit. Varieties having deep calyx tubes seem to be more subject to this form of attack.

In the case of the pear the fungus has been found on fruit, leaves, and young sprouts. The fruit is liable to be attacked at almost any point. On the leaves the fungus produces brown spots of considerable size.

The microscopic characters of the fungus are described at considerable length, and, although not extensively investigated, it appears from infections that the fungus gains entrance to the fruit through the withered stamens and stigmas which remain at the blossom end of the fruit. The principal source of infection in the spring appears to be diseased fruits, which remain in the orchard, either lying on the ground or sometimes clinging to the fruit spurs. The fungus also hibernates on the twigs and fruit spurs, as was observed during the past season. Wounds in the fruit caused by the larvæ of the codling moth frequently give entrance to the Alternaria.

Numerous cultures have been made of the fungus, and inoculation from these resulted in the formation of decayed areas in 2 or 3 days. The only fruit besides the pear and apple which was inoculated with the fungus was the tomato, but in this case it made no progress.

As previously noted, some varieties of apple are more subject to disease than others, and among the pears the Keiffer is the only one which has shown liability to attack.

No attempt has been made to estimate the amount of injury due to this new rot, but it is not believed to be very destructive as compared with some of the fruit rots which attack the apple and pear in more humid regions.

In the absence of experimental work for the control of the Alternaria rot the author suggests clean culture, the use of fungicides, and the rejection of those varieties which are particularly susceptible to the attacks of the fungus.

California vine or Anaheim disease—its cause and nature, H. HOOPS (*How to make grape culture profitable in California. Wrights, Cal.: Author, 1904, pp. 3–8*).—The author has been making a special study of the California vine disease and claims that its prime cause is the great change in the moisture content of soils from wet in the spring to dry during the latter part of the summer.

If the soils were always wet or always dry there would be no disease. In order to prove this claim the author irrigated vines of susceptible varieties during the early

part of June by soaking the ground thoroughly, after which the water was shut off and the ground became exceedingly dry. Some of the vines showed the attack of disease the first summer, while others did not show it until the second. All vines in the same vineyard that were not irrigated remained healthy.

The author discusses the resistance of varieties to this disease, and suggests combating it by the use of resistant stocks.

Black rot and its treatment, A. PRUNET (*Prog. Agr. et Vit. (Ed. l'Est), 26(1905), No. 17, pp. 509–518*).—It is claimed that by destroying all dried grapes that remain on the vines in the fall and careful attention to the periods when the black-rot fungus appears, it will not be necessary to extensively spray vineyards every season. If these suggestions are rigorously followed over large areas, the author believes that black rot and the destruction it causes could be almost wholly eliminated.

Treatment of mildew, L. DEGRULLY (*Prog. Agr. et Vit. (Ed. l'Est), 26(1905), No. 17, pp. 505–507*).—Formulas are given for the preparation of basic and neutral solutions of Bordeaux mixture and Burgundy mixture, with suggestions for the use of these fungicides in dry and wet regions where mildew alone is to be expected or where black rot also occurs.

The proper application of copper fungicides, L. DEGRULLY (*Prog. Agr. et. Vit. (Ed. l'Est), 26 (1905), No. 16, pp. 477, 478*).—For combating black rot of grapes the author strongly recommends the use of dilute solutions of copper. It is said that 10 hectoliters of Bordeaux mixture containing 1 per cent of copper gives better results than 5 hectoliters of a 2 per cent solution.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The destruction of birds by the elements, 1903–4, E. H. FORBUSH (*Agr. of Mass., 1903, pp. 457–503, pl. 1, figs. 3*).—During 1903, the spring, especially the month of May, was drier than had been reported for Massachusetts for the previous 30 years. This led to a scarcity of water and insects and was followed by extensive forest and grass fires. The month of June following showed an unusual rainfall and cold weather, while the winter of 1903–4 was one of unusual severity. The drought and forest fires of spring combined with the heavy rains and floods of June and the severe weather of winter destroyed the food and the eggs and nests of various species of birds and the adult birds themselves in large numbers.

Detailed notes are given from reports received from correspondents regarding the effects of these severe climatic conditions in destroying birds. Suggestions are made regarding nesting boxes and other means of protecting birds.

The quail, the best insect and weed exterminator, E. HARRIS (*Toronto: W. Briggs, 1905, pp. 11*).—The habits and food of the quail are discussed in considerable detail with especial reference to the value of this bird in destroying injurious insects and weed seeds.

Fruit-eating birds, C. FRENCH, JR. (*Jour. Dept. Agr. Victoria, 3 (1905), No. 5, pp. 364–370*).—Notes are given on the distribution, breeding season, and feeding habits of a considerable number of birds which feed upon fruit in New South Wales.

Report of committee on gypsy moth, insects, and birds, A. PRATT ET AL. (*Agr. of Mass., 1903, pp. 220–225, pl. 1*).—During 1903 climatic conditions were unfavorable to the spread of insects. Numerous complaints were made, however, on the injuries due to gypsy moth. The moth was found present in large numbers in Medford, Malden, and Melrose. Since the pest occurs abundantly along railroads and about depots, it is suggested that railroad transportation may ultimately be responsible for distributing the insect very widely.

Some miscellaneous results of the work of the Bureau of Entomology, VIII (*U. S. Dept. Agr., Bur. Ent. Bul. 54, pp. 99, pls. 4, figs. 20*).—*The sugar cane beetle, E. S. G. Titus* (pp. 7–18).—*Ligyrus rugiceps* injures cane before the tips appear

above ground and about 1 to 2 in. above the base of the stalks. Corn is similarly attacked. The life history of the pest is outlined and notes are given on its enemies. In preventing injury infested fields should not be planted until spring, rubbish should be cleared up, and corn should not follow cane. The pest may be reduced by hand picking.

Report on a Mexican cotton pest, the "conchuela," A. W. Morrill (pp. 18–34).—*Pentatoma ligata* was studied in Durango, Mexico. A technical description of the pest is given, with notes on the food plants. Adults feed on the bolls, stem, and leaves. The number of eggs ranges from 20 to 40 and the period of incubation is about 8 days. The bugs may be hand picked or brushed into pans containing oil.

The sugar-beet crown borer, E. S. G. Titus (pp. 34–40).—*Hulstea undulatella* was found injuring sugar beets in Washington, Oregon, and California. The larvæ tunnel from the base of the leaves down through the root. The insect is described and notes are given on its distribution. The pest may be partly controlled by thorough cultivation of the soil about the time when the larvæ are mature.

The dock false-worm, F. H. Chittenden and E. S. G. Titus (pp. 40–43).—*Taxonus nigrisoma* feeds on dock and sugar beets. The pest may best be controlled by eradicating dock and knotweed in the vicinity of beet fields.

The pepper weevil, C. M. Walker (pp. 43–48).—*Anthonomus æneotinctus* is reported as injuring sweet peppers in Texas since 1903. The peppers become infested immediately after the blossoms fall. The life history of the pest is outlined in considerable detail and notes are given on its feeding habits. Arsenicals are probably of little use against this insect. All infested peppers should be gathered and destroyed.

Cold storage for cowpeas, J. W. T. Duvel (pp. 49–54).—Experiments in combating weevils in cowpeas showed that cowpeas may be kept free from weevils by maintaining them at a temperature of 32–34°. This process does not injure the seed and may be applied for 15 to 25 cts. per bushel per season. The storage room should be kept dry.

The larger canna leaf-roller, F. H. Chittenden (pp. 54–58).—*Calpodes ethlius* attacks canna in South Carolina and Alabama. The pest is described, with notes on its life history and distribution. It may be readily controlled by hand picking from infested leaves.

Grasshopper conditions in Nebraska, northeastern Colorado, Wyoming, Montana, and western Kansas during the summer of 1904, L. Bruner (pp. 60–64).—A brief account is given of injuries due to various species of grasshoppers, including *Melanoplus differentialis, M. bivittatus, M. atlanis, Camnula pellucida*, etc.

The bulletin also includes short articles on *Galerucella nymphææ*, Colorado potato beetle in Great Britain, hydrocyanic-acid gas for cigarette beetle, Fuller's rose beetle, *Castnia licus* in sugar cane, *Rhizobius lophanthæ*, mosquitoes, *Anticarsia gemmatilis*, cabbage worm, *Monocesta coryli*, plum gouger, *Epilachna borealis*, hydrocyanic-acid gas for bed bug, red spider on cotton, etc.

Thirty-fifth annual report of the Entomological Society of Ontario, 1904 (*Ann. Rpt. Ent. Soc. Ontario, 35 (1904), pp. 112, pls. 2, figs. 61*).—At the forty-first annual meeting of the society held at London, Ontario, October 26 and 27, 1904, a number of papers were read and reports submitted, some of which are of sufficient economic importance to be briefly noted in this connection.

Brief reports were made on the insects of the year in different districts of Ontario, attention being called to some of the more conspicuous insect injuries noted during the year. Reports were also received from the various branch societies. Insects and weeds in the Northwest Territory were discussed by T. N. Willing. Box elder was greatly damaged by the larvæ of *Hibernia tiliaria* and quaking aspen by *Clisiocampa fragilis*. The beet webworm was also observed in considerable abundance.

W. Lochhead discussed a number of insect problems. During the season plum and apple curculios were abundant and *Phoxopteris nubeculana* caused considerable

damage to apples. Notes are also given on various garden insects; borers on the hollyhock, Aquilegia, and dahlia; spring-tails in primroses; household pests, bot flies, and other injurious insects. The author made a test of two formulas of lime-sulphur wash, the first containing 25 lbs. lime, 20 lbs. sulphur, and 12½ lbs. sal soda per barrel of water, and the second containing 30 lbs. lime, 15 lbs. sulphur, and 5 lbs. caustic soda per barrel of water. After careful application of these two forms of wash it was found that excellent results were obtained with both and that little difference could be seen in their effectiveness. Attention is also called to the recent progress in entomological study including the importation of parasitic and predaceous enemies, the development of effective insecticides, study of malaria, etc.

The distribution of insects in the Great Basin was discussed by H. F. Wickham, and insects injurious to orchard crops in 1904 were considered by J. Fletcher. The latter called attention to the comparative scarcity of the pea weevil, the attacks of asparagus beetles, cabbage aphis, cutworms, beet-leaf miner, cabbage worms, carrot fly, San José scale, New York plum scale, squash bug, and insects on house plants. The same author briefly reviewed some of the entomological work of 1904.

The report of the society also contains a list of insects captured during the year; notes on basswood insects by A. Gibson, and on the columbine borer (*Papaipema purpurifascia*) by A. Gibson; a list of insects collected at night by J. D. Evans; spinning methods of the polyphemus moth by J. W. Cockle; insect names by J. B. Williams, notes on the insects of 1904 by C. Stevenson; insects affecting the oak and food habits of certain hymenoptera by T. W. Fyles; an elementary study of insects by W. Lochhead, and the pear-tree psylla by G. E. Fisher.

Leaf hoppers and their natural enemies, R. C. L. PERKINS (*Hawaiian Sugar Planters' Sta. Div. Ent. Bul. 1, pts. 5, pp. 159–181, pls. 3; 6, pp. 187–205, pls. 3; 7, pp. 205–238, pls. 4; 8, pp. 239–267, pls. 3*).—Earwigs occasionally do damage to garden plants, hops, etc. Some of these are also insectivorous. Among the eight species of earwigs in Hawaii five have been observed in cane fields and two seem to be of some importance in destroying leaf hoppers. These species are *Chelisoches morio* and *Anisolabis annulipes*. These are described in all their stages. Notes are also given on *Chrysopa microphya*, *Baccha siphanticida*, and *B. monobia*. The last two species belong to the family Syrphidæ and are described as new.

The family Mymaridæ contains a number of parasitic insects which live upon various orders of insects. One of the most important species as a parasite of leaf hoppers is *Paranagrus optabilis*. Various other new species of this family are described, and notes and descriptions are also presented of new species of Proctotrupoidea.

Mention is made of a number of enemies of leaf hoppers found among Orthoptera, Coleoptera, and Hemiptera. The most important predaceous insect discussed is the grasshopper *Xiphidium varipenne*, which is described as a new species. This species is largely insectivorous and feeds during all its stages on various insects. The young grasshoppers were observed catching and eating nymphs of the leaf hoppers. An examination of the stomach contents of these grasshoppers showed that 21 per cent of them contained insect remains. Notes are also given on *X. latifrons*, *Callineda testudinaria*, *Coccinella repanda*, *Verania frenata*, and a number of Hemiptera.

Notes are given on three other families of parasites, Encyrtidæ, Eulophidæ, and Trichogrammidæ. Particular attention is given to the classification of the parasites of these families with descriptions of new genera and species. A brief bibliography is added and a table given of the species discussed.

Combating scale insects, TRABUT (*Bul. Agr. Algérie et Tunisie, 11 (1905), No. 10, pp. 215–217*).—Particular attention is given to the control of scale insects on orange trees. While good results may be obtained by the use of various forms of petroleum emulsions, these remedies are considered difficult to prepare and apply. Lime-sulphur-salt wash is recommended as a reliable insecticide for scale insects on

oranges. Good results have also been obtained from the use of a mixture containing 5 kg. sulphate of iron and 5 kg. lime per 100 liters of water.

May flies and midges of New York, J. G. NEEDHAM, K. J. MORTON, and O. A. JOHANNSEN (*N. Y. State Mus. Bul. 86, pp. 352, pls. 37, figs. 18*).—This constitutes the third report on aquatic insects based on investigations conducted under the direction of the State entomologist.

A special account is presented of the summer food of the bull frog as observed at Saranac Lake. The insect and plant food of the bull frog is classified in a tabular form according to its systematic position. Special notes are also given on the different kinds of food found in the stomach of the frogs examined.

The greater part of the bulletin is occupied with a biological account of Ephemeridæ, Hydroptilidæ, and nematocerous Diptera. The habits and life history of many of the species are considered. Analytical tables are presented for the ready identification of the species and many new species are described. A bibliography relating to the subject is also given.

Report of the entomologist, C. B. SIMPSON (*Transvaal Dept. Agr. Ann. Rpt. 1904, pp. 345–352*).—A brief account is given of the equipment of the entomological department, legislation regarding injurious insects, orchard fumigation, beekeeping, locust destruction, *Novius cardinalis*, and insects injurious to man, plants, and stored products.

The monthly bulletin of the division of zoology, H. A. SURFACE (*Penn. Dept. Agr., Mo. Bul. Div. Zool., 3 (1905), Nos. 2, pp. 33–64; 3, pp. 65–96; 4, pp. 97–128; 5, pp. 129–160, pls. 2, figs. 5*).—Brief discussions are presented of plant lice, cabbage root-worm, scale insects, nursery inspection, flies, fumigation of buildings, fall webworm, preservation of birds, canker worms, Hessian fly, etc. A spraying calendar is also given.

Cooperative spraying experiments, M. V. SLINGERLAND (*New York Cornell Sta. Bul. 235, pp. 81–98, figs. 10*).—A series of cooperative spraying experiments for different purposes have been carried out with various fruit men with the result that while no new discoveries have been thereby secured the experiments have served as object lessons for neighboring fruit growers.

In spraying for plum curculio some of the fruit men reported no beneficial results on account of the fact that the curculio did not appear in large numbers. Others, however, found benefit from the use of arsenate of lead at the rate of 2½ lbs. per 50 gal. of water. Three applications were made, just before blooming, just after the petals fell, and again about a week later. The author recommends that arsenate of lead should be applied at least twice at the rate of 3 or 4 lbs. in 50 gal. of water or in Bordeaux mixture. The New York fruit growers appear to consider it unwise to cultivate cherry orchards late enough to affect the plum curculio. One fruit grower sprayed for the quince curculio at the rate of 2½ lbs. of arsenate of lead per 50 gal. of water. Two applications were made and the results were favorable to the continued use of this method.

Further experiments in spraying for the control of the grape root-worm indicate that this pest may be satisfactorily kept in check when grapevines are sprayed with arsenate of lead at the rate of 8 lbs. per 100 gal. of water. The total expense of spraying is about $3.25 per acre, and an examination of grapevines showed that in many cases the insects were entirely eradicated. The leaves on sprayed vines remained green and healthy long after untreated vineyards began to look brown. It is believed that two applications of arsenate of lead will be necessary, one as soon as the beetles appear and the other about a week or 10 days later.

A comparative test was made in the preparation of Bordeaux mixture from ordinary line and "new process" lime. It appears that some dealers sell air slaked lime for prepared limes. It should be remembered that in order to make a satisfactory Bor-

deaux mixture it is necessary that the lime be capable of combining chemically with the copper sulphate.

One satisfactory method of making Bordeaux mixture was found to be to have three barrels emptying by a faucet into a common trough connecting with the spray tank. In one barrel 15 lbs. of copper sulphate is dissolved in 50 gal. of water, in the second from 18 to 20 lbs. "new process" lime is dissolved in the same manner, while the third barrel is filled with clear water. After the contents of the barrels have been thoroughly agitated all three barrels are opened and the materials flow together into the spray tank. In these experiments it was found that prepared limes cost somewhat more than stone lime but they possess an advantage in that all the material could be used, while this is not true with ordinary stone lime in barrels.

The insect pests of cotton, H. A. BALLOU (*West Indian Bul., 6 (1905), No. 2, pp. 123–129*).—In this article the author discusses the habits, life history, and the medial measures against cotton worm, red maggot, *Eriophyes gossypii*, and other cotton pests.

The cotton red spider, E. S. G. TITUS (*U. S. Dept. Agr., Bur. Ent. Circ. 65, pp. 5, figs. 2*).—*Tetranychus gloveri* causes injury to the cotton plant by feeding chiefly on the underside of the leaves, but occasionally attacks all parts of the plant. While under the leaves the mites are protected by a loose web.

The life history and means of distribution of this pest are briefly indicated. Several species of predaceous insects prey upon the mites and their eggs. The cultural methods of control of the pest include rotation of crops, destruction of cotton stalks, deep plowing, and burning and destruction of weeds and rubbish. For spraying infested plantations the author recommends the use of sulphur, lime-sulphur wash, lye-sulphur wash, or kerosene emulsion.

Insect enemies of tobacco in Hawaii, D. L. VAN DINE (*Hawaii Sta. Bul. 10, pp. 16, figs. 6*).—Notes are given on the habits, life history, and means of combating the more important insect pests of tobacco in Hawaii, including cutworms, tobacco flea beetle, *Phthorimæa operculella*, false budworm, tobacco hornworm, *Adoretus umbrosus*, and cigarette beetle. Notes are given on the occurrence of these pests and remedies suggested which are suited to Hawaiian conditions.

Review of the insect pests affecting sugar cane, H. A. BALLOU (*West Indian Bul., 6 (1905), No. 1, pp. 37–47*).—In this article a concise summary is given of known facts regarding some of the most injurious pests of sugar cane, including *Diatræa saccharalis*, *Sphenophorus sericeus*, *Diaprepes abbreviatus*, *Castnia licus*, and other pests. Recommendations were made regarding the most effective methods for controlling these insects.

The joint-worm, F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Circ. 66, pp. 5, figs. 5*).—This pest occurred in great numbers in 1905, particularly in Indiana and Virginia. The insect is described in its different stages to assist in its recognition. No direct and effective remedies are known. Cultural methods for use in reducing the ravages of the pest include the use of fertilizers, thorough cultivation, burning stubble, and rotation of crops.

The cottony grass scale, EDITH M. PATCH (*Maine Sta. Bul. 121, pp. 169–180, pls. 2*).—The cottony grass scale (*Eriopeltis festucæ*) did not attract much attention until 1904, when it occurred in large numbers and caused extensive injury to grass lands.

It was noticed in 1905 that the insect had spread very rapidly in localities where infestation was observed during the previous year. The number of eggs in each sac is 600 to 700, and under favorable conditions it is apparent that the pest may multiply rapidly. The insect is held in check to some extent by unfavorable weather conditions, the prevalence of rust upon grasses, predaceous insects, overcrowding, and parasites. Since the insect passes the winter in the egg stage attached to grass blades above ground, it is a simple matter to control it by burning infested grass

land. In one instance where this was tested in the spring of 1905 the scale insect was almost entirely destroyed by a single treatment.

Detailed notes are given on the life history of the insect. It seems to attack chiefly June grass and red top. A list is given of the parasites bred from the pest and brief notes are given on the literature relating to this subject.

Control of codling moth, T. W. Kirk (*New Zeal. Dept. Agr., Divs. Biol. and Hort. Bul. 6, pp. 7*).—Tests were made of the efficiency of spraying trees with Paris green, resin solution, a combination of arsenic and soda, arsenate of lead, and kerosene emulsion in the control of codling moth. The amount of clean fruit after the application of these insecticides varies from 81 to 89 per cent.

Descriptions of three species of fruit flies, T. Broun (*New Zeal. Dept. Agr., Divs. Biol. and Hort. Bul. 4, pp. 6, pl. 1*).—The author describes as new with notes on their habits and life history *Tephrites xanthodes*, *Lonchæa splendida*, and *Drosophila ampelophila*.

A mite disease of grapevines, F. Bœuf (*Bul. Agr. Algérie et Tunisie, 11 (1905), No. 10, pp. 217–221*).—Considerable injury has been done to grapevines in Tunis by *Cœpophagus echinopus*. This mite attacks the roots of grapevines and ultimately causes the death of the plants. Ordinarily the pest feeds upon dead wood and detritus, but may attack sick grapevines which have a low resisting power.

The application of bisulphid of carbon to the soil around infested vines has been found to yield excellent results. In some cases single treatment with 300 kg. per hectare was sufficient but, as a rule, 2 treatments requiring 400 kg. per hectare were more satisfactory.

Insects attacking cacao in the West Indies, H. A. Ballou (*West Indian Bul., 6 (1905), No. 1, pp. 94–98*).—Notes are given on the habits, life history, and means of combating a number of insect pests of cacao, including *Steirastoma depressum*, *Physopus rubrocincta*, etc.

The cottony maple scale, J. G. Sanders (*U. S. Dept. Agr., Bur. Ent. Circ. 64, pp. 6, figs. 4*).—The economic importance of the cottony maple scale is discussed with notes on its food plants, habits, life history, parasites, and predaceous enemies.

In some cases the natural enemies of the scale are quite effective in reducing its numbers. Occasionally, however, the pest multiplies to such an extent that artificial remedies must be applied. For this purpose infested trees may be trimmed in the fall and sprayed with kerosene emulsion or whale-oil soap. In the summer a weak kerosene emulsion (not more than 10 or 12 per cent) may be used in cases of excessive infestation.

The bronze birch borer, M. V. Slingerland (*New York Cornell Sta. Bul. 234, pp. 65–78, figs. 9*).—*Agrilus anxius* is reported as having greatly injured or destroyed European white birch on the Cornell campus and elsewhere.

The presence of this insect may be recognized from the hole through which it enters into the bark, by the dying of the top branches of the tree, and by the ridges which develop over the burrows of the insect on the branches. The pest is described in detail with notes on its life history and on previous records of its occurrence. This insect is widely distributed throughout northern United States and Canada. It attacks all kinds of birch trees and occasionally willows.

The bronze birch borer hibernates as a full-grown grub and appears in the spring, after which it lays its eggs probably in the crevices of the bark. There is one brood annually. The pest is preyed upon by woodpeckers and also by at least one parasite, *Phasgonophora sulcata*. There appears to be no way of preventing the borer from laying its eggs upon the birch and the only practical way of checking its ravages is promptly to cut and burn infested trees during the winter or at least by May 1.

Ants, W. W. Froggatt (*Agr. Gaz. N. S. Wales, 16 (1905), No. 9, pp. 861–866, pl. 1*).—The appearance and habits of various species of native Australian ants are

discussed with reference to their economic importance and methods of destroying the injurious species.

Introduction of bees to Australia, A. GALE (*Agr. Gaz. N. S. Wales, 16 (1905), No. 9, pp. 848–852*).—An historical statement is presented regarding the first importations of bees to Australia and the difficulties which the bee raisers experienced in combating foul brood and other diseases of bees.

Bee culture, I. HOPKINS (*New Zeal. Dept. Agr., Dirs. Biol. and Hort. Bul. 5, pp. 30, pls. 5, figs. 2*).—A general account is presented of the use of comb foundation, method of ripening extracted honey, the symptoms and treatment of foul brood, the treatment of bee moth, and the relation of apiculture to various lines of agriculture.

The nutrition of the bee, T. CHERRY (*Jour. Dept. Agr. Victoria, 3 (1905), No. 6, pp. 469–474*).—Attention is called to the importance of proper food for the development of larval bees. The composition of pollen from different plants varies greatly, particularly with regard to the amount of protein. An adequate supply of protein is considered quite necessary to the development of a vigorous colony, and where any doubt is felt regarding the composition of pollen or other bee food a supply of rye flour should be provided. Rye flour is apparently better than wheat flour, which is likely to become caked in a hard mass.

FOODS—HUMAN NUTRITION.

The relation of population to food products, Y. GUYOT (*Le rapport de la population et des subsistances. Nancy: Berger-Levrault & Co., 1905, pp. 24*).—On the basis of statistics, the author discusses meat and wheat production in proportion to the population, and believes that for the last 70 years the production has not kept pace with the increase in population. Intensive agriculture is, therefore, considered a necessity.

The seaweed industries of Japan and the utilization of seaweeds in the United States, H. M. SMITH (*Extr. from Bul. Bur. Fisheries [U. S.], 24 (1904), pp. 133–181, pls. 5, figs. 33*).—A number of marine plants are used in Japan as food, for fertilizer, and in other ways. The character and extent of the seaweed industry is discussed and the different seaweeds described in detail. The author also describes the Irish moss industry of Massachusetts and discusses other seaweeds which are used to a greater or less extent in the United States, and suggests ways in which the use of seaweeds may be increased.

Report of the Commissary-General to the Secretary of War, J. F. WESTON (*Rpt. Commis. Gen. [U. S. Army], 1905, pp. 21*).—In addition to the usual data regarding the resources and expenditures of the Commissary-General, some information is given regarding the army training school for bakers and cooks at Fort Riley, Kans. The testing of flour, rations in the Philippines, and related topics, and tests of methods of cooking without fire are very briefly alluded to.

Food legislation, W. D. BIGELOW (*N. Y. State Libr. Bul. 97, pp. k1–k3*).—In a review of food legislation enacted in 1904 the author states that no general food laws were enacted during the year and that new food laws of even limited scope were few. The modifications of existing laws are briefly spoken of. In the author's opinion they were not sufficiently numerous or sufficiently important in their bearing to call for an extended notice.

Review of the literature of composition, analysis, and adulteration of foods for the year 1904, A. J. J. VANDEVELDE and M. HENSEVAL (*Separate from Bul. Serv. Surveill. Fabric. et Com. Denrées Aliment., 1905, pp. 104*).—In this, the fifth annual volume, titles are reported of articles on analytical methods, apparatus, water, food products, preservatives, spices, and related topics. Notes explaining the char-

acter of the articles cited supplement the bibliographical data in a number of cases. For earlier work see E. S. R., 16, p. 999.

Pure food (*Rpt. Bur. Agr., Labor and Indus. Mont., 9 (1904), pp. 262-272*).—The Montana statutes which relate to pure food are summarized and the fact pointed out that the State has no pure-food law. Some data regarding the extent of adulteration in the State and an article on the importance of milk and meat inspection to the public health by T. J. Sullivan are also included. Sixty-five per cent of the foods and vinegars examined were found to be adulterated or sophisticated.

Food preservatives, their advantages and proper use. The practical versus the theoretical side of the pure-food problem, R. G. ECCLES (*New York: D. Van Nostrand Co., 1905, pp. VI+202*).—The author believes that used in a reasonable way there is less danger from the ordinary food preservatives than from bacteria and other micro-organisms whose growth and development they hinder. The majority of his opinions and deductions favoring the use of preservatives are not in accord with the consensus of opinion of food chemists. The volume contains an introduction by E. W. Duckwall.

Coloring matters for foodstuffs and methods for their detection, W. G. BERRY (*U. S. Dept. Agr., Bur. Chem. Circ. 25, pp. 40*).—The introduction states that this summary of data on the classification and detection of coloring matters, which was presented as a report to the Association of Official Agricultural Chemists, is regarded as preliminary and is published in the hope of eliciting suggestions and criticisms. The classification of colors includes coal-tar color lakes, natural colors of vegetable and animal origin, organic lakes, mineral pigments, and coloring compounds.

The use of coal-tar colors in food products, H. LIEBER (*New York: H. Lieber & Co., 1904, pp. 150; rev. in Jour. Amer. Chem. Soc., 27 (1905), No. 10, p. 1364*).—The main portion of this volume is taken up with an account of physiological experiments with dogs and rabbits on the effects of coal-tar colors given hypodermically and in food. It is apparently very largely a translation of T. Weyl's *Die Theerfarben.*

A summary is also given of the laws of different countries relating to the use of coal-tar colors in foods. The author urges that dealers in colors intended for food products be forced to sell only colors which have been demonstrated to be harmless and that manufacturers of food products should exercise more care in selecting colors.

The composition of West Indian foods as shown by analyses made in the laboratory of the Colonial Museum at Haarlem, M. GRESHOFF ET AL. (*Bul. Kolon. Mus. Haarlem, 1904, No. 30, Sup.; 1905, No. 33, Sup.*).—Continuing earlier work (E. S. R., 15, p. 495) analyses are reported of 150 food products obtained from Suriname and Curaçao.

Some of the materials analysed were corn meal of local production, rice, yams, taro, yautia or tannia, banana flour, breadfruit flour, colocasia flour, cactus flour made from the stems of a variety of Cereus, cassava, breadfruit, mango, passion flower fruit, mammea, guava, papaya, spondia, memordica, banana, pineapple, rose apple (*Eugenia jambosa*), sapodilla, tamarinds, beans, peanuts, carcoyar nut, and various other fruits and nuts, as well as vegetables, meat, fish, etc.

Analyses of some Martinique food plants, P. AMMANN (*Agr. Prat. Pays Chauds, 5 (1905), No. 32, pp. 439, 440*).—Analyses of several samples of yautia and yam are reported.

The value of wheat for bread-making purposes. Experiments and analyses, F. F. BRUYNING, Jr. (*Separate from Arch. Teyler, 2. ser., 9 (1905), pt. 3-4, pp. 217, pls. 4*).—An extended series of investigations is reported on the composition and bread-making value of a number of varieties of wheat of special importance in the Low Countries. The experimental and analytical methods followed are described and a large amount of data is summarized regarding the work of other investigators.

A study of durum wheat, F. A. NORTON (*Jour. Amer. Chem. Soc., 27 (1905), No. 8, pp. 922–934*).—The investigations reported with durum wheat were carried on at the South Dakota Station, and the results have been in part noted from another publication (E. S. R., 17, p. 269).

Durum wheat products are noticeably sweet. Analyses showed that Kubanka durum wheat contained 3.26 per cent sugar and Blue Stem 1.42 per cent, invert sugar and soluble starch being absent in both wheats. Approximately 1.25 per cent dextrin was also found in the Kubanka wheat.

In the discussion on macaroni making the author states, on the basis of personal observation, that most of the American macaroni is made from bread wheat, yet he is convinced that the durum wheats are greatly superior for the manufacture of macaroni and other edible pastes. He also considers durum wheats well adapted for the manufacture of breakfast foods.

"Of the different varieties which have been employed for trial at the South Dakota Experiment Station and Highmore substation, Kubanka, Pererodka, Beloturka, Arnautka, and Yellow Gharnovka have given considerably the best results."

The nutritive value of different sorts of flour, P. FAUVEL (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), pp. 1424–1427*).—The experiments with man reported were made with white flour, whole-wheat flour, and brown army bread.

The whole-wheat flour bread did not offer any advantage over the brown bread. It did not furnish more digestible phosphoric acid, while it diminished the excretion of urea, produced an appreciable quantity of purin, irritated the intestine, and diminished the assimilation of other nutrients. The army bread gave better results than the white bread.

The assimilation of whole-wheat bread, P. FAUVEL (*Compt. Rend. Soc. Biol. [Paris], 60 (1906), No. 5, pp. 252–254*).—Continuing work noted above the author studied the comparative value of whole wheat and white bread. In spite of its high protein content the whole-wheat bread caused a diminution of the urea excreted amounting to 2.4 gm. per day on an average, while it increased the excretion of xantho bodies and uric acid and the proportion of these bodies to urea. Although whole-wheat bread contains a large amount of phosphoric acid it did not increase the urinary excretion of this constituent.

The formation of acid in mixtures of flour and water under the influence of bran, G. GEISENDÖRFER (*Inaug. Diss., Univ. Würzburg, 1904; abs. in Hyg. Rundschau, 15 (1905), No. 20, p. 1054*).—Mixed with water rye flour becomes more acid than wheat flour and coarse flour more acid than fine. When mixed with water under similar conditions more acid is formed from bran than from flour and from flour containing bran than from flour without it. In this acid formation the phosphorus compounds in the bran are of importance and very probably the bacteria which are also present.

Testing wheat flour for commercial purposes, H. SNYDER (*Jour. Amer. Chem. Soc., 27 (1905), No. 9, pp. 1068–1074*).—Physical and chemical tests, it is the author's belief, should both be used in testing the quality of wheat flour. For another discussion of this topic by the author see E. S. R., 17, p. 113.

The use of talc as a coating or polishing material for pearl barley, rice, millet, and dried peas, H. MATTHES and F. MÜLLER (*Ztschr. Öffentl. Chem., 11 (1905), pp. 76–82; abs. in Analyst, 30 (1905), No. 351, p. 206*).—Of 25 samples of pearl barley examined, 16 were free from talc, 5 contained less than 0.2 per cent, and the remainder 0.2 to 0.63 per cent.

It was found that by shaking the grains with talc more than 2 per cent would adhere to the barley. The presence of talc can be detected by shaking the grains of barley with water, allowing the mixture to settle, and examining under a microscope. The amount present may be ascertained by igniting 25 gm. of the grain,

extracting the ash with hydrochloric acid to remove magnesium compounds, etc., naturally present, and analyzing the residue. Talc was also found in a number of samples of rice, millet, and peas.

A soy bean bread containing no starch, BARDET (*Bul. Gén. Thér. Méd. et Chirurg., 149 (1905), p. 181; abs. in Biochem. Centbl., 3 (1905), No. 19-20, p. 642*).—An analysis of a soy bean bread is reported.

Studies of canned meat, E. CARLINFANTI and A. MANETTI (*Arch. Farmacol. Sper. e Sci. Aff., 4 (1905), No. 7-8, pp. 345-358*).—Detailed analyses of new and old samples of canned meat are reported and discussed. The preserved meat was provided by the Italian minister of war.

Liebig's meat extract, I. F. KUTSCHER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 9, pp. 528-537; Zentbl. Physiol., 19 (1905), No. 15, pp. 504-508*).—According to the author's conclusions meat extract does not have a uniform composition, and bodies which are occasionally found in it should not be considered as necessary constituents of muscular tissue. The bodies which he identified were ignotin, methylguanidin, carnomuscarin, neosin, novain, and oblitin.

Chinese duck egg yolk, H. LÜHRIG (*Ber. Chem. Untersuch. Amt. Chemnitz, 1904, p. 20; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 4, pp. 255, 256*).—Chinese duck egg yolk alone and mixed with the yolk of hens' eggs is imported into Europe in large quantities for use in the manufacture of noodles and other egg pastes. A sample of such duck egg yolk which the author examined contained 7.18 per cent fat and 1.285 per cent total phosphoric acid, of which 0.906 gm. was soluble in boiling alcohol and 0.379 gm. insoluble.

The spoiling of eggs, H. SCHLEGEL (*Ber. Untersuch. Anst. Nurnberg, 1904, pp. 9, 10; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 4, p. 255*).—It was found that good eggs did not spoil or "rot" when kept in intimate c tact with rotten eggs for 8 days at a temperature of 25° C. They did, however, take up the offensive smell of the spoiled eggs. This investigation was undertaken to determine the possibility of fresh eggs spoiling quickly when contaminated with rotten eggs.

Studies of spoiled canned vegetables, J. BELSER (*Arch. Hyg., 54 (1905), No. 2, pp. 107-148*).—The results of bacteriological studies of spoiled canned goods, of the chemical composition of the gas present in swelled cans, the gas pressure in such cans, the temperature required for sterilization, and related topics with special reference to improvement in methods of canning.

Hop sprouts as vegetables, G. W. ROOSEVELT (*Mo. Consular Rpts. [U. S.], 1905, No. 297, p. 59*).—The author states that young tender hop sprouts are sold in the Brussels markets in large quantities in the spring. Large quantities are also canned or bottled. For the early market, hop sprouts are forced but are not considered as tender and succulent as sprouts cut from plants which have been covered with earth during the winter.

To what constituent does coffee owe its stimulating properties? M. GEISER (*Arch. Expt. Path. u. Pharmakol., 53 (1904), No. 2, p. 112; abs. in Zentbl. Physiol., 19 (1905), No. 15, p. 517*).—According to the investigations reported, coffee owes its stimulating properties solely to the caffein present.

The composition of Java cane-sugar molasses, H. C. PRINSEN GEERLIGS (*Meded. Proefstat. Suikerriet West-Java, 1905, No. 85, pp. 42*).—Analyses of 77 samples of cane-sugar molasses of various sorts are reported and discussed with special reference to the comparative merits of different methods of sugar making. The author notes that centrifugal and drip molasses have practically the same average composition, and that in general the composition of the molasses is determined by that of the sirup before crystallization.

The adulteration of maple products, H. W. WILEY (*U. S. Dept. Agr., Bur. Forestry Bul. 59, pp. 47-54*).—The author points out that glucose is the chief adulterant of maple sugar, and that its use is fraudulent rather than harmful, since

glucose is known to be a wholesome product. The characteristics of pure and adulterated maple products are discussed and standards quoted.

Attention is drawn to the fact that the exact chemical nature of the flavoring material present in the maple products is not known, "though it is probably an ether or aldehyde possessing a high boiling point. . . . Detection of this flavoring matter by chemical means has, up to the present time, baffled the skill of the chemist, and for this reason the taste of the expert has been relied upon almost solely to distinguish between the genuine and the adulterated article in cases where the adulterant is cane sugar. Thus it is apparent that pure cane sugar can be utilized to a certain extent in the adulteration of maple products without certainty of detection.

"The flavoring matters appear to reside chiefly in the molasses or semiliquid parts of the maple product, and for this reason the refining of maple sugar to a perfectly dry, white, crystalline mass would deprive it of the chief of its properties upon which its high market value depends." The use of hickory extract for flavoring artificial or adulterated maple products is spoken of.

Maple sirup and sugar, T. MACFARLANE (*Lab. Inland Rev. Dept.* [*Canada*] *Bul. 102, pp. 18*).—Only 24.3 per cent of samples of maple sugar and sirup, collected before the maple-sugar season in 1905, were found to be genuine. In the case of samples collected after the maple-sugar season 63.4 per cent were found to be genuine.

Concerning the dextrin found in honey from Coniferæ, P. WOLFF (*Inaug. Diss., München, 1904; abs. in Zentbl. Stoffwechsel u. Verdau. Krank., 6* (*1905*), *No. 21, p. 495*).—The author concludes that the dextrin of coniferous honey is not a mixture of dextrin and sugar, but a definite body having the character of achroodextrin and that it differs in the honey from different varieties of Coniferæ. Malic acid, in his opinion, must be regarded as a normal characteristic of natural honey.

Laboratory experiments on the digestibility of dried milk, D. SOMMERVILLE (*Pub. Health* [*London*], *18* (*1905*), *No. 1, pp. 40–45*).—From artificial digestion experiments with dried milk the author concludes that with respect to both protein and fat it is more digestible than fresh milk, the investigation being undertaken with special reference to the use of dried milk in infant feeding.

Dried milk, "in respect of its reaction to rennet, to peptic digestion, to pancreatic digestion, and in respect of the condition of its fat, . . . approaches more nearly to human milk than does fresh milk, if the . . . experiments [reported] convey any truthful information; and, although they must considerably differ from the corresponding natural digestions, still they possess a certain value when carried out . . . [in connection with suitable tests for purposes of comparison]. . . .

"Probably the chief reason for the difference in the tolerance of the 2 forms of fat [cream and butter] is, that in cream the fat is present in the form of globules of neutral fat, which have to be split into glycerin and fatty acids to prepare the fat for absorption. Butter, on the other hand, containing, as it does, nearly 7 per cent of fatty acids—butyric, caproic, etc.—is already partially prepared for absorption. The absorption of butter fat is therefore more rapid and complete than the absorption of cream fat. These differences have their application in the feeding of both dyspeptic adults and children.

"Where it is necessary to add fat in quantity to a diet, it is better perhaps, in most cases, to serve it in the form of butter than to add large quantities of cream to milk, as is so often done, since the retarding influence of cream on the secretion of gastric juice will interfere with the digestion of the proteids of the milk." It is also pointed out that the dried-milk preparation possesses the advantage of sterility and constant composition.

The importance of inorganic salts in the metabolism of man and animals, A. HIRSCHLER and P. TERRAY (*Math. u. Naturw. Ber. Ungarn, 20* (*1902*), *pp. 145–238*).—In this report, published in 1905, the authors hold that increasing knowledge

of the physiology and pathology of cell life emphasizes the importance of the mineral constituents in general and of the phosphates and other phosphorus compounds in particular. Previous work upon the metabolism of phosphorus, calcium, and magnesium is reviewed in some detail, the estimates of different writers as to the amounts of these elements contained in the food and eliminated by the kidneys and the intestines being given.

Experiments upon 2 growing dogs showed that the normal storage of nitrogen during growth was accompanied by a storage of phosphorus and calcium, and that the storage of nitrogen and rate of growth were increased by feeding eggs in place of a part of the ordinary food. This is held to substantiate the view that eggs should be added to the diet of children at as early an age as possible.

Observations upon the metabolism of nitrogen, phosphorus, calcium, and magnesium in a case of *Endoarteritis chronica deformans* are also recorded.

The liberation of energy in fasting and fed animals as shown by the respiratory quotient, A. CHAUVEAU (*Ann. Sci. Agron., 2. ser., 10 (1905), I, No. 2, pp. 191–208*).—The investigations reported led the author to conclude that energy is more slowly liberated in the body when fasting than when fed.

A study of the metabolism of a vegetarian, J. M. SWAN (*Amer. Jour. Med. Sci., 129 (1905), pp. 1059–1065; abs. in Jour. Amer. Chem. Soc., 27 (1905), No. 8, Rev., p. 482*).—On a vegetarian diet the nitrogen consumption was 9.3 gm. per day and the amount excreted in the urine 9.8 gm. The conclusion was reached that the diet followed was not calculated to produce a properly nourished and mentally and bodily active individual.

The influence of the temperature of food upon the stomach, J. MUELLER (*Ztschr. Diätet. u. Phys. Ther., 8 (1905), No. 11; abs. in Brit. Med. Jour., 1905, No. 2339, Epit., pp. 67, 68*).—A series of experiments were undertaken to ascertain to what extent the stomach secretions, its motility, and power of resorption are affected by the temperature at which food is taken. Under ordinary circumstances the temperature of food as eaten varies from 5 to 60° C.

The principal conclusions reached were that the stomach has the power of modifying the temperature of ingested food so that it is equal to that of the body. This change of temperature is effected by the withdrawal of heat in the case of hot foods or raising the temperature in the case of cold foods, and also by the action of the secretions of the stomach. The stomach is emptied more rapidly when the fluid taken has the same temperature as the body. Cold drinks which contain alcohol cause an active secretion by the stomach, while water alone has no such effect.

Relation of creatinin excretion to variations in diet, W. KOCH (*Amer. Jour. Physiol., 15 (1905), No. 1, pp. 15–29*).—In connection with an investigation of the excretion of creatinin the effect of lecithin and kephalin in the diet was studied with man and a dog.

The author calculates that a molecule of lecithin would supply methyl groups for 3 molecules of creatinin, or approximately 8 gm. of lecithin would yield 3.39 gm. of creatinin and that 1 molecule of kephalin would supply its 1 methyl group for the formation of 1 molecule of creatinin, or 8 gm. of kephalin would yield approximately 1.13 gm. of creatinin. The deductions which were drawn follow:

"Creatinin is excreted with remarkable constancy by the dog as well as by man. The extreme daily variations in the case of the dog do not affect the final average. The excretion per kilo body weight for 24 hours is very nearly the same for both (24–26 mg. for the dog; 26–30 mg. for man).

"Under ordinary conditions of diet, the methyl groups of the lecithin and kephalin ingested can all be accounted for by the methyl groups of the creatinin excreted. With an excess of lecithin and kephalin this is not the case, although the creatinin undeniably increased. This increase is due to the lecithin and kephalin of the and not to some other constituent.

"Creatinin is probably a better index of methyl metabolism than of the lecithin and kephalin metabolized, although under ordinary conditions the two seem closely related.

"Further experiments will have to determine if physiological activity is capable of influencing this metabolism to a greater extent than the presence of an excess of methyl groups in the form of lecithin and kephalin.

"If creatinin bears the relation to methyl metabolism suggested in the above paper, it should be possible to demonstrate the presence of creatin in every tissue having such a metabolism. The presence of creatin in striated muscle is a well-known fact. I have also found it in the heart muscle and in the testicle, and am continuing the investigation of other tissues."

The peptic cleavage products of the wheat proteid artolin, H. Hayashi (*Arch. Expt. Path. u. Pharmakol., 52 (1904), p. 289; abs. in Biochem. Centbl., 3 (1905), No. 19–20, pp. 599, 600*).—Gentle digestion gave 2 artroses and on further action of the ferment the artroses yielded parartrose and metartrose. By still further action of the ferment the metartrose was unchanged while the parartrose yielded heteroartrose, protoartrose, and deuteroartrose, as well as artolin antipeptone, a body free from sulphur.

Experiments on carbon-dioxid production when lying down and standing up, K. E. Widlund (*Skand. Arch. Physiol., 17 (1905), No. 3–5, pp. 290–293*).—The experiments reported led to the conclusion that when standing with the muscles relaxed there is no increase in carbon-dioxid production, and hence the amount of muscular effort put forth is very small. When, however, the subject stands with tense muscles there is a relatively large increase in carbon-dioxid production, indicating that thus maintaining the position involves considerable muscular work.

The constant presence, the quantity, and origin of uric acid in the feces of man in health, F. Galdi (*Policlin., Sez. Med., 12, No. 3–4; abs. in Zentbl. Stoffwechsel u. Verdau. Krank., 6 (1905), No. 19, p. 445*).—According to the author, uric acid is a constant constituent of the feces of man in health, the amount being independent of the quantity and weight of the feces. Part of this uric acid comes from the nuclei of lymph cells, part from the blood and from cell nuclei taken in with the food, and a part from the intestinal secretions.

ANIMAL PRODUCTION.

Dried beets as a sugar-yielding feeding stuff, A. Muntz and A. C. Girard (*Ann. Sci. Agron., 2. ser., 10 (1905), I, Nos. 1, pp. 154–160; 2, pp. 161–190*).—Data on sugar and sugar-yielding materials with special reference to sugar beets and sugar-beet products and on apparatus and methods for drying sugar beets are summarized, and studies are reported on the composition of dried beets and their value as a feeding stuff for horses.

When used as a substitute for mixed grain in amounts up to 3.6 kg. per head per day satisfactory results were obtained as shown by a comparison with the gains made by horses fed a standard ration of mixed grain and hay. In the authors' opinion, the sugar-beet industry may be profitably extended by the utilization of this crop as a feeding stuff.

Feeding stuffs, F. T. Holbrook and E. J. Russell (*Jour. Southeast. Agr. Col. Wye, 1905, No. 14, pp. 169, 170*).—Miscellaneous feeding stuffs, including oil cakes, dried grains, oat offal, boiled cabbage stalks, and molascuit were analyzed.

The percentage composition of boiled cabbage stalks was water 84.4, protein 4.1, crude fiber 2.7, and sand 0.7 per cent. "These had been prepared on the erroneous idea that boiling an indigestible body will make it digestible. Boiling may soften the food and reduce the work of the teeth, but it does not enable the digestive fluids to act more vigorously on the boiled than on the unboiled substances."

The oil content of cotton seed of different sorts grown in Central Asia, D. TSCHERNEWSKY (*Zhur. Russ. Fiz. Khim. Obshch., 34 (1902), pp. 503, 504; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 9, p. 561*).—The seed of American cotton examined contained 23.46 per cent oil; the American upland seed, 21.19 per cent; Egyptian seed, 23.35 per cent; Bokhara seed, sample No. 1, 17.15 per cent, and sample No. 2, 17.75 per cent.

Profitable stock feeding, H. R. SMITH (*Lincoln, Nebr.: Author, 1906, pp. XII+413, figs. 71*).—The author has summarized and discussed a large amount of data regarding the feeding, care, and management of farm animals, the results of experiment station investigations having been drawn upon, as well as the experience of practical stock raisers.

It has been the author's purpose to present the results of investigations and experience in such a way that they may be of use to the student and investigator, as well as to the stock raiser, and with this end in view he has summarized and discussed the data rather than cited individual experiments. As a whole, the volume constitutes a useful summary of the general principles of stock raising, milk production, and the feeding, care, and management of beef cattle, sheep, pigs, farm poultry, and horses. The section on poultry was contributed by Miss M. L. Smith.

Steer-feeding experiment, VII, 1903-4, O. ERF, R. J. KINZER, and G. C. WHEELER (*Kansas Sta. Bul. 130, pp. 7, figs. 2*).—A comparison of alfalfa hay alone and supplemented by other coarse fodders (prairie hay, corn silage, Kafir corn stover, and sorghum stover) was made with 2 lots of 10 steers each, the coarse feed being fed in addition to like grain rations.

On alfalfa hay alone the average daily gain per steer in the 143 days of the test was 2.83 lbs. and on alfalfa hay and other coarse fodder, 2.32 lbs, the cost of feed per pound of gain in the 2 cases being 5.28 cts. and 6.69 cts., respectively. The steers fed the alfalfa hay required 4.55 lbs. of coarse fodder and 5.78 lbs. of grain per pound of gain, and those fed alfalfa hay and other coarse fodder, 7.43 lbs. and 7.15 lbs., respectively.

The calculated profit in the case of the lot fed alfalfa hay was $5.85, and with the other lot $2.12. "The profit in either case was very small; indeed, so small as to hardly warrant steer feeding except as a means of marketing the feed of the farm. Alfalfa hay and corn-and-cob meal form a most excellent ration for fattening, and unless future experiments change these results, we shall have to admit that this combination gives better results than the use of a greater variety of roughage."

Methods of steer feeding. Barn v. shed—third trial, T. I. MAIRS and N. G. MILLER (*Pennsylvania Sta. Bul. 74, pp. 8*).—Continuing earlier work (E. S. R., 16, p. 398) the relative merits of feeding in sheds and barns was tested with 2 lots of 12 steers each.

The test began November 4 and closed March 7, the first 4 weeks being regarded as preliminary. In the test proper the average gain made with steers in barns was 127.1 lbs. and by those in sheds 127.6 lbs. Considering both the test proper and the preliminary period the values were 174.5 lbs. and 174.2 lbs. During the test proper the steers in barns consumed 18.67 lbs. of feed per pound of gain at a cost of 12.58 cts. Similar values for the steers fed in sheds were 18.42 lbs. and 12.40 cts. The conclusions drawn from the test were in effect as follows:

The general result of this experiment is at variance with those of the 2 preceding ones in the fact that the steers outdoors ate less food per pound of gain than the ones inside. It confirms the results of earlier work in that the actual amount of food eaten by the outside lot was less than that eaten by the inside lot, and that the gains made by fattening steers are not increased by warm quarters. It is not possible to have stables too cold for fattening steers in this climate, provided they are kept dry and well bedded. It is possible to keep open yards from becoming excessively muddy by the use of soft-coal cinders. A shed in a well-drained yard can be kept

practically as dry as the interior of a barn, provided plenty of bedding is used and the manure is removed sufficiently often.

Summarizing the 3 years' work, the average daily gain of the steers fed in barns was 1.94 lbs. and those fed in sheds 1.82 lbs.

Feeding trials, M. J. R. DUNSTAN (*Jour. Southeast. Agr. Col. Wye, 1905, No. 14, pp. 13–16*).—In the test of the relative merits of Aberdeen Angus, Galloway, Blue Grey, and Red Poll steers the greatest gain, 2.09 lbs. per day, was made by Blue Greys for 164 days and the smallest gain, 1.7 lbs. per day, by Red Polls for 88 days. As regards profits the Galloways ranked first.

Calf rearing, M. J. R. DUNSTAN (*Jour. Southeast. Agr. Col. Wye, 1905, No. 14, pp. 16–18*).—Brief notes are given on different substitutes for milk fat in calf feeding. In 112 days calves fed whole milk gained 1.5 lbs. per head per day as compared with 1.07 lbs. with those fed separator skim milk and cod-liver oil. About 4 oz. was found to be the maximum amount of oil which could be fed. A feed relished by calves was made up of oatmeal, ground linseed meal, linseed cake, and lentils 8:5:3:4, cooked overnight with a small quantity of salt and molasses and fed warm in the proportion of 3 lbs. of meal to 5 qts. of water.

Crossbred sheep, T. R. ROBINSON (*Jour. Southeast. Agr. Col. Wye, 1905, No. 14, pp. 21, 22, figs. 5*).—Hampshire, Kent, Suffolk, and Southdown sheep were used in the crossbreeding tests reported. Judging from the weights recorded the Hampshire-Kent, the Southdown-Suffolk, and the Suffolk-Kent crosses gave the best returns. The Hampshire-Kent lambs sold for the highest price. More twins were dropped by the Suffolk-Kents than by any of the other crosses.

Shearing lambs, M. J. R. DUNSTAN (*Jour. Southeast. Agr. Col. Wye, 1905, No. 14, p. 18*).—In a test of the merits of the practice of shearing lambs, it was found that a lot of 5 shorn lambs gained 58.2 lbs. in 36 weeks as compared with 72.8 lbs. in the case of a similar lot which had not been shorn at the beginning of the trial. The fleece of these lambs weighed 12 lbs. as compared with 7 lbs. in the case of the lambs shorn at the beginning of the trial. Definite conclusions were not drawn.

Maltese goats, J. H. GROUT (*Mo. Consular and Trade Rpts.* [*U. S.*], *1905, No. 298, pp. 105, 106*).—It is stated that there are about 12,000 goats in Malta, both long-haired and short-haired varieties being kept. The milk is considered of very superior quality and is used for table and cooking purposes, but not for the manufacture of butter and cheese. For these products sheep's milk is used. The law requires that goats slaughtered for market shall be at least a month old and shall weigh not less than 12 lbs. The average price of a fair Maltese goat is $15, though some of exceptional merit bring more. Other points connected with the Maltese goat industry are discussed.

The successful type of horse that may be profitably raised by New England farmers, H. W. SMITH (*Agr. of Mass., 1903, pp. 111–144*).—From a consideration of historical and other data, as well as existing conditions, the conclusion was reached that heavy harness horses are the best type for New England farmers to breed. The paper was followed by a discussion.

The influence of radium bromid on metabolism in dogs, W. N. BERG and W. H. WALKER (*Proc. Soc. Expt. Biol. and Med., 2 (1905), p. 89; abs. in Jour. Amer. Chem. Soc., 27 (1905), No. 12, Rev., p. 667*).—When radium bromid was fed to dogs in nitrogen equilibrium it was found that protein metabolism was not materially affected. The total sulphate in the urine was markedly increased.

An improved cage for metabolism experiments, W. J. GIES (*Amer. Jour. Physiol., 14 (1905), No. 5, pp. 402–412, figs. 4*).—A cage is described for use in metabolism experiments with dogs especially.

The farmer's poultry house, F. W. HODSON and F. C. ELFORD (*Canada Dept. Agr., Poultry Div. Bul. 8, pp. 15, figs. 22*).—Poultry houses which have given good satisfaction, constructed by the Canada Department of Agriculture, the Canadian

Poultry and Produce Co., the Truro (N. S.) Agricultural College, and by private individuals, are described and plans given. In these houses several points were specially sought—warm roosting pens, plenty of sunlight, fresh air without drafts, and convenience in cleaning. According to the authors the houses may be built with or without foundations.

"A cement or stone wall sufficiently underground to exclude rats and vermin is an advantage. The cost varies according to the price of lumber and help. The floor in most cases is the soil, though cement or wooden floors will give good satisfaction. . . . In calculating the number of fowls these buildings will accommodate, allow 6 to 8 sq. ft. of floor surface for each breeding fowl and give them from 5 to 10 times as much yard space. For each pen one male will be found sufficient, but it is sometimes advisable to change the male if not specially mated."

On the relative efficiency of poultry houses with and without ground ventilation, T. R. Robinson and E. J. Russell (*Jour. Southeast. Agr. Col. Wye, 1905, No. 14, pp. 175–186, fig. 1, dgms. 2*).—The experiments reported show that poultry houses without floors are not as satisfactory as those with floors, at any rate during the winter, notwithstanding the fact that from studies previously reported (E. S. R., 16, p. 588) the unfloored houses were found to be twice as efficient from the point of ventilation.

It was found that birds raised in floorless houses laid fewer eggs than the others, the difference in the value of eggs produced amounting to 25 cts. per bird for a period of 15 weeks. The temperature of the two houses and the carbon-dioxid content of the air was the same, so in the authors' opinion the reason for the differences observed was neither the purity nor the temperature of the air.

"The quantity of heat lost by the birds in the raised floorless house is, however, greater than in the other; more of their food is consequently required for fuel purposes, leaving less for other requirements. It appears to us that this is the reason of the superiority of the house with a floor.

"Poultry houses cost so little relative to the return they give that it is hardly worth while trying to overcome the difficulty. The simplest plan is to increase the accommodation for the birds, giving each one 10 cu. ft. of air space. Floors, either of wood or brick can then be put in.

"The above conclusions apply in their entirety to movable houses on wheels. If raised above the ground, they become floorless houses, placed on the ground they behave like houses with floors.

"It is absolutely essential to secure top ventilation. The houses received by us from the makers have usually been deficient in this respect, and we have had to bore holes in the eaves. By doing this we reduced the amount of carbonic acid in the air from 30 to 9 parts in 10,000 volumes, and effected an improvement in the eggs."

A practical poultry plant for southern California, E. P. Mitchell (*Los Angeles, Cal.: Out West Pub. Co., 1904, pp. 105, pls. 6, figs. 34, chart 1*).—In the author's opinion, the poultry industry in southern California is capable of great development and on the basis of experience he discusses such topics as buildings, hatching, brooders, houses, feed, water supply, and expenses for equipping a poultry plant with special reference to local conditions.

The poultry, T. R. Robinson (*Jour. Southeast. Agr. Col. Wye, 1905, No. 14, p. 25*).—Brief notes are given regarding the station poultry flock and cross-breeding experiments which have been undertaken. From White Minorcas crossed with Black Court-pattes a strain has been developed which it is proposed to call the White Crowns. These are distinguished by white plumage, short white shanks, and a long breast bone. They lay large white eggs, feather early as chickens, and make very fair table poultry.

The adaptability of concentrated by-products for poultry feeding, W. P. Wheeler (*New York State Sta. Bul. 271, pp. 387–403*).—The tests reported were made

with chickens and ducklings to study the comparative value of a number of concentrated feeds for supplying protein and mineral matter, constituents which the ordinary ration does not supply in sufficient quantity at times.

In the test with ducklings 3 lots containing 30 birds each at the beginning were fed during the period of most rapid growth rations in which 60 per cent or more of the protein was derived from by-products of animal origin. Except for a small amount of blood meal included in the grain mixture fed each lot the nitrogenous feeds were for lot 1, animal meal and meat meal; for lot 2, blood meal and bone meal; and for lot 3, milk albumin (a by-product from milk sugar factories) and bone meal. The average gain in weight per fowl for the 9 weeks of the test was 82.2 oz. on animal meal and meat meal, 67.7 oz. on blood meal and bone meal, 81 oz. on milk albumin and bone meal, the cost of a pound of gain in the 3 cases being 4.8, 5.7, and 6.1 cts.

In the test with chickens, which was made with 4 lots containing from 43 to 50 chicks 2 weeks old at the beginning of the trial, 2 of the lots were fed rations in which most of the protein was derived from highly nitrogenous animal by-products, namely, animal meal and milk albumin. Of the remaining 2 lots one received added protein in the form of gluten meal and the other gluten meal with a little bone meal. As a basal ration all lots were fed cracked corn, wheat, green alfalfa, and a grain mixture. In the 8 weeks of the test the average gains per bird were 12.9 oz. on animal meal, 11.5 oz. on milk albumin, 4.6 oz. on gluten meal, and 9 oz. on gluten meal and bone meal, the cost of a pound of gain ranging from 6.4 cts. on the last mentioned ration to 14.6 cts. on gluten meal.

The author's conclusions were in effect as follows: Of three highly nitrogenous rations fed to ducklings, the one containing dried blood and bone meal was associated with much slower growth than the one containing animal meal and that containing milk albumin and bone meal, though the same amount of food under each ration gave equal increase in weight. The superiority of the two rations mentioned seemed due chiefly to their greater palatability.

Of four rations carrying much concentrated food the one containing a large proportion of gluten meals proved inferior, when fed to young chicks, to that having bone meal in addition to gluten meal, and much inferior to others in which most of the gluten meal was replaced by animal meal or by milk albumin. Unpalatability seemed largely responsible for the inferiority of the two rations. The ration giving the poorest results was also deficient in mineral matter.

The rations containing milk albumin were more palatable and seemed more healthful than the others, but owing to the higher price of this food it was not profitably used in the desired quantity. The rations containing animal meal were more profitably fed.

The results and observations in general, like those from other trials, show a greater disadvantage in the free use of foods of uncertain palatability and healthfulness during earlier stages of growth than at any other time. The composition of the feeding stuffs used is reported.

Feeding cotton-seed meal to chickens (*Rel. Poultry Jour., 12 (1905), No. 8, p. 836*).—Cotton-seed meal if fed to poultry should, it is said, be fed separately. A ration of equal parts by weight of corn meal and wheat bran, with sufficient low-grade flour and middlings to roll into a ball and at the same time not be sticky, can be used with the cotton-seed meal, the latter constituting about 10 per cent of the whole mash.

Growth of chickens and cost of rearing, E. BROWN (*Jour. Bd. Agr. [London], 12 (1905), No. 5, pp. 257-272; reprinted by Univ. Col. Reading, Agr. Dept., 1905, pp. 16*).—To secure data regarding the growth of chickens and the cost of rearing, a test was made with White Wyandottes, Faverolles, Buff Orpingtons, and crossbreds.

The different lots each contained 29 or 30 birds and all received uniform treatment. When 13 weeks old the average weight of the chickens ranged from 1 lb. 14 oz. each

with the crossbred birds to 2 lbs. 3 oz. with the Buff Orpingtons, and the average cost per bird, including the original cost of egg and incubator and brooder expenses, ranged from 15.42 cts. with the crossbred birds to 17.32 cts. with the White Wyandottes. The cost of food per pound of gain was practically the same for all the lots, averaging 6.6 cts. It was noted that there was great variation in growth in different weeks of the test, though generally speaking the fluctuations were similar with all the breeds.

The eggs of domestic ducks and hybrid ducks. A contribution to the study of hybridizing, G. LOISEL (*Compt. Rend. Soc. Biol.* [*Paris*], *59* (*1905*), *No. 36, pp. 587–589*).—According to the author's observations a domestic duck's egg weighs on an average 70 gm. and contains on an average 9 gm. shell, 24 gm. or 21 cc. yolk, and 37 gm. or 36 cc. white, this quantity of yolk being made up of 13 gm. water, 7 gm. fat, and 4 gm. protein, and the white of 31.3 gm. water and 5.68 gm. protein. The eggs laid by a domestic duck crossed with a wild duck weighed on an average 60.5 gm. and contained 7.26 gm. shell, 29.9 gm. white, and 22.76 gm. yolk made up of 10.15 gm. water and 12.61 gm. dry matter.

The author concludes that the eggs of the crossbred ducks though smaller are superior to domestic ducks' eggs from a food standpoint since they contain more dry matter, and that crossing with the wild form is advantageous for continuing the desirable characteristics of domestic ducks.

The guinea fowl, H. DE COURCY (*Jour. Bd. Agr.* [*London*]), *12* (*1905*), *No. 9, pp. 533–536*).—A summary of data on the feeding, care, and management of guinea fowls. As the author points out, guinea fowls are important factors in reducing the number of insects, and since they gather most of their feed the cost of raising them is less than with other poultry.

DAIRY FARMING—DAIRYING.

A comparison of wheat bran and cotton-seed meal for milk production, J. MICHELS and J. M. BURGESS (*South Carolina Sta. Bul. 117, pp. 18*).—The authors state that a review of the literature bearing on the feeding of cotton-seed meal shows that no ill effects follow its rational use as a food for milk production, and that bad results are probably due to one or more of the following causes: (1) Feeding the meal in conjunction with unsuitable roughage, (2) feeding it in a stale or musty condition, and (3) feeding it in excessive quantity.

The bulletin gives the results of a feeding experiment in which 21 cows were fed for 3 periods of about 4 weeks each for the purpose of comparing cotton-seed meal and wheat bran and of studying the influence of cotton-seed meal on the health of cows. During the first and third periods the grain ration consisted of 3 lbs. of bran and 3 lbs. of cotton-seed meal, and during the second period 4½ lbs. of cotton-seed meal.

The average daily butter-fat production was 14.51 lbs. during the first period, 14.96 lbs. during the second, and 14.14 lbs. during the third, showing an increase of 0.63 lb. for the cotton-seed meal period as compared with the average for the 2 periods when bran was fed. The cost of butter-fat production was 18.7 cts. per pound in period 1, 16.2 cts. in period 2, and 19.3 cts. in period 3, showing a saving of 2.8 cts. per pound in favor of the cotton-seed meal period. The butter-fat production of individual cows varied in cost from 12.9 to 19.5 cts. per pound. It was estimated that the bran-and-meal ration fed in periods 1 and 3 had the same manurial value as the meal ration fed in period 2.

The health of the cows was apparently uninjured by the heavy meal feeding. The butter made during the second period was appreciably firmer than that during the other periods, but in other respects it was the same.

In what way is the feeder responsible for unsanitary milk? W. H. JORDAN (*Hoard's Dairyman, 37 (1906), No. 2, pp. 31, 33, figs. 2*).—The author defines sanitary milk, mentions the different ways in which the milk producer may come into possession of unhealthy animals, and discusses the various causes rendering milk unsanitary after it is drawn. Particular attention is paid to the effect of the different feeding stuffs on milk.

The author believes that there are comparatively few commercial feeding stuffs, which, when properly fed, may not be used with perfect safety to the flavor and sanitary condition of the milk.

Milk-testing societies in Sweden (*Jour. Bd. Agr. [London], 12 (1906), No. 10, pp. 608, 609*).—It is reported that beneficial results have followed the introduction into Sweden of the system of cooperative milk testing known as control societies. From the figures given it appears that the average milk production per cow has increased from 3,134 lbs. to 3,539 lbs. during 4 years, while the food consumption has decreased. In 1904 there were over 200 control societies in existence in Sweden.

On obtaining pure milk for infants, children, and invalids, W. HEMPEL (*München. Med. Wchnschr., 53 (1906), No. 7, pp. 300–303, figs. 4*).—This is a general discussion of this subject with a description of a dairy in which extra precautions were taken to prevent the contamination of milk.

The bacteriological examination of such milk showed the presence of 1,600 bacteria per cubic centimeter as compared with 33,000 to 370,000 in sanitary or pasteurized milk from other sources. An illustrated description is also given of a faucet for drawing milk from receptacles so that the sample would be obtained equally from all layers from top to bottom.

The sale of milk for human consumption, M. CASALINI (*La vendita del latte per l'alimentazione umana. Turin, 1905; rev. in Rev. Gén. Lait, 5 (1906), No. 8, p. 190*).—This gives the results of a study of the sale of milk in several cantons and cities of Switzerland.

Methods of bacteriological examination of milk, F. H. SLACK (*Jour. Infect. Diseases, 1906, Sup. 2, pp. 214–222*).—This description of the technique and apparatus used in the laboratory of the Boston Board of Health is offered with a view of provoking discussion and eventually securing agreement on uniform and efficient methods.

The samples are obtained by means of large glass pipettes and placed in test tubes. Plates are made with 1 per cent agar having a reaction of +1.5 and are incubated in a saturated atmosphere for 24 hours at 37° C. The sediment obtained by centrifuging 2 cc. of milk is smeared over a space of 4 sq. cm. marked on a glass slide, dried with gentle heat, stained with methylene blue, and examined microscopically for bacteria and pus cells.

Milk containing not over 50 cells to the field of the 1/12 immersion lens is allowed to pass. While streptococci are found in small numbers in most market milk, a milk is condemned when the following tests are all positive: (1) Microscopic examination of the sediment showing streptococci, diplococci, or cocci; (2) the plate from the same sample showing colonies resembling streptococci colonies in excess of 100,000 to 1 cc., and (3) the broth culture from these colonies showing streptococci alone or in great excess of the other bacteria present.

The microscopic estimate of bacteria in milk, F. H. SLACK (*Abs. in Science, n. ser., 23 (1906), No. 580, p. 211*).—The centrifugal apparatus used and the method of examining the sediment for bacteria are described. The method is believed to have the following advantages: Rapidity of examination, accuracy, easily learned technique, and lack of costly apparatus. While not considered equal in accuracy to plate counts it is believed that the method can, in experienced hands, be used with safety for certifying milk.

The bacteriological examination of milk, A. C. HOUSTON (*London: P. S. King & Son, pp. 48; rev. in Brit. Med. Jour., 1906, No. 2356, pp. 452, 453*).—The author ascertained the amount of dirt in milk before and after centrifuging, and made bacteriological examinations of 20 samples of milk from each of five sources. The sources of contamination of milk are discussed and the desirability of establishing temperature and bacteriological standards for milk is considered.

In order to be free from objection, milk, according to the author, should fulfill the following conditions: One cc. should not show the presence of *Bacillus enteritidis sporogenes;* 0.001 cc., the presence of *B. coli;* nor 0.0001 cc., the presence of streptococci. The primary sediment after 24 hours should not exceed 100 parts per million, nor the secondary sediment after centrifuging 50 parts per million. The problem of improving milk supplies is discussed and several reforms considered practicable are enumerated.

Lactic-acid bacteria, W. M. ESTEN (*Abs. in Science, n. ser., 23 (1906), No. 580, p. 210*).—Studies have been made of the lactic-acid bacteria isolated from samples of milk received from nearly every section of the United States and Canada.

Two distinct groups of lactic-acid bacteria have been found, (1) gas-forming bacteria, (2) nongas-forming bacteria. The first group consists of *Bacillus coli communis* and *Bacterium lactis aerogenes*, which is considered identical with the *Bacillus acidi lactici* of Hueppe. The second group, in the opinion of the author, consists of only one species of bacterium with its varieties, namely, *Bacterium lactis acidi* of Leichman. The first group is aerobic and the second facultative anaerobic.

Milk not containing *B. lactis acidi* is considered a dangerous product if kept for any length of time, inasmuch as it then becomes a good medium for the growth of all kinds of putrefactive bacteria and disease germs, while milk containing this organism soon becomes nearly free from other forms.

Kinds of bacteria concerned in souring of milk, P. G. HEINEMANN (*Abs. in Science, n. ser., 23 (1906), No. 580, pp. 211, 212*).—The author believes that all so-called lactic-acid bacteria belong to two groups, the colon aerogenes group and the streptococcus group, and states that this arrangement is arrived at by a comparative study of culture characteristics of pathogenic, sewage, fecal, and milk streptococci.

The ordinary bacteria producing lactic fermentation are stated to be *Bacillus aerogenes lacticus* and *Streptococcus lacticus* either alone or in cooperation. *Bacillus coli* and peptonizing bacteria it is believed may also participate in the souring of milk. The gas-producing organism is present in large numbers in initial stages but is ultimately stopped by the development of the streptococcus. Lactic-acid bacteria are believed to be of intestinal origin, gaining access to milk with particles of cows' feces.

Since *Streptococcus lacticus* is invariably present in fresh milk collected with good precautions it is believed that the sanitary significance of streptococci in market milk needs further investigation.

A note on the indol-producing bacteria in milk, S. C. PRESCOTT (*Abs. in Science, n. ser., 23 (1906), No. 580, pp. 212, 213*).—In studying the relation between the occurrence of indol-producing bacteria and the total number present in milk, bacteriological examinations were made of 524 samples collected from 175 different farms. The results obtained with 278 samples are tabulated.

Of 13 samples containing above 1,000,000 bacteria per cubic centimeter, 9 samples or 70 per cent showed the presence of indol; of 2 samples containing between 500,000 and 1,000,000, 1 sample or 50 per cent showed the presence of indol; of 34 samples containing between 100,000 and 500,000, 14 samples or 41 per cent showed the presence of indol; of 229 samples containing between 25,000 and 100,000, 32 samples or 14 per cent showed the presence of indol; and of 133 samples containing 25,000 or less, 17 samples or 12 per cent showed the presence of indol.

Bacteriological studies of some milk samples of abnormal properties, R. BURRI and M. DÜGGELI (*Centbl. Bakt. [etc.], 2. Abt., 15 (1906), No. 22-23, pp.*

709–722).—This gives the detailed results of bacteriological studies of 4 samples of milk, one designated as smelling like Limburger cheese, one as having a dog odor, one having a bitter taste, and one with the marked taste and odor of Glarus cheese.

The quantitative determination of leucocytes in milk, A. R. WARD (*Abs. in Science, n. ser., 23 (1906), No. 580, p. 211*).—Comparative determinations of leucocytes in milk were made by the method of Doane and Buckley of the Maryland Station and that of Stewart of the Philadelphia Bureau of Health. The Doane-Buckley method was found to give more satisfactory results in duplicate determinations than the other method mentioned.

On the reductases of cows' milk, E. SELIGMANN (*Ztschr. Hyg. u. Infectionskrank., 52 (1906), No. 2, pp. 161–178*).—The author distinguishes superoxydase, the enzym in milk which decomposes hydrogen peroxid, from a reductase. Both are believed to be bacterial products.

Among the bacteria having catalytic action are cocci previously described by the author, and among those producing reductase is a small, thick, nonliquefying bacillus isolated from milk. No essential differences were observed between the reduction of a weak alcoholic solution of methylene blue and of Schardinger's reagent which contains formaldehyde in addition to the methylene blue.

Aside from the reducing substances in milk due to bacteria, there are also present in the milk, according to the author's investigations, decomposition products of the casein which have similar properties. It is thought possible that these may be formed in the milk ducts even by bacterial action. The oxydases in milk, on the other hand, are not considered products of bacterial growth.

Biological and biochemical studies on milk, C. J. KONING (*Abs. in Rev. Gén. Lait, 5 (1906), No. 8, pp. 186–189*).—This report, which is the fifth upon this subject, deals with the enzyms in milk. The abstract gives the numerous conclusions reached by the author, among which are the following:

Milk does not contain an oxydase. A positive reaction with the tincture of guaiac ought to be attributed to the presence of peroxid in the tincture. Peroxydases are always present in milk and their presence may be demonstrated by Storch's test. The reaction of the peroxydases has no relation to the presence of catalase in milk. Colostrum in certain instances gives a positive reaction with the Storch test and a negative reaction with guaiac. The bacteria commonly found in milk do not develop oxydase nor peroxydase when inoculated into sterile milk.

Diastases are always present in milk. Certain common milk bacteria are capable of producing traces of diastase when inoculated into sterile milk. In pathological processes in the mammary gland the amount of diastase in the milk is increased.

Schardinger's reaction is to be attributed to the enzym reductase, which is encountered commonly in milk, and which may be produced by bacteria. Pathological processes in the mammary gland increase also the amount of reductase in milk.

Catalase is present in milk and may be determined quantitatively. One hundred gm. of fresh normal milk is capable of decomposing 110 mg. of hydrogen peroxid in 2 hours. Catalase in milk may be produced by bacteria and may be increased by disease of the udder. The quantity of catalase in milk is also increased by the presence of leucocytes.

The author does not believe that chemical analysis and the determination of the refraction of the serum permit the recognition of the milk from diseased animals. In certain cases, however, such milk may be recognized by the cryoscopic method and by the determination of electrical resistance.

Proteolysis in cows' milk preserved by means of formaldehyde, W. G. TICE and H. C. SHERMAN (*Jour. Amer. Chem. Soc., 28 (1906), No. 2, pp. 189–194*).—Samples of milk preserved with formaldehyde in the proportion of about 1:1,000 were

kept under laboratory conditions and analyzed at different intervals. It was not considered certain that all bacterial action was suppressed in this way. The results obtained are shown in the following table:

Distribution of nitrogen in milk preserved with formaldehyde.

	Age of samples, in months.					
	11.	17.	26.	43.	28.	37.[a]
	P. ct.	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*
Lactose	4.25	4.37	4.46	4.46	4.68	4.76
Estimated loss of lactose	0.31	....	0.39	0.38	0.18	0.15
Acidity calculated as lactic	0.24	0.21	0.81	0.54	0.84	1.43
Percentage of total nitrogen, as—						
Casein	80.60	73.70	73.70	11.40	3.70	17.90
Albumin and syntonin	5.00	4.40	6.30	6.80	5.50	4.20
Proteoses	6.10	14.20	11.10	24.90	29.90	10.60
Peptones by bromin	0.60	0.90	2.30	10.10	10.70	....
Peptones by tannin	1.90	1.70	3.00	9.10	....	1.40
Peptones by phosphotungstic acid	2.20	1.90	5.20	10.70	....	....
Amino acids, etc., by tannin	6.40	5.90	5.90	47.80	50.20	65.90
Amino acids, etc., by phosphotungstic acid	6.10	5.70	3.70	46.20	....	....

[a] In this sample all of the nitrogen in a small lump of curd was estimated as present in the form of casein in the figures here given.

These results are noted as agreeing in essential features with the proteolysis brought about by galactase in the investigations of Babcock and Russell.

Domestic butter, A. McGill (*Lab. Inland Rev. Dept.* [*Canada*] *Bul. 107, pp. 12*).—This reports the analyses of 180 samples of butter intended for home consumption and collected during July, 1905. Only 1 sample contained borax and only 2 showed more than 15 per cent of water.

Contribution to the knowledge of Holland butter, A. Olig and J. Tillmans (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11* (*1906*), *No. 2, pp. 81–93*).—Analyses of numerous samples of butter made by the authors and of market samples are reported and discussed in completion of the work upon which a preliminary report was previously made (E. S. R., 16, p. 917).

The relative value of the different determinations for detecting adulteration of butter with animal fats is discussed. As fatty acids in food may, in part, pass into the butter, it is believed that data secured by methods depending upon the nature or amount of the fatty acids should be accepted only with a certain amount of caution. The most useful means of detecting foreign animal fats in butter are believed by the authors to be examination with the micropolariscope and determinations of the Reichert-Meissl and saponification numbers.

Butter making on the farm, E. H. Webster (*U. S. Dept. Agr., Farmers' Bul. 241, pp. 31*).—The various steps involved in butter making from the time of milking to the marketing and storing of the finished product are clearly set forth in a popular manner.

Use of pure cultures in the manufacture of Grana cheese, C. Gorini (*Rev. Gén. Lait, 5* (*1906*), *No. 8, pp. 169–172*).—Since 1903, 150 cheeses have been manufactured under practical conditions in order to determine the value of the cultures isolated by the author from excellent samples of this kind of cheese. The cheese was made and examined by a committee composed of manufacturers and dealers in Grana cheese.

While the work has not been carried on sufficiently long to warrant positive conclusions, the results so far are favorable to the use of the author's cultures. A value of 962 francs was placed upon 35 cheeses made with the pure cultures, while 35 made without the use of such cultures were valued at 689 francs. The author's method, as briefly stated in this article, is based upon strict hygienic measures in the production and handling of the milk as well as in the use of cultures.

Investigations on sour-milk cheese, C. H. ECKLES (*Ann. Agr. Suisse, 6 (1905), No. 8, pp. 323–332*).—In continuation of the investigations previously noted (E. S. R., 17, p. 291), the author made chemical and bacteriological examinations of 4 kinds of cheese from German sources and 2 kinds of Swiss cheese. The various organisms isolated were grown in sterile milk.

According to the conclusions reached by the author *Oidium lactis* commences to develop at once on the surface of cheese made without rennet and neutralizes gradually the acid produced by the lactic ferments. At the same time there is a development of a yeast, especially in places where the acid has been partly neutralized. These two organisms render the casein soluble, but the oïdium is considered the more important factor in this process. *Bacterium lactis acidi* is absent in the ripe cheese. The strong odor and the coating are attributed to the work of bacteria, among which is a yellow micrococcus which it is the author's intention to study later.

The ripening of Hartz cheese, II, C. H. ECKLES and O. RAHN (*Centbl. Bakt. [etc.], 2. Abt., 15 (1906), No. 25, pp. 786–790*).—In the first communication (E. S. R., 17, p. 291) it was reported that a yeast plays an important rôle in the ripening of this sour-milk cheese. Further experiments with sterile curd have confirmed this view. Descriptions are given of the various organisms found.

In a note to this article Rahn ascribes the disagreement in the results obtained by Eckles (see above) and himself to the fact that Eckles worked with sour milk and he with cheese.

Care of dairy utensils, O. ERF and C. W. MELICK (*Kansas Sta. Bul. 131, pp. 9–20, figs. 8*).—This consists of a general discussion of the care of dairy utensils with reports of two series of experiments in cleaning cream separators, the results of which are presented by the authors in the following conclusions:

"A cream separator should be thoroughly washed every time after using. A brush should be used on every part and piece, using 5 per cent solution of borax or other good washing powder. Rinse in hot water, or steam if possible. They should then be left to dry while hot. Wiping with an ordinary clean cloth contaminates utensils with innumerable bacteria.

"The bacterial contamination in milk is increased from three to five times by running it through a separator bowl which has been used and only flushed and left standing several hours. If only flushed while using, for several days, the contamination increases several times more, and such milk would be likely to be detrimental if fed to calves.

"The use of washing powder in flush water reduces the number of bacteria in the following batch of milk that is run through, and cleanses the separator more than hot water alone, but not sufficiently to warrant that method of cleaning.

"The use of a cream separator that is thoroughly washed reduces the number of bacteria in milk one-fifth to one-fourth.

"Improper cleaning is detrimental to a separator on account of the rust that accumulates on dirty or damp places. This may shorten the life of the machine many months, depending on the degree of cleanliness employed.

"Running milk through a dirty separator is similar to running it through a dirty strainer, with all of the filth of the previous milking left in it from twelve to twenty-four hours. The millions of undesirable bacteria from the dirt, manure, and slime lodged in the separator bowl spoil all the milk, to a greater or lesser degree, that passes through the machine.

"When properly used, a cream separator is a clarifier and to a certain extent a purifier of milk, but when carelessly used it is a source of filth and contamination."

Missouri State Dairy Association (*Mo. Bd. Agr. Mo. Bul., 5 (1905), No. 6, pp. 63, pl. 1, figs. 6*).—This is a summary of the proceedings of the sixteenth annual meeting of the Missouri State Dairy Association held in November, 1905. The addresses

which are printed in full deal with the value of silage for cows, European dairying, improvement of dairy cattle, guarding against the introduction of tuberculosis into dairy herds, the need of a dual purpose cow, profit in dairying, and quality in dairy products.

VETERINARY MEDICINE.

Diseases of cattle, sheep, goats, and swine, G. MOUSSU and J. A. W. DOLLAR (*London: Gay & Bird, 1905, pp. XVIII+785, pls. 17, figs. 316*).—The present volume is based largely on Moussu's "Maladies du Bétail" and other literature of German, English, and American origin. The subject-matter is classified according to the organs affected. The volume constitutes a valuable edition to the literature of veterinary science in English and is well illustrated.

Annual report of the State board of live stock commissioners (*Ann. Rpt. Ohio Bd. Agr., 59 (1904), pp. 713-774, figs. 15*).—The work of the State board of live-stock commissioners during the year is briefly outlined.

A detailed discussion is presented of a number of common diseases observed in the State, together with a map showing the distribution of each disease in the State. The more important of these diseases are anthrax, actinomycosis, glanders, hog cholera, swine plague, nodular disease in sheep, rabies, sheep scab, tuberculosis, etc. A copy is given of various laws passed by the State legislature relating to live stock and the duties of the live-stock commissioners. Notes are also given on the prevention of swine plague and hog cholera by P. Fischer.

The method of procedure of the board of live-stock commissioners in dealing with tuberculosis is outlined. The tuberculin test is being applied to cattle whenever request is made by the owner, and it is believed that in all instances the owner receives the full market value which could be expected for animals when found diseased.

Infectious diseases of animals and the live stock industry of the State, P. FISCHER (*Ann. Rpt. Ohio Bd. Agr., 59 (1904), pp. 394-400*).—Attention is called to the prevalence of various animal diseases in Ohio, particularly to glanders, tuberculosis, actinomycosis, rabies, trichinosis, and intestinal parasites. Brief recommendations are made regarding methods of preventing the outbreak and distribution of these diseases. The economic importance of animal hygiene is discussed.

Annual report on the distribution of animal plagues in the German Empire (*Jahresber. Verbr. Tierseuch. Deut. Reiche, 19 (1904), pp. VI+287, pls. 4*).—The present report is occupied with a discussion of the more important animal plagues, with particular reference to their distribution in various parts of the German Empire. The diseases included in the statistical account are anthrax, blackleg, rabies, glanders, foot-and-mouth disease, pleuro-pneumonia of cattle, horse mange, sheep scab, hog cholera, swine plague, fowl cholera, fowl plague, tuberculosis, etc. In an appendix to the report the distribution of these diseases is set forth in detail in a tabular form.

The veterinary section, A. THEILER (*Transvaal Agr. Jour., 4 (1905), No. 13, pp. 69-96*).—Particular attention is given to a discussion of the stock diseases of South Africa, including horse sickness, which is apparently transmitted by insects, rinderpest, heart water of domestic ruminants transmitted by *Amblyomma hebræum*, red water transmitted by *Rhipicephalus decoloratus*, biliary fever of horses transmitted by *R. evertsi*, malignant jaundice of dogs transmitted by *Hæmaphysalis leachi*, east coast fever transmitted by *Rhipicephalus appendiculatus* and *R. simus*, tsetse fly disease transmitted by *Glossina morsitans*, etc. J. M. Christy presents a report on measles in the pig with notes on the symptoms by which it may be recognized, diagnosis of the disease, etiology, and its economic importance.

Immunization with exudates and bacterial extracts, J. CITRON (*Centbl. Bakt. [etc.], 1. Abt., Orig., 40 (1905), No. 1, pp. 153-155*).—The immunity produced by

the use of aggressins is believed not to be different from that brought about by bacterial extracts. The author has demonstrated to his own satisfaction that aggressins are contained in bacterial extracts, and that the antiaggressins are identical with the complements. An active as well as a passive immunization can, therefore, be brought about in this manner.

The transportation of tetanus toxin to the spinal centers through the nerve fibers, N. TIBERTI (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig., 38* (*1905*), *Nos. 5, pp. 499–510; 6, pp. 625–644, pl. 1*).—In the author's experiments it was found that in guinea pigs and rabbits the ischiatic nerve may absorb the tetanus toxin and transport it to the nerve centers when the toxin is applied to the cut end of the nerve.

In the transference of the tetanus toxin the necessity of an intact axis cylinder is apparent. When tetanus toxin is introduced subcutaneously into a susceptible animal it is mostly absorbed by the lymphatics and passes thence into the blood. A small portion of the toxin, however, is found in the nerve trunks of the region. The tetanus toxin is transported to the nerve centers not through the lymphatics of the nerves but in the actual nerve fiber, particularly the axis cylinder. When the tetanus toxin is injected into the muscle it spreads about and comes in contact with the nerve fibers by which it is absorbed. Tetanus toxin introduced into the gastrocnemius muscles of guinea pigs is found in the ischiatic nerve within one and one-half hours.

Minute doses of tetanus toxin may, therefore, produce a symptom of the disease, provided it comes in direct contact with the nerves. If tetanus antitoxin is injected into a nerve trunk and toxin injected later into the corresponding muscles, the antitoxin will prevent the toxin from reaching the central nervous system.

A report on human and bovine tuberculosis, H. KOSSEL (*Brit. Med. Jour.*, *1905, No. 2344, pp. 1445–1449*).—The author presents a summarized account of his investigations in the German Imperial Health Office in cooperation with other investigators.

During the extensive studies carried on under these auspices the conclusion was reached that there are two distinct types of tubercle bacillus, the bovine and human. Tuberculosis in cattle is to be traced exclusively to infection with bovine tubercle bacillus. Swine are susceptible to both forms and human tuberculosis arises chiefly from an infection with the human bacillus. Tuberculous lesions in man may, however, be produced by the bovine tubercle bacillus and the disease may be transmitted to human beings by food derived from tuberculous animals, especially by cows' milk.

The origin of tuberculosis, methods of combating it, and feeding young animals, E. VON BEHRING (*Beitr. Expt. Ther., 1904, No. 8, pp. 1–138*).—This article contains an account of the principles upon which the author's method of immunizing cattle against tuberculosis is based, the details regarding methods of performing this operation, and considerable controversial matter.

While cattle appear to be more susceptible than any other animal to natural infection with tuberculosis, it has been found in the author's experiments almost impossible to inoculate them by means of the hypodermic method. During the past 6 years 20 cattle have received, hypodermically, enormous quantities of tubercle cultures, in some cases as high as ½ liter, without producing any infection. When these animals were killed and carefully examined several months or even years after inoculation no trace of tubercle bacilli was found and no evidence of infection. If this is found to be generally true it will readily explain the negative results from the hypodermic inoculation of cattle with tubercle bacilli of human origin. Cattle are readily infected by intravenous inoculation.

The author believes that calves and children may be immunized against tuberculosis by preventing the occurrence of live tubercle bacilli in the food, and by feeding them milk treated with formaldehyde so as to destroy the tubercle bacilli and leave uninjured the immunizing bodies found in tuberculous milk. For this purpose

formaldehyde may be added to milk at the rate 1 part to 40,000. It is maintained by the author that the protective bodies are regularly found in the blood when the animal is in the process of recovery from infection.

The only true remedy for infectious diseases appears, therefore, to consist in the use of protective bodies obtained from the blood or other body fluids of animals which have recovered from the disease in question. The chief danger of infection of both calves and children is believed to occur in early life from drinking milk containing tubercle bacilli. The appearance of pronounced symptoms of the disease may not be noted until later life.

Immunization of cattle against tuberculosis, E. VON BEHRING (*Beitr. Expt. Ther., 1905, No. 10, pp. 1-21*).—In this article a brief review is presented of the work thus far carried out at the Marburg University under the author's direction, especially on the problem of vaccinating cattle to render them immune against tuberculosis. An attempt is made to present definitions of certain terms used in connection with this problem, especially virus, vaccine, jennerization, pasteurization, immunity, etc.

It is reported that about 10,000 cattle have been immunized according to the author's method with good results. This work has been done partly by men working directly under the author and partly by other veterinarians. The small proportion of failures which have occurred seem to be capable of explanation, so that no serious defect has been found in the method.

The action of tubercle bacilli of different origin, R. LINK (*Arch. Hyg., 53 (1905), No. 3. pp. 264-274*).—In order to test as delicately as possible the differences in morphology and pathogenic action between tubercle bacilli of human and bovine origin the author inoculated rabbits in the anterior eye chamber with accurately weighed quantities (0.0001 to 0.0002 gm.) of cultures of tubercle bacilli. The bacilli of human origin came from an advanced case of consumption, that of bovine origin was obtained through the kindness of Professor von Behring.

A preliminary test of these cultures showed that guinea pigs inoculated in the body cavity with the human bacilli died within 23 days of generalized tuberculosis, while the bovine bacilli did not seem to be so virulent when inoculated in this manner. The results obtained in various experiments are presented in a tabular form. It appeared from these experiments that the bovine bacilli are short rods without any granulation, while the human tubercle bacilli frequently show granulation. Guinea pigs inoculated with human bacilli showed large numbers of the tubercles, while the bovine bacilli appeared more likely to produce diffuse inflammatory processes.

No differences were observed in the pathological processes whether the animals were inoculated with 0.0001 or 0.0002 gm. of the cultures. In general the course of the disease was more severe after infection with bovine than with human tubercle bacilli. A general infection, however, took place in all cases.

Tuberculosis in cattle and tuberculin tests of the station herd, J. M. SCOTT (*New Mexico Sta. Bul. 55, pp. 15, pls. 5*).—Notes are given on the nature, symptoms, method of infection, and prevalence of tuberculosis. The nature of tuberculin is briefly stated, together with directions for making the tuberculin test.

The literature relating to the subject of feeding tuberculous milk is discussed. Two calves from tuberculous cows were allowed to take the milk of these cows. Both of these calves developed tuberculosis, while a third calf, also from a tuberculous cow, did not develop the disease when not allowed to take its mother's milk. It is believed that tuberculosis could be eradicated from the Territory by a thorough application of the tuberculin test and the destruction of reacting cattle. A test of the station herd, consisting of 19 calves, indicated that 15 per cent were tuberculous.

Vaccination against tuberculosis in Melun, E. THIERRY (*Jour. Agr. Prat., n. ser., 10 (1905), No. 50, pp. 749, 750*).—A brief account is given of experiments carried out in Melun by Vallée. The cattle on which the experiments were made

have all been slaughtered, and the results show that in vaccination may be had the most satisfactory method of controlling tuberculosis.

The experimental disease caused by inoculation with tubercle bacilli from which the oil has been removed, J. CANTACUZENE (*Ann. Inst. Pasteur, 19 (1905), No. 11, pp. 699–714*).—It has long been known that tubercle bacilli killed by heating to a temperature of 120° C. remain toxic and when inoculated into guinea pigs may cause serious disease or death.

The author wished to determine the effect of the complete removal of fat from tubercle bacilli. For this purpose bacilli in glycerin bouillon were kept at a temperature of 60° C. for 1 hour on 5 successive days. The dead bacteria were then filtered, dehydrated in vacuum, and treated in a Soxhlet apparatus by a successive exposure to methyl alcohol and petroleum ether. After from 36 to 48 hours all trace of fat had disappeared. The bacteria thus treated were of bovine origin and of a virulence sufficient to kill guinea pigs within 36 hours after inoculation with a dose of 20 cm.

Within 2 hours after inoculation of a fatal dose of bacteria treated as just described the temperature of guinea pigs fell several degrees. This subnormal temperature persisted for 6 hours. During the progress of the disease the blood becomes eosinophilous, the kidney hyperemic, the muscle fibers of the heart swollen, and other pathological lesions appear. When smaller doses were given the subnormal temperature was rapidly followed by fever, emaciation of the animal, and the formation of tuberculous nodules or abscesses which were later resorbed entirely.

Further experiments showed that tubercle bacilli, killed and deprived of their fat, cause an acute necrosis of the leucocytes when given in fatal doses, while in small doses they produce similar symptoms of less duration and an enormous hypertrophy of the spleen. Animals inoculated with such bacilli react in a typical manner to tuberculin for a period of several weeks. When such bacilli are treated with Gram's mixture of iodin and potassic iodid they cause no necrosis. The active resorption of treated bacilli may be caused by daily injections of iodid of potash after inoculation.

Ranilla, J. C. SEGURA (*Bol. Sec. Fomento [Mexico], 5 (1905), No. 1, I, pp. 140–166, figs. 12*).—Ranilla has been shown to be a disease of cattle identical with Texas fever of this country and tristeza of South America. It is transmitted from diseased to healthy cattle by means of the cattle tick. The pathogenic cause of the disease is the same blood parasite which is observed in Texas fever, and treatment for the disease should, therefore, be the same as adopted against Texas fever.

Abortion in cows, T. W. CAVE (*Jour. Southeast. Agr. Col. Wye, 1905, No. 14, pp. 245–248*).—A brief account is given of contagious and noncontagious abortion in cows, with a discussion of remedies for the contagious form. The plan adopted by the author consisted in the isolation of all aborting cows, destruction of the fetuses and fetal membranes, and a thorough application of Izal at the rate of 1 to every 80 to 200 parts of water.

The treatment of infectious vaginal catarrh, ATTINGER (*Berlin. Tierärztl. Wchnschr., 1905, No. 50, pp. 845–848*).—The literature relating to this disease in cattle is critically reviewed.

As a result of the author's study of this disease it is concluded that it is not possible to adopt rational governmental orders for the control of the disease, for the reason that the nature of the disease is not sufficiently well known. It is not absolutely certain that the disease is infectious or caused by micro-organisms. The results of experiments thus far made are at variance regarding the methods of treatment, and opinions differ widely also regarding the economic importance of the disease.

Parasitic gastro-enteritis, F. G. ASHLEY (*Vet. Rec., 18 (1905), No. 912, p. 448*).—For a number of years the author has observed cases of gradual emaciation in young steers grazing on swampy pastures. At first some of the cases were thought to be tuberculosis, but later recovered. Occasionally acute symptoms developed and

the animals died within about 60 hours. Post-mortem examinations made on such cases showed the presence of *Strongylus gracilis*, and the disease is therefore to be considered as of parasitic origin.

Mortality in cattle caused by eating poison tulip, J. D. STEWART (*Agr. Gaz. N. S. Wales, 16 (1905), No. 10, pp. 956–959, figs. 3*).—In a herd of 96 cattle 25 died from eating *Homeria miniata*. In some cases death occurred within a few hours, while other cases lingered for 2 or 3 days and some recovered. The mucous membrane of the fourth stomach and of the intestines was greatly inflamed. Feeding experiments showed that 3 oz. of the plant was sufficient to cause serious symptoms of poisoning in heifers.

On the occurrence of hydrocyanic acid in Johnson grass, M. E. JAFFA (*Cal. Bd. Health Mo. Bul., 1 (1905), No. 2, pp. 11, 12*).—The death of cattle in Los Banos, California, was reported as due to eating Johnson grass. A preliminary analysis of this grass showed conclusively that it contained hydrocyanic acid. A quantity of fresh Johnson grass was then obtained, and upon analysis was found to contain 0.05 per cent hydrocyanic acid, while barnyard grass from the same locality contained no poison.

The poisonous action of Johnson grass, A. C. CRAWFORD (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 90, pt. 4, pp. 6*).—The literature relating to the chemistry of Johnson grass and related species is briefly reviewed in connection with bibliographical notes. Some reports have been received since 1902 regarding the supposed poisonous action of this grass. In a sample obtained from Santa Rosa, California, positive tests for hydrocyanic acid were obtained. The grass is reported as poisonous when grown on either irrigated or nonirrigated lands, but especially so when the grass matures rapidly.

Diseases of sheep, T. W. CAVE (*Jour. Southeast. Agr. Col. Wye, 1905, No. 14, pp. 239–244, fig. 1*).—The author discusses pernicious anemia in sheep due to the presence of *Strongylus contortus* in the fourth stomach. Many cases of this disease came under his attention. The worm is described and notes are given on its life history. The best means of preventing infestation is to keep close watch upon the condition of the water supply of sheep.

Anthrax in the horse, J. R. MCCALL (*Vet. Rec., 18 (1905), No. 911, pp. 429, 430*).—A brief account is given of this disease in horses with special reference to a case in which the symptoms develop very rapidly, resulting in death. The source of infection was probably turnips which came from a neighborhood where anthrax had occurred. It was also possible that infection was spread to some extent by traffic in wool which was carried on in connection with the same stable. Judging from the clinical symptoms in this case, the bacilli gained entrance through the lymphatics of the throat.

Variations in the content of agglutinins and precipitins in the blood during an infection with glanders, A. BONOME (*Centbl. Bakt. [etc.], 1. Abt., Orig., 38 (1905), Nos. 5, pp. 601–611; 6, pp. 732–740*).—The experiments reported in this paper were carried out on horses, asses, cats, and guinea pigs.

The blood serum of horses during experimental infection with glanders and also during artificial immunization against the glanders bacillus shows a pronounced increase in the agglutinin content. This increase takes place more rapidly after inoculation through the nasal mucous membrane than when infection takes place through the alimentary tract. During the period of mallein reaction the agglutinating power of the blood of glanderous horses is increased. The same may be said for the blood of horses which no longer react to mallein.

It was found that the agglutinating power of the serum of glanderous horses was entirely destroyed by heating for 1 hour at a temperature of 62 to 65° C. The agglutinating power reappears, however, upon the addition of normal serum of other animals in the proportion of 1:2.

The diagnostic value of agglutination in glanders, J. SCHNÜRER (*Centbl. Bakt. [etc.] 1. Abt., Orig., 39 (1905), No. 2, pp. 180–187*).—The author describes in some detail the technique of the method including the taking and sending of blood samples, repetition of this process, the preparation of the tests, and the judgment of results. It appears that between the 2 groups of decidedly positive and negative results some uncertain cases will appear which require a repetition of the test.

The unity of dourine, G. E. SCHNEIDER and M. BUFFARD (*Ann. Inst. Pasteur, 19 (1905), No. 11, pp. 715–717*).—Attention is called to the difficulty of demonstrating the blood parasite in cases of dourine. The author was able, however, to determine the presence of *Trypanosoma rougeti* as the cause of dourine in France.

Studies on Trypanosoma duttoni, THIROUX (*Ann. Inst. Pasteur, 19 (1905), No. 9, pp. 564–572, pl. 1*).—This blood parasite was found in the blood of house mice, and notes are given on its appearance and on successful methods of cultivating it. The various forms which it assumes in artificial cultures are also noted. The organism may be reinoculated from one specimen to another of house mice and also to other species of the same genus. Rats and guinea pigs, however, seem to be refractory. The blood of animals recovered from infection contains no agglutinin toward *Trypanosoma duttoni*.

Trypanosomes in the blood of inoculated animals, A. NISSLE (*Arch. Hyg., 53 (1905), No. 3, pp. 181–204*).—The observations reported in this article were made on laboratory animals inoculated with *Trypanosoma brucei, T. equinum*, and *T. lewisii*. Rats, white mice, and guinea pigs were the chief experimental animals employed. The author describes in some detail the morphological changes undergone by the blood parasites in these experimental animals, their movements, microscopic structures, reaction of the blood cells toward them, and other related matters. A brief bibliography of the subject is appended to the article.

Experimental trypanosome diseases, L. HALBERSTAEDTER (*Centbl. Bakt. [etc.], 1. Abt., Orig., 38 (1905), No. 5, pp. 525–532, pl. 1*).—The author reports in considerable detail the degrees of infection of white mice and rabbits with the trypanosomes of dourine, mal de caderas, and nagana. The technique of staining trypanosomes is also briefly considered.

On trypanosomes and their presence in the blood of Brisbane rats, C. J. POUND (*Proc. Roy. Soc. Queensland, 19 (1905), No. 1, pp. 33–38*).—In recent years the author has frequently observed trypanosomes in the blood of rats. Notes are given on the technique of examination of fresh and stained specimens of rat blood containing the trypanosome of surra.

A new endoglobular hematozoan, J. J. VASSAL (*Ann. Inst. Pasteur, 19 (1905), No. 4, pp. 224–231*).—An endoglobular protozoan is found in *Sciurus griseimanus*. Inoculation experiments showed that this organism is not pathogenic for man, monkeys, rabbits, guinea pigs, or pigeons. Brief notes are given on its appearance.

The spread of plague infection by insects, W. HUNTER (*Centbl. Bakt. [etc.], 1. Abt., Orig., 40 (1905), No. 1, pp. 43–55*).—From a review of the literature of the subject and from the author's experiments it is concluded that insects may carry *Bacillus pestis* and may, therefore, be the means of disseminating this organism over wide areas.

Sucking insects, such as fleas, bugs, etc., mechanically convey infection from place to place in the same manner as other insects. Apparently the danger from the bites of the insects has been exaggerated. It appears that the spread of infectious diseases by insects is accomplished indirectly by the deposition of plague bacillus on foods, clothing, and household material.

The tapeworms of Australia, N. A. COBB (*Agr. Gaz. N. S. Wales, 16 (1905), Nos. 2, pp. 153–168; 3, pp. 209–219; 4, pp. 301–318; 7, pp. 619–631, figs. 34*).—The anatomy of tapeworms is discussed, and notes are given on the methods of collecting them for study and on the life history of these pests. In the special discussion of the

subject attention is given to tapeworms of the cat, dog, and horse, with especial reference to those forms which are of economic importance as parasites of man or important domestic animals.

The method of distribution of trichina embryos, C. Stäubli (*Vrtljschr. Naturf. Gesell. Zürich, 50 (1905), No. 1-2, pp. 163-176*).—By means of feeding experiments with mice, guinea pigs, and other experimental animals the author studied the method of distribution of trichina embryos after hatching in the intestines.

During these experiments infested muscle tissue from human beings, pigs, and rats was used. When samples of the cardiac blood were taken for study, a number of trichina embryos was found in every case in the blood, the number varying from 2 to 230 in the different samples. In order to demonstrate the trichina embryos most easily it was found desirable to stain with acid eosin and methylene blue. Trichina embryos were found in the blood within 7 days after the infested meat was eaten.

The author's investigations on laboratory animals lead him to believe that the young embryos are not carried through the vena portæ, but through the thoracic duct. This view of the subject of the distribution of trichina embryos makes it possible to understand more readily how they make their way so rapidly from the intestines to various muscles of the body.

An infectious pneumonia of rabbits and its treatment with antiserum, H. J. Südmersen (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig., 38 (1905), Nos. 5, pp. 591-600; 6, pp. 713-732, figs. 2*).—The investigations reported in this paper have been under way for 3 or 4 years and were undertaken to discover the cause of an epidemic among laboratory rabbits.

Post-mortem examinations indicated that *Bacillus A* was present in the lungs of 68 per cent of all rabbits affected with the disease. The same bacillus was obtained in pure cultures from the lungs of guinea pigs affected with pneumonia. Pneumonia in rabbits is usually accompanied by a nasal discharge. It is probable that certain forms of pneumonia may arise secondarily to other infections, but the majority of infections are due to *Bacillus A*. In cultivating this organism a toxin is produced.

It was found possible in the injection of attenuated cultures to protect rabbits against subsequent infection. The immune serum produced in such rabbits showed pronounced agglutinative and bactericidal properties. The use of the serum is very effective in producing immunity, but the immunity is passive and not of long duration.

Serum treatment for dog distemper, A. H. Meis (*Berlin. Tierärztl. Wchnschr., 1905, No. 50, pp. 848, 849*).—A test was made of Piorkowski's serum in the treatment of dog distemper. No effect was produced by the use of this serum and the author believes that it is useless to attempt the manufacture of protective sera so long as the micro-organism of the disease is not definitely known.

The study of mixtures of antirabies serum and fixed virus, P. Remlinger (*Compt. Rend. Soc. Biol.* [*Paris*], *59 (1905), No. 37, pp. 658-660*).—The author found that intracerebral injections of fixed virus and antirabies serum in rabbits were quite without effect. The action of this mixture is pronounced, however, when inoculated under the skin or in the peritoneum. The effect of the mixture is to produce a pronounced resistance to rabies.

The protection of dogs against rabies by mixtures of fixed virus and antirabies serum, A. Marie (*Compt. Rend. Soc. Biol.* [*Paris*], *59 (1905), No. 37, pp. 637-639*).—The author found that when dogs were inoculated with a mixture containing 3.5 cc. of antirabies serum and 2.5 cc. of fixed virus they were thereby rendered immune to fatal doses of rabies virus. In other experiments the amount of the mixture used varied from 10 to 60 cc., but in general it is recommended that the mixture consist of $\frac{1}{3}$ virus and $\frac{2}{3}$ antirabies serum. By using this mixture it appears

to be possible to protect dogs against rabies by a single injection for a period of at least one year.

The so-called premonitory fever as a symptom of experimental rabies, J. VON LÖTE (*Centbl. Bakt. [etc.], 1. Abt., Orig., 39 (1905), No. 1, pp. 32–35*).—From careful determinations of the temperature of normal rabbits the author believes that the body temperature is sufficiently regular to prevent any confusion between normal temperatures and the fever which is regarded as premonitory of an outbreak of rabies. This fever was considered as a perfectly natural occurrence indicating the beginning of the disease.

The action of radium rays upon the virus of rabies in vitro and in the animal organism, G. TIZZONI and A. BONGIOVANNI (*Centbl. Bakt. [etc.], 1. Abt., Orig., 39 (1905), No. 2, pp. 187–189*).—In the authors' experiments it was found that the virus of rabies in vitro or in the animal organism is rapidly destroyed under the influence of radium rays.

Sleepy disease of chickens, C. DAMMANN and O. MANEGOLD (*Deut. Tierärztl. Wchnschr., 13 (1905), No. 50, pp. 577–579, fig. 1*).—On an estate in Westphalia a disease broke out among chickens and affected nearly all of a flock of one hundred. The affected fowls showed a roughness of plumage, swollen eyes, paleness of the comb, and lameness. The appetite appeared to be fairly good during the course of the disease.

When a post-mortem examination was made, striking symptoms of hemorrhagic septicæmia were found. The musculature was permeated with bloody effusions and red spots were observed in the mucous membrane of the intestines. The spleen was considerably enlarged, and hemorrhagic patches were observed in other parts of the body. A capsule-bearing streptococcus was found in large quantities in the blood. This organism is described under the name *Streptococcus capsulatus gallinarum*. It is either aerobic or anaerobic, and differs in many respects according to the animal in which it is inoculated or the artificial medium in which it is cultivated. It is quite susceptible to heat and is destroyed in 2 minutes by exposure to a 1 per cent solution of carbolic acid.

The disease may be readily transmitted by inoculation of virulent blood to other chickens. When thus inoculated the most striking symptom in the fowls is sleepiness, and this symptom determined the name of the disease. The disease may be transmitted by subcutaneous inoculation to pigeons, rabbits, and white and gray mice.

The protective properties of blood from animals affected with fowl cholera and immune to aggressin, E. WEIL (*Arch. Hyg., 54 (1905), No. 2, pp. 149–184*).—A thoroughly protected immune serum appears not to exist in a case of fowl cholera. The positive results obtained by active immunization, however, make it probable that blood of animals treated with an exudate containing aggressin contains protective substances.

The author's experiments were carried out on rabbits and the immune serum used in the experiments came from rabbits which have been immunized by means of a very virulent culture of fowl cholera bacillus. Serum thus obtained was tested on mice, and it was found that 0.1 cc. of the serum was sufficient to protect mice against a bacterial dose which killed control animals in less than 24 hours. When tested on rabbits it was found that from ½ to 1 cc. of the protective serum was a safe and effective dose for one of these animals. Experiments with pigeons and chickens were not so satisfactory. When the protective serum and the active virus were inoculated at the same time it was found that the serum was sufficient to prevent the development of the disease in mice, rabbits, and guinea pigs.

RURAL ENGINEERING.

Hydrologic work of the U. S. Geological Survey in the Eastern United States, M. L. Fuller (*Rpt. Internat. Geogr. Cong., 8 (1904), pp. 509–514*).—An outline of the work of the division of hydrology which deals with underground waters.

An American and a European bibliography is being prepared, statistics regarding wells, and technical papers on pumping and drilling are published from time to time, and both the scientific and economic sides of underground water supply are investigated. A compilation of the law of underground waters is under way.

The author discusses also the relation of hydrology to geography and the mapping of hydrologic features.

Hydrographic work of the U. S. Geological Survey, G. B. Hollister (*Rpt. Internat. Geogr. Cong., 8 (1904), pp. 515–522*).—A general review of the work undertaken by the hydrographic division, which includes measurements of the quantity of water, both on the surface and underground, and records of stream flow extending over long periods, as well as studies of the quality of waters for domestic and industrial uses. The publications of this division include annual reports and the well-known series of Water-Supply and Irrigation Papers.

Prehistoric irrigation in the Navaho Desert, E. L. Hewett (*Records of the Past, 4 (1905), No. 11, pp. 323–329, pls. 4*).—Remains of large irrigating systems have been found in Gila and Salado valleys, which show great engineering skill, in sharp contrast with the extremely crude earth and stone dams commonly found around pueblo ruins.

The writer, in a trip across Navaho Desert, found well-preserved ruins near Una Vida of a reservoir puddled with clay and riprapped, fed by a diverting ditch; a stone dam at Kinklizhin with a waste way cut in the solid rock; and at Kinbineola a reservoir in a natural depression with a ditch 2 miles long run on a fairly uniform grade, showing stone retaining walls in places.

These remains show "the existence of a system of prehistoric irrigation in the midst of the Navaho Desert that is intermediate in its plane of development between the advanced system of the Gila drainage and the very rudimentary form common to the entire pueblo region. It represents but modest achievement as compared with that of the Gila people, but marked advance over the common achievements of the prehistoric pueblos."

Irrigation in Mildura, C. J. Grant (*Victorian Inst. Engins., 1905, pp. 2–18, figs. 2*).—The duty of water pumped into a canal and distributed to 9,000 acres in fruit and vines is found to be somewhat higher than in America and India, the depth applied being 2.2 feet measured at the head of the canal.

The loose sandy "pine" soils require less water when well cultivated than the heavy "blue brush" soil. On account of great heat and dryness, three irrigations in a season of 125 days, applied in deep furrows, are made in preference to a number of very light applications. The failure of rating flumes to give close results with very light grades has led to the design of a new device for measuring water to individual laterals, by means of an inverted siphon arranged so that a current meter is turned by the water as it rises, a series of dials indicating discharge in cubic units. In the main canal submerged weirs have been used for measurements to avoid unnecessary increase in pumping head.

Season and crop report of the Bombay Presidency for the year 1904–1905, H. S. Lawrence (*Dept. Land Rec. and Agr. Bombay, Ann. Rpt. 1905, pp. 12+LXI*).—This report contains statistics as to rainfall, areas of crops, yields, and prices for the Bombay Presidency proper, and the Sind.

The season was one of short rainfall, and therefore of decreased acreage. As a consequence prices were in general higher than usual. Cotton prices, however, were an

exception to this, although the crop was short, the low prices being attributed to the large American crop. As a result of the low rainfall the area irrigated from the canals and tanks was considerably reduced, but there was a large increase in the area irrigated from wells. In the Bombay Presidency proper more than half of the total irrigated area (789,476 acres) was irrigated from wells. In the Sind about one-sixth of the total area (3,000,000) was irrigated from wells.

The use of water in France, A. BACKHAUS (*Mitt. Deut. Landw. Gesell., 20 (1905), No. 32, pp. 247–254, figs. 13*).—Irrigation in the departments of southeastern France is reviewed, and the working of State aid for canals is described, with the object of dissipating popular errors as to the extent and possibilities of irrigation in France.

In this connection it is pointed out that "it is an error to suppose that southern France is short of rain and that irrigation is a prerequisite for farming, but while crops may be raised without irrigation, the application of water insures intensive crops such as market gardens, green fodder, and crops raised by hand labor." It is admitted that while the French can not show as fine meadows as are found in Germany, they excel in canal construction and in irrigation organization. "The unity of the entire water and land system is an important thing in France, and similar provisions are needed in Germany, especially those for placing water rights on a common basis for all Germany and the management of all water affairs under one office. The French system provides for companies or syndicates administering their own affairs under government inspection, usually with government subvention."

As an example of the working of government aid on a large canal, a case is described where a grant of $700,000, the total cost being $1,100,000, was made to a syndicate, besides a guaranty of 4.5 per cent on the rest of the investment, in the expectation that the earnings would more than defray interest and maintenance. But owing to "a lack of intelligent interest on the part of the farmers, in the face of the example of other departments where irrigation has been successfully practiced for centuries," the government has had to pay an annual deficit to cover the guaranty.

The necessity of using government funds only in cases where self-help is stimulated thereby is urged, cases being cited where a single grant or bonus was made with no guaranty with good results. The duty of water, rates paid, and winter irrigation are discussed. The leaching of valuable constituents from the soil is considered an important matter, in France and Germany, and the liberal use of fertilizers is recommended. An estimate of the actual profits of irrigating meadows and other crops is given.

Irrigation. A few hints on the preparation of the land and the practical application of water, F. G. CHOMLEY (*Agr. Gaz. N. S. Wales, 16 (1905), No. 10, pp. 1003–1010, figs. 11*).—A résumé of practice in New South Wales and California, describing furrow and check methods of irrigating, cement ditches, and wooden sluice boxes.

The size of irrigated farms (*Forestry and Irrig., 11 (1905), No. 11, pp. 516–518*).—An argument in favor of making the homestead unit under national reclamation projects 80 acres rather than 40 acres, based on the probability that alfalfa will be the main crop for a number of years and that more than 40 acres in hay is needed for the reasonable support of a family.

The diminished yield of underground waters in southern California (*Engin. Rec., 52 (1905), No. 15, pp. 405–407*).—Underground waters are an important source of supply for irrigation in this region, there being 3,000 artesian wells and 1,600 pumping plants, developing 400 to 500 cu. ft. per sec., irrigating about 150,000 acres.

The artesian conditions are peculiar in the valley of southern California, the artesian basins being formed by a sheet of clay parallel to the surface, at no great depth, overlying deep beds of detritus. These basins lie in a series along the course of Santa Ana River, and constitute reservoirs for its storage. Owing to the low cost of driving wells into these basins the drafts on the supply have for years exceeded

inflow, causing a large and continuous shrinkage in the artesian area, even in ordinary wet years. The writer believes these drafts will be restored by extraordinary wet seasons, but that the irrigated area should not be increased hereafter.

The value of meadows and their irrigation, STRECKER (*Fühling's Landw. Ztg., 54 (1905), No. 20, pp. 678–693*).—After showing the high importance of meadows to animal industry the possibility of a large increase in hay crop by the correction of streams, drainage, and especially by irrigation, is urged.

It is estimated that the crop on one-third of the total area of 15,000,000 acres may be increased nearly 50 per cent, thus increasing the total yield by about 16 per cent. Suggestions are given for laying out irrigated meadows. The importance of irrigation and drainage to remove humic acid by aeration and other salts by solution, and the distribution of fertilizers by irrigation are discussed.

The writer concludes that (a) small streams may be cheaply used; (b) water is most easily controlled on low riparian meadows; (c) the simplest system should be used to distribute water; (d) the regulation of stream flow by numerous small dams is a benefit to power users except during low water; (e) small storage reservoirs are useful; (f) irrigated hay if properly handled brings a better price than common hay; (g) the drainage from small towns should be utilized; (h) ground water may be raised to advantage by wind power; (i) steep land will absorb more rainfall if furrowed transversely; (j) a small quantity of water will insure a good aftermath.

Water as a plant food, BACKHAUS (*Fühling's Landw. Ztg., 54 (1905), No. 22, pp. 757–762*).—The quantity of water used by plants in Germany in producing one part of dry matter is estimated as 350 parts, or about 14 inches of rain for a crop of 4.5 tons to the acre.

In hay culture, light, heat, and plant food are usually abundant, the crop depending solely on available water. Experiments during 1904 showed increases in yield due to irrigation as follows: Oats—grain 35 per cent, straw 56 per cent; wheat—grain 94 per cent, straw 169 per cent; grass—1st cut 220 per cent, 3rd cut 348 per cent; hemp 46 per cent.

The actual value of increase in crop for each cubic meter of water applied was 1.3 cts. to 3.3 cts., equivalent to $27 to $70 per acre foot.

The author reviews the methods to be employed, noting the relation of irrigation to water power and the value of local organization. Deep culture, increase of humus, the selection of suitable plants, the chemical action of water, the value of sewage irrigation, and the importance of land drainage are discussed.

Cultivation of salt lands, A. ROLET (*Jour. Agr. Prat., n. ser., 9 (1905), No. 22, pp. 710–712*).—A method of removing sodium chlorid by flooding in square checks and draining in open ditches is described, and for the complete reclamation of salt lands for the use of vineyards, it is recommended that rice be grown one or two years, grain two or three years, and then rice again to complete the removal of salt.

Laying out rice plantations, G. CARLE (*Jour. Agr. Prat., n. ser., 10 (1905), No. 46, pp. 626–630, figs. 3*).—Directions for surveying and constructing dikes, laterals, drains, and leveling checks for rice fields, with special reference to quantitative estimates of cost. The methods suggested are adapted to rough lands and to crops other than rice.

A report on terrestrial magnetism and meridian line work in Louisiana, W. C. STUBBS, G. D. HARRIS, ET AL. (*Geol. Survey La. Bul. 2, pp. 49, pls. 6*).—This bulletin summarizes the results of work which has been done with a view to establishing meridian lines in Louisiana for the use of surveyors, engineers, and land holders, and of measurements which have been made to ascertain the changes that are continually taking place in the earth's magnetic field within the State.

The model farm, F. GRAFTIAU and E. WARNANTS (*La ferme démonstrative. Liège: Henri Poncelet, 1905, pp. 42, pls. 2, figs. 3*).—A description of a model farm plant, built

for the Belgian section of the Exposition Universelle at Liège in 1905, giving a complete bill of materials used and an account of the society which built the plant.

Wind for electric power, F. VON LEPEL (*Mitt. Deut. Landw. Gesell., 20 (1905), No. 45, pp. 373-375, figs. 2*).—The author believes that while wind power has been limited hitherto to pumping and grinding, neither of which operations requires constant speed, by connecting a dynamo and accumulating the current in a storage battery, all ordinary needs for farm power, including heat and light, may be met.

A crude device which allows the drive belt to loosen and slip on its pulley is proposed to regulate speed and prevent injury to the dynamo, but the method of stepping up the speed from 12 revolutions per minute at the mill to 900 at the dynamo is not described. An editorial note appended says:

"The article . . . is based partly on material furnished by windmill makers, and does not give data for an estimate of the actual power of windmills. The statement of actual work done by Swedish plants seems too high . . . for according to the assertions of German makers, considerably larger mills would be required for the same service. Many attempts have been made in Germany to use wind for electric power, but it is known to us that all the large electric concerns strongly believe it to be impracticable . . . on account of the unsteady power and speed."

Replying to this comment (21 (1906), No. 1, pp. 3, 4) Dr. von Lepel refers to a book on the subject by Prof. La Cour for quantitative data, and deplores the lack of interest on the part of large manufacturers in small plants for farms.

A letter is also published from a Dresden firm urging the necessity of auxiliary steam or gas power in addition to storage batteries, and describing a successful wind-electric plant for 120 lamps run by a modern 24-ft. mill, using a horsepower machine with four horses for auxiliary power.

The electrical value of wind power (*Sci. Amer., 93 (1905), No. 21, pp. 394, 395*).—A description of the plant of C. F. Brush in Cleveland, Ohio, which has been in use for sixteen years to run 100 16-candlepower lights, and a plant in Wittkeil in Schleswig that develops 30 horsepower in an 8-mile wind, for lighting a town. Other methods which substitute compressed air or elevated reservoirs for the expensive storage battery are suggested, but it is admitted that the problem is as yet unsolved.

British progress in pumps and pumping engines, P. R. BJÖRLING (*London: Archibald Constable & Co., 1905, pp. XII+92, figs. 97*).—This brief practical treatise on British pumps is the second volume of a series called National Engineering and Trade Lectures, edited by B. H. Morgan, and is a review of the various kinds of pumps, with notes on their selection for general and special purposes, intended to stimulate colonial and foreign trade in British machinery.

The farm automobile, G. VOIGTMANN (*Landw. Masch. u. Geräte, 6 (1906), No. 1, pp. 1-5, figs. 8*).—An improved gasoline traction engine is described, with a discussion of its advantages over fuel-burning engines. The illustrations show field trials of the machine.

Construction and ventilation of farm buildings (*Bul. Maine Dept. Agr., 4 (1905), No. 3, pp. 77-99*).—This bulletin contains five short articles and eight pages of correspondence relating to barns and silos.

Implements and machinery at the Smithfield Show (*Impl. and Mach. Rev., 31 (1906), No. 369, pp. 1033-1072, figs. 31*).—This report contains notes on 120 exhibits. The machines that seem to attract the most interest are swath turners, farm traction motors, milking machines, and combined planters and manure spreaders. An ingenious turnip thinner is described, and a number of root and feed cutters. Many new farm engines and motors are noticed.

Farm machinery in Belgium during the past twenty-five years, J. PYRO (*Ann. Gembloux, 16 (1906), No. 1, pp. 1-12*).—A cursory and somewhat technical

review of recent progress in the design, manufacture, and use of various farm machines, with special reference to the implement industry in Belgium.

Ancient Egyptian farm implements, A. DE CÉRIS (*Jour. Agr. Prat., n. ser., 10 (1905), No. 40, pp. 433-436, figs. 12*).—A description of the four-man plow and other implements found in inscriptions, with notes on their manner of use.

Recent improvements in hay making (*Canad. Impl. and Vehicle Trade, 12 (1906), No. 3, pp. 28, 29*).—The great importance of the quick curing of hay has encouraged the improvement of hay tedders, the most recent of which is the side-delivery rake.

"These machines are put into the hay immediately after it is mowed, the primary object being to uncover and heat a section of the meadow surface as the best means available in returning the hay to that section of forcing the curing by bottom heat, as well as by the incidental stirring. The rows can be re-turned at any time afterward on to the hot surface alongside, the repeated soft action of the machine doing no injury."

The corrosion of fence wire, A. S. CUSHMAN (*U. S. Dept. Agr., Farmers' Bul. 239, pp. 31*).—This bulletin is published as an answer to numerous complaints from farmers of the rapid rusting of galvanized fence wire.

The manufacture of iron and mild steel and the methods used in drawing and galvanizing wire are described, with special reference to the use of manganese, which is shown to be the possible cause of deterioration, owing to its influence on electrolytic action. It is admitted, however, that further tests are necessary to establish this theory. Besides decreasing the percentage of manganese it is proposed to ground the wires at intervals, so as to reduce electrolysis. A heavier coating of zinc, such as is used on telephone wires, is thought to be worth trying, but probably too expensive.

Teaching agricultural engineering in land-grant colleges, C. J. ZINTHEO (*Engin. News, 54 (1905), No. 25, pp. 658-662*).—The enormous increase in the use of farm machinery and in its cost as compared to other items of agricultural expense has contributed to make the study of farm machinery an important branch of instruction in agricultural colleges.

Although the schools of European countries are in the lead in agricultural engineering, the agricultural colleges in Wisconsin, North Dakota, Minnesota, and Iowa now offer more or less complete courses of a very practical sort, and several other colleges are organizing the same sort of instruction. The writer includes under agricultural engineering drainage, irrigation, roads, farm motors, and farm buildings as well as machinery.

RURAL ECONOMICS.

Farming as a business enterprise, E. C. PARKER (*Amer. Mo. Rev. of Reviews, 33 (1906), No. 192, pp. 62-67*).—This article emphasizes the growing importance of business methods on the farm, and outlines the investigations which are being carried on by the Minnesota Station, in cooperation with this Department, to determine the cost of producing field crops and live-stock products under farm conditions in Minnesota.

"Methods of keeping 'farm accounts' in a simple, practical manner are being worked out from the experience gathered," and it is hoped that a system of accounting may be devised which will enable the farmer to choose rationally from the various crops and the various kinds of live stock which may be produced upon his farm, and also to be able to compare the relative profitableness of the different methods of carrying out the operations of the farm.

The poor and the land, H. R. HAGGARD (*London: Longmans, Green & Co., 1905, pp. XLI + 157, pls. 6*).—This is a report on the agricultural colonies established by the Salvation Army in the United States and at Hadleigh, England. Fort Romie, in California, and Fort Amity, in Colorado, are described and discussed at considerable length. The purpose of these colonies is the removal of poor people from the cities

and their establishment in the country where they may live by carrying on agriculture.

The following quotation gives a brief statement of the conclusions reached by the author: "At both Fort Romie and Fort Amity I found the settlers healthy, happy, hopeful, and, almost without exception, doing well. Beginning in nearly every case with nothing, moreover, in the course of about four years at Fort Romie these settlers are now worth an average of about $2,000 per head above all their debts and liabilities to the Salvation Army and others, and at Fort Amity an average of about $1,000. . . .

"The venture, however, has not proved so prosperous to its founders, the Salvation Army, who on these two settlements have incurred a total loss of about $50,000. This loss is due to four causes: (1) The fact that the settlements were established by aid of money borrowed at a heavy rate of interest, namely 5 and 6 per cent, and that the settlers were charged too little for their holdings which they pay for by installments. (2) The considerable initial cost of the estate both at Fort Romie and Fort Amity. (3) The fact that the settlers were first established at Fort Romie before the soil had been properly irrigated and at once confronted by a three years' drought. (4) The circumstance that at Fort Amity the land, which was virgin prairie, proved exceptionally hard to work; also to be impregnated with alkali or natural salts, whereof the presence was totally unsuspected at the time of buying, of which alkali it has cost much money to be rid by deep draining. So it comes about that although the settlers are doing so well, the Salvation Army have been called upon to pay $50,000 for their experience."

Grazing on the public lands (*U. S. Dept. Agr. Forest Serv. Bul. 62, pl. 1, map 1*).—This bulletin contains a discussion of the condition of the grazing areas of the public domain, and the regulations which are essential to the orderly and economical use of these lands.

On some of the ranges the supply of grass and other stock feed is now more abundant than in former years, but on the greater number the grazing value of the lands has greatly diminished in recent years. Overstocking is the principal cause of the deterioration. Where pastures have been fenced or where the control of the range has been secured through the ownership of the watering places by the ranchmen, the condition of the range has been improved. But where many ranchmen are struggling to secure the same forage, a short-sighted policy is inevitable, the ranges are overstocked and their carrying capacity greatly reduced, to the detriment of the grazing industry. As a result, a large majority of the ranchmen are dissatisfied with the present condition of affairs, and favor "Government control of the ranges under reasonable regulation."

"The sentiment among stockmen seems to be rapidly changing in this regard, and many who formally opposed any form of control or leasing are now in favor of such action, provided the change is brought about gradually and with care to avoid any unnecessary disturbance of present range divisions and methods of use. It is almost the unanimous opinion of stockmen that in the adoption of any new system of management for the public grazing land, ample provision should be made for the gradual settlement of the country by actual home seekers."

The leasing of tracts of grazing land to individuals seems to be the most favored plan of regulation. The report contains an extended discussion of the systems of leasing State lands in Texas and Wyoming, and of the lands of the Northern Pacific Railway in eastern Washington.

The world's grain production in 1905 (*Die Getreideproduktion der Welt im Jahre 1905. Budapest: Royal Hungarian Minister of Agriculture, 1905, pp. 92*).—Statistics on the production of wheat, rye, barley, oats, and maize in 1905 are given for the different countries of the world. The countries are grouped into those importing and those exporting grain.

AGRICULTURAL EDUCATION.

Agricultural education in Lancashire, J. Bayne (*Roy. Lancashire Agr. Soc. Jour., 1905, pp. 26–41, figs. 12*).—Following a brief statement concerning the origin of agricultural education in Lancashire, the writer outlines the policy of the educational work and describes its different phases.

These include agricultural instruction at the Agricultural College of the Harris Institute, Preston; instruction in dairying both at the permanent dairy school on the county council farm, Hutton, near Preston, and also by means of migratory teachers; instruction in poultry work at the poultry school on the county council farm and by means of migratory teachers; lectures on agriculture, dairying, poultry keeping, horticulture, veterinary science, and bee keeping at various centers in the county; advisory agricultural work in the county and experimental work at the farm and elsewhere in the county.

All of the agricultural work is under the control of an agricultural subcommittee, consisting of representatives elected by the education committee of the Lancashire County council, by the council of the Harris Institute, and by the council of the Royal Lancashire Agricultural Society. The agricultural course at Harris Institute is intended to prepare young men and women for the practical work of the farm, and extends over 4 years, each session beginning in September and ending about the first of May. Each student is not only given free instruction, but if not a holder of a junior or senior agricultural scholarship is allowed a sum not exceeding $2.40 per week by the county council. Tuition fees are required of nonresident students.

The instruction given at the dairy school, the poultry school, and by means of lectures in different parts of the county is confined to the single branch of agriculture under consideration, while the agricultural work in Harris Institute includes also instruction in chemistry, zoology, mathematics, electrical engineering, mechanical engineering, drawing, natural science, physics, surveying, and woodwork.

Agricultural college extension (*Mass. Bd. Agr. Nature Leaflets 1–32*).—Beginning March 28, 1900, the State Board of Agriculture of Massachusetts has published 32 nature leaflets, all of which have a more or less direct economic bearing, as the following titles indicate:

(1) Canker Worms, A. H. Kirkland (pp. 3, figs. 4); (2) Tent Caterpillars, A. H. Kirkland (pp. 3, figs. 4); (3) The Black Knot of the Plum and Cherry, G. E. Stone (pp. 4, figs. 2); (4) Spraying Mixtures for Insects and Plant Diseases, H. T. Fernald (pp. 3); (5) The White-marked Tussock Moth, H. T. Fernald (pp. 3, fig. 1); (6) The Spiny Elm Caterpillar, H. T. Fernald (pp. 4, figs. 3); (7) Potato and Apple Scab, G. E. Stone (pp. 4, figs. 2); (8) Insects Injuring Lawns, H. T. Fernald (pp. 3, fig. 1); (9) Poison Ivy, G. E. Stone (pp. 4, figs. 3); (10) The Datanas, H. T. Fernald (pp. 2, fig. 1); (11) Quince Rust, G. E. Stone (pp. 3, figs. 2); (12) Winter Birds at the Farm, E. H. Forbush (pp. 7, figs. 3); (13) Peach Leaf Curl, G. E. Stone (pp. 4, figs. 2); (14) Owl Friends, E. H. Forbush (pp. 6, figs. 3); (15) Bird Houses, E. H. Forbush (pp. 6, figs. 4); (16) Our Friend the Chickadee, E. H. Forbush (pp. 8, figs. 4); (17) Bordeaux Mixture, G. E. Stone, (pp. 5, figs. 2); (18) Plant Lice or Aphids, H. T. Fernald (pp. 3, fig. 1); (19) Edible Weeds and Pot Herbs, G. E. Stone (pp. 5, fig. 1); (20) Massachusetts Weeds, G. E. Stone (pp. 7, figs. 2); (21) Potato Rots, G. E. Stone (pp. 4, figs. 4); (22–25) Hints for Outdoor Bird Study, E. H. Forbush (pp. 22, figs. 4); (26) The Brown-tail Moth, A. H. Kirkland (pp. 4, figs. 4); (27) The Gypsy Moth, A. H. Kirkland (pp. 4, figs. 5); (28) The Garden Toad, A. H. Kirkland (pp. 5, fig. 1); and (29–32) School Gardens, with directions for planting and care of school gardens, suggested crops, and the educational results of school-garden work, H. D. Hemenway (pp. 29, figs. 11).

Popular agricultural education in Jamaica, J. R. Williams (*Jour. Jamaica Agr. Soc., 9 (1905), No. 11, pp. 403–409*).—The causes of early failure and of more

recent success in efforts to provide agricultural instruction in the schools of Jamaica are here discussed by the Jamaica inspector of schools.

The writer points out as some of the essentials of success the importance of preparing the way by creating interest and sympathy in the work among the adult population and of giving much attention to the preparation of teachers for the new requirements imposed upon them. Nearly half of the teachers now at work in the elementary schools have received training in teaching agriculture.

The most important future needs are said to be the establishment of a college of agriculture in the island and the development of agriculture in the elementary schools as a feature of the educational work, not as a separate subject to be specialized, that is to say, agriculture should be taught primarily because of its educational value.

Syllabus of illustrated lecture on profitable cattle feeding, F. B. MUMFORD (*U. S. Dept. Agr., Office Expt. Stas., Farmers' Inst. Lecture 4, pp. 21*).—The topics specially considered in this lecture, designed for farmers' institute workers, are conformation to type, quality, breeding, age, and feeding methods, as these are the factors of most importance in determining profit in cattle-feeding operations. A list of 45 lantern slides designed to illustrate the lecture is included.

Syllabus of illustrated lecture on silage and silo construction for the South, A. M. SOULE (*U. S. Dept. Agr., Office Expt. Stas., Farmers' Inst. Lecture 5, pp. 31*).—In addition to the syllabus there are added more detailed directions for building various types of wooden silos, with estimates of materials and cost. A list of references is also given.

Syllabus of illustrated lecture on essentials of successful field experimentation, C. E. THORNE (*U. S. Dept. Agr., Office Expt. Stas., Farmers' Inst. Lecture 6, pp. 24*).—This syllabus, which was prepared for the purpose of aiding farmers' institute lecturers, gives suggestions on the way of carrying out successful field experiments. In this connection the selection of the soil, arrangement of plats, preparation of land for crops, planting and cultivation, harvesting, weighing, keeping the records, and the continuity of the work are discussed. A list of 32 lantern slides illustrating methods for conducting agricultural experiment work is given, together with a list of references to publications bearing on the subject.

MISCELLANEOUS.

Eighteenth Annual Report of Georgia Station, 1905 (*Georgia Sta. Rpt. 1905, pp. 111–119*).—This contains the organization list, a brief report by the president of the board of directors, a report of the director on the work of the station during the year, and a financial statement for the fiscal year ended June 30, 1905.

Hawaiian Sugar Planters' Station Report, 1905 (*Hawaiian Sugar Planters' Sta. Rpt. 1905, pp. 59*).—This consists of a general report on the work of the station during the year by the committee of the Hawaiian Sugar Planters' Association having this matter in charge, and appendixes containing detailed reports of the divisions of agriculture and chemistry, entomology, and pathology and physiology.

The same matter is also issued in the form of a yearbook consisting of the report proper, and in addition reprints of Bulletins 12–15 of the division of agriculture and chemistry, parts 1–6 of Bulletin 1 of the division of entomology, Bulletins 1–3 of the division of pathology and physiology, and a revised reprint of the report of the station for 1904, all of which have been previously noted or are noted elsewhere in this issue.

NOTES.

Idaho University and Station.—The main building of the university was destroyed by fire March 30. The building was the first one erected upon the grounds, and was a large and imposing structure containing the administrative offices, assembly hall, museum, and a large number of class rooms and laboratories. The experiment station office, library, and laboratories were located in the basement and were also destroyed. The building was insured for $106,500, which will cover about half the loss upon it.

Maryland Station.—Raymond Outwater, of the George Washington University, has been appointed assistant chemist of the station. Investigations on sweet corn are planned to be carried on at the station in cooperation with the Bureau of Chemistry and the Bureau of Plant Industry of this Department. M. N. Straughn will be in immediate charge of this work. The legislature has increased the appropriation for maintenance by $5,000, making it $10,000 a year. The appropriation for the State horticultural department has been increased to $12,000, with the provision that $4,000 shall be used by the station for investigation.

Massachusetts Station.—A contract has been entered into with the Bureau of Soils for the establishment of a substation in Concord, Mass., for experiments with asparagus. The cranberry insects are to be studied in the cranberry districts of this State the coming season by an expert employed for the purpose. Cooperative experiments with fertilizers for cranberries will also be undertaken.

Frederick R. Church, assistant agriculturist, has resigned to assume the management of a large farm. He is succeeded by Erwin S. Fulton, who has been an assistant in chemistry at Wesleyan University and in the nutrition investigations at Middletown.

Ohio Station.—The State legislature has established a department of forestry at the station, to carry on studies in forestry as related to the industry of the State. No additional appropriation is made for carrying on this new line of work.

Oklahoma College and Station.—C. E. Quinn, assistant in agronomy, has resigned to enter the employ of the Bureau of Plant Industry of this Department. L. A. Moorhouse, now on leave attending the University of Illinois, has been appointed professor of agronomy in the college and agronomist in the station, beginning July 1. W. L. Burlison, a graduate of the college in 1905, who has since been attending the University of Illinois, has been appointed temporary assistant in agronomy in the college and station. H. G. Beard, Shawnee, Okla., has resigned from the board of regents. His successor has not been appointed.

The new shop and gymnasium building has been completed. Work on Morrill Hall is progressing at a rate which insures its completion by the opening of the fall term.

Rhode Island College and Station.—Howard Edwards, M. A., LL. D., professor of English literature and modern languages at the Michigan Agricultural College, with which institution he has been connected for the past fifteen years, has been elected president of the college, to succeed Kenyon L. Butterfield at the close of the college year. The station is planning for extensive cooperative experiments with farmers of the State this season.

Vermont College and Station.—Morrill Hall, the new agricultural building for which appropriation was made last year, and for which a site has recently been secured, will probably be 60 by 90 ft. and at least three stories in height above the basement. It is expected to construct the building of brick, with stone basement and trimmings. The work will be pushed as rapidly as possible, in the hope that it may be made ready for the opening of the fall term.

The new Weather Bureau station, erected by the U. S. Department of Agriculture on the university grounds, has been completed. The building stands nearly opposite the experiment station farm, is of colonial style, and presents a very pleasing appearance. The observer of the station will live in the building and will have one assistant.

Semicentennial of Maryland Agricultural College.—The fiftieth anniversary of the establishment of the college was celebrated with appropriate exercises March 6. The date which these exercises commemorated was that of the passage of the act by the legislature establishing and endowing the college, which two years later was located on its present site.

President R. W. Silvester reviewed the history of the State charter, outlined the position of the college, and gave special attention to the important function of the agricultural colleges in training men for the great basic industry. Governor Warfield presented documentary evidence to show that the movement for the Maryland College started in a memorial to the legislature in 1837.

President Ira Remsen, of Johns Hopkins University, defined science, its aims and applications. He showed the application of pure science and made an eloquent plea for the value of investigation and discovery which was undertaken for the purpose of advancing knowledge, but not with a commercial idea or a direct view to its practical applications. He urged that it is only through such work that the fund of knowledge can be added to and the basis enlarged for application in the arts.

Prof. L. H. Bailey declared that the agricultural college stands for the freest democracy in education. He showed the youthfulness of agricultural science in comparison with pure science, and the great value of science in agriculture. In comparing American and German experimental work, he stated that the former is practical but not fundamental, while the German is fundamental without being practical. The American has, as he said, revolutionized everything in farming since Washington's time, except the man, and attention is now being given to reaching the man. He prophesied that while at present the farm often does not inspire and satisfy the educated boy, because it is so unprogressive, in future only the educated and thinking man can succeed on the farm, as the requirements of farming are becoming so much greater and success more difficult to attain. He extolled the great opportunities for young men in this country to assume leadership in rural and agricultural affairs.

Secretary Wilson urged the importance of teaching agriculture in the rural schools and of training teachers for this instruction. He asserted that "the power of the farm to create and produce has not half been reached," any more than has the power of the man to produce. The agricultural cóllege teaches the boy how to do things, how to do them better, and how to produce more. The work of the agricultural college of the future was sketched and great development and usefulness was predicted for it.

Prof. F. A. Soper spoke for the alumni of the college. The occasion was one of interest and enthusiasm for agricultural education and for the Maryland College.

Agricultural Chemical Experiment Station at Vienna.—According to a reorganization of this station, noted in a recent number of the *Wiener Landwirtschaftliche Zeitung*, the station now includes the following divisions: (1) Plant production and vegetation station at Korneuberg, O. Reitmair, chief, and Ferdinand Pilz, assistant; (2) dairying and feeding, Max Ripper, chief; (3) wine and other alcoholic drinks, fruit juices, and vinegar, Bruno Haas, chief, and Victor Kreps, Walter Fischer, and

Julius Schuch, assistants; (4) moor culture, uses of peat, moor culture station at Admont, and heating materials, William Bersch, chief, and Dr. Zailer, assistant; (5) chemical-technical investigations for private persons, J. F. Wolfbauer, chief, and Edward Hoppe and Adolf Halla, assistants; (6) chemical-technical investigations for officials, Franz Freyer, chief, and Theo. Schmitt, assistant.

Tea Experiment Station in India.—In accordance with plans previously noted (E. S. R., 16, p. 217), the Indian Tea Association has established an experiment station at Heeleaka, near Moriani, Assam, known as the Heeleaka Experimental Station and located on a tea plantation set out in 1862 and 1865. The object of this station is to study some of the partly solved problems concerning the character of soil suited to tea production, the best methods of production, and the best system for the renovation of deteriorated tea, as well as many other less practical but no less fundamental problems concerning the relation of the various operations of tea culture to the composition of the tea leaf, and hence to the quality of the tea. The experiments undertaken thus far have dealt solely with problems of tea culture, but it is proposed to take up also the equally important problems of manufacture.

Poultry Fattening Station in Ireland.—The Department of Agriculture and Technical Instruction for Ireland has established a station at Avondale, Rathdrum, for training young men in the breeding and fattening of poultry, with a view of preparing them to undertake the management of fattening stations in other parts of the country. Apprenticeships may extend over a period of from 6 to 12 months.

Experimental Farm at Nangeenan, West Australia.—The Western Australia department of agriculture has started an experimental farm at Nangeenan, 95 miles east of Northam, for the purpose of testing the possibilities of agriculture in the dry region east of the Avon Valley. The farm was located in June, 1904, but no crops were grown until last year. The results of the first season's tests were encouraging, indicating that with proper care in preparing the ground and putting in the crops good yields can be had.

International Conference on Plant Breeding.—The Third International Conference on Plant Breeding will be held at Westminster, England, July 30–August 3, 1906. Prof. W. Bateson will be president of the conference.

Conference for Education in the South.—The Ninth Annual Conference for Education in the South will be held at Lexington, Ky., May 2–4. One session of the conference will be devoted to agricultural education, at which addresses will be delivered by Dr. James W. Robertson, of the new Macdonald College at St. Ann de Bellevue, near Montreal, and Dr. Seaman A. Knapp, of this Department. Among those who are expected to give addresses at other sessions are Prof. N. S. Shaler, of Harvard; Dr. Brown Ayres, of the University of Tennessee, and Hon. John W. Yerkes, of Washington, D. C.

Agricultural Schools in Porto Rico.—The Report of the Commissioner of Education of Porto Rico for the fiscal year ended June 30, 1905, shows that during that year 11 agricultural schools were maintained. This is 3 less than were maintained in 1904, the decrease resulting from inability to secure teachers properly qualified to give instruction in agriculture. The average daily attendance at these schools was 41, and the average number of days actually taught was 170.

The reports of superintendents of different districts indicate varying degrees of success in carrying on these schools, depending largely upon the ability of the teacher and his attitude toward the subject. The superintendent of District No. 2, with headquarters at Carolina, reports very enthusiastically concerning the agricultural school in his district. He says that the pupils have produced a good crop of cane, and have demonstrated that vegetables can be grown to advantage. The superintendent is convinced that "agricultural schools can be made a success if we have men who know how to work, and will get right out and work with their own hands, as this teacher has done."

The superintendent of District No. 19, with headquarters at Bayamon, reports that "the agricultural school has continued its excellent work and rendered entire satisfaction." This school has given considerable attention to the beautification of the school grounds, in which work the girls have assisted.

Attention is also called to agricultural work inaugurated in a rural school in this district. The necessary tools were loaned by the Department of Education, while the Porto Rico Agricultural Experiment Station, at Mayaguez, furnished seed and many valuable suggestions as to planting and cultivating. Each boy was given a plat of ground and seed for planting. The experiment has proven a success in every way, fine crops of garden truck being grown. Five other schools have asked to enjoy the same privilege.

Agriculture in the Primary Schools of New Zealand.—The New Zealand department of agriculture is encouraging the introduction of agriculture into the primary schools of that country. The biologist of the department has been conducting experiments for several years in connection with the Mauriceville West Primary School in teaching the elements of agricultural science and school gardening. In his report on the school garden work, he says: "The time allotted to this work is 2 hours per week, and it has been found that not only does it not interfere with the effective teaching of other subjects, but it is actually an assistance, providing, as it does, additional subjects for composition exercises, increasing the pupils' powers of observation, and inculcating habits of neatness and methodical arrangement."

Kaerehave Agricultural School.—According to a note in the Journal of the Board of Agriculture for January, 1906, a school for the training and instructing of renters and laborers of both sexes was established near Ringsted, Denmark, with Government aid in November, 1903. The pupils are chiefly girls and farm hands, from 20 to 25 years of age, who attend from 5 months to a year, and older persons who attend the short courses of 11 days. During the time the school has been in operation, it has been attended by 375 pupils in long courses and 800 persons in short courses. The land for the school (54½ acres) was donated by the town of Ringsted. The department of agriculture granted a loan of $16,170 to aid in starting the school.

A New School of Agriculture in France.—A school of agriculture has recently been established at Hennebont (Morbihan), which is well equipped with land for demonstration purposes, orchards, domestic animals, and other agricultural material.

South African School of Forestry.—The government of Cape Colony is establishing the South African School of Forestry at Tokai, to provide a course of instruction for training young men for practical and scientific work in South African forestry. Provision is being made for 10 resident students at Tokai, who will be received from the South African College and other similarly equipped institutions in the colony after having completed the theoretical work in forestry.

Two New Veterinary Journals.—The great progress which has been made in recent years in the study of animal diseases in the Tropics has made it desirable to publish a periodical in which contributions relating to tropical diseases in various countries will be gathered together for the benefit of workers engaged in this line of investigation. It often happens that the library facilities for such workers in the tropical countries are not the best, and it is, therefore, especially desirable to get all the recent material in as available a form as possible.

The *Journal of Tropical Veterinary Science*, the first number of which has just been issued, seeks to supply this need. Attention is called, in an editorial note in the first number, to the fact that many of the tropical diseases in animals are infectious also for man, and more information is desired regarding the cause and control of these diseases both for the guidance of intending settlers in tropical countries and for the benefit of animal industry in those regions.

A new journal devoted to infectious diseases of animals and methods which contribute to the hygiene of farm animals (*Zeitschrift für Infectionskrankheiten para-*

sitäre Krankheiten und Hygiene) has recently appeared under the editorship of Dr. Robert Ostertag, of Berlin, and other collaborators. This journal is intended for use in the publication of original articles relating to bacterial and parasitic diseases of animals and general farm hygiene. The journal on meat and milk hygiene, published for many years under the editorship of Dr. Ostertag, was found to be quite satisfactory for the inclusion of articles relating strictly to these subjects, but a large mass of other material not dealing with the special topics of meat and milk inspection suggested the desirability of publishing the new journal to contain such material.

In addition to original articles the journal also contains general summaries of literature on special topics, and reviews of books and smaller articles dealing with bacterial diseases and the general problems of bacteriology in relation to pathology.

Miscellaneous.—*The Garden Album and Review* is the title of a new English monthly magazine of horticulture, edited by John Weathers, well known author of "A Practical Guide to Garden Plants," etc. A prominent feature of the new magazine will be 4 colored plates of plants, flowers, or fruits in each number. The magazine will be devoted to gardening interests in all of its branches, both open air and under glass. The first number contains 16 quarto pages and includes an index to the most important articles and illustrations in various other horticultural periodicals.

The *Monthly Weather Bulletin*, issued by the Weather Bureau of this Department, continues the series heretofore published under the title *Weather Crop Bulletin of the Weather Bureau.* It will hereafter be devoted to weather conditions.

The 25 county normal schools of Michigan will this year graduate 400 students for teachers in the rural schools. The expense to the State is said to be about $65 a teacher.

The annual meeting of the German Association of Naturalists and Physicians will be held this year at Stuttgart, September 16–22.

Joseph Pyro, professor of rural engineering in the School of Agriculture of Gembloux, Belgium, died at that place March 5, 1906. He was born at Liège November 28, 1843. Professor Pyro was a recognized authority in his chosen field and had achieved signal success in promoting education and investigation in rural engineering. He took a prominent part in the discussions of the International Congress of Agricultural Mechanics held at Liège in August, 1905.

Prof. Alexander Müller, agricultural chemist, died at Stensjoholm, Sweden, January 28, in his seventy-eighth year. He was appointed in 1856 director of the agricultural experimental section of the agricultural academy at Stockholm, and consulting agricultural adviser for Sweden and Norway. His earlier published work dealt mainly with questions of dairying, hygiene, and the treatment of soils; of late it related to the cleansing of towns.

Prof. N. Zuntz has been chosen rector of the agricultural high school at Berlin for the customary period of one year.

Dr. A. Backhaus, of Berlin, has been called to the organization and direction of an agricultural high school in connection with the University of Montevideo in Uruguay.

O

EXPERIMENT STATION RECORD.

VOL. XVII. MAY, 1906. No. 9.

An important report upon the need of elementary training for the great productive industries has been presented to the Massachusetts legislature by a special commission, headed by President Carroll D. Wright as chairman. Agriculture is included among these industries, and definite provision is made for it in the general scheme by which the public-school system is to be enriched and expanded along industrial and vocational lines.

The commission has been engaged for some time in an investigation of the relation of the public schools to the various industries of the State, the preparation which the schools afford for the life work of the pupils, and the economic aspects of the question. It finds that the productive industries, including agriculture, manufactures, and building, depend mainly upon chance for recruiting their service. These industries are only touched educationally in their most advanced and scientific forms. No instruction whatever is furnished at public expense in the theory and practice of these occupations, and while agriculture is recognized by the State in its aid to the agricultural college, there is no preparatory work leading up to it in the same way that the high schools lead up to the other colleges. The same is true to a large extent of the schools of technology.

The children who leave school to enter employments at the age of 14 or 15 have had no training to develop their actual productive value or efficiency, and this is largely true of those who remain in school until 16 or 18. The added years, it is pointed out, are to a considerable extent lost time, so far as developing efficiency in productive employments is concerned. In the case of both classes of children the employment upon which they enter after leaving school is determined by chance.

These conditions, the commission holds, have an important economic bearing, for they tend to increase the cost of production, to limit the output in quantity, and to lower the grade in quality.

Industries so recruited can not long compete with similar industries recruited from the ranks of technically trained persons.

The commission concludes that the elements of industrial training, agriculture, domestic and mechanical sciences should be taught in the public schools, and it presents a strong argument in support of this conclusion. "The State needs a wider diffusion of industrial intelligence as a foundation for the highest technical success, and this can only be acquired in connection with the general system of education into which it should enter as an integral part from the beginning. The latest philosophy of education reinforces the demands of productive industry by showing that that which fits a child best for his place in the world as a producer tends to his own highest development physically, intellectually, and morally."

Two lines are suggested in which industrial education may be developed—through the existing public-school system and through independent industrial schools. It is recommended that cities and towns so modify the work in the elementary schools as to include instruction and practice in the elements of productive industry, as applied to agriculture and the mechanic and domestic arts, and "that this instruction be of such a character as to secure from it the highest cultural as well as the highest industrial value." It is also urged that the work in the high schools be so modified "that the instruction in mathematics, the sciences, and drawing shall show the application and use of these subjects in industrial life, with special reference to local industries; . . . that is, algebra and geometry should be so taught in the public schools as to show their relations to construction, botany to horticulture and agriculture, chemistry to agriculture, manufactures, and domestic science, and drawing to every form of industry."

In addition to these modifications the commission recommends that towns and cities provide new elective industrial courses in high schools, for instruction in the principles of agriculture and the domestic and mechanic arts, with both day and evening courses, so as to accommodate persons already employed in trades; and furthermore, that part-time day courses be provided for children between the ages of 14 and 18 years who are employed during the remainder of the day, so that instruction in the principles and the practice of the arts may go on together.

The above relates entirely to the existing public school system, whose integrity the scheme proposes to preserve. For the more technical and advanced work the commission believes that distinctive industrial schools, separated entirely from the public school system, should be maintained. This departure is held to be entirely in accord with the policy to which the State is already fully committed

through its support of normal schools, art schools, institutes of technology, and the agricultural college. In order to secure proper instruction for teachers in the elements of agriculture, it is suggested that a normal department be established in the State agricultural college, instead of attempting to introduce the subject into normal schools or establish a separate school for that purpose.

The recommendations of this commission are embodied in a bill submitted to the legislature, which provides for the appointment of a commission on industrial education to promote this work, and proposes State aid to towns and cities for the maintenance of distinctive schools for industrial training, or of industrial courses in high or manual training schools. The hearings on this bill before the legislative committees have attracted much attention, and developed widespread interest in favor of the measure.

The notable progress which has recently been made in the development of commercially successful methods of fixing the free nitrogen of the air, and thus making it available for agricultural and other industrial purposes, should go far toward reassuring those who are disposed to view with alarm the rapid exhaustion of the world's principal known supply of combined nitrogen, namely, the nitrate deposits.

The rapidly increasing demand (which has risen from less than 200,000 tons of nitrate in 1870 to over 1,500,000 tons in 1905) and the steadily diminishing supply have stimulated unusual activity in efforts to apply the discoveries of science to the solution of the great industrial problem of finding a practical means of maintaining a cheap and reliable supply of fixed nitrogen.

The encouraging results yielded by the Frank and Caro calcium cyanamid process have already been referred to (E. S. R., 15, p. 423). Further developments in the application of this process have fully justified the promise of the earlier trials, and factories have been built in Italy, Germany, and elsewhere to test the process on an extensive commercial basis. The numerous experiments which have been made to test the fertilizing value of the so-called lime nitrogen (*Kalkstickstoff*) prepared by this process indicate that when used with proper precautions and under certain restrictions the product has a fertilizing value in general but slightly inferior to that of nitrate of soda and somewhat superior to that of sulphate of ammonia. The results of hundreds of such experiments on a great variety of soils and crops are given in a recent 120-page report issued at Rome, which is briefly noted elsewhere.

Improvements are constantly being made which increase the efficiency of the process and lessen the cost of the product, and which encourage the belief that where cheap water power is available this

process can be made to yield a product capable of competing successfully with nitrate of soda in the markets of the world.

The most recent and most notable development in the line of fixation of the nitrogen of the air for commercial purposes is, however, in the nature of a return to the earlier methods of direct oxidation by means of electric discharges. Prof. K. Birkeland, of the University of Christiania, Norway, and S. Eyde, a Norwegian civil engineer, have devised a process for greatly increasing the size and efficiency of the ordinary electric arc, so that oxidation of the nitrogen is more rapid and is accomplished with much less expenditure of electric energy, and hence at less cost than in preceding processes.

A recent writer in describing the process says: "The inventors, instead of working with arcs of the lowest possible amperage, make the first technical application of a phenomenon previously known to physicists, the action of the magnetic field on the arc." They use a powerful current of electricity in the form of great glowing electric disks, up to 6 feet in diameter, which are built up of arcs deflected by powerful magnets.

By means of powerful electromagnets placed vertically to the electrodes, which are hollow and cooled with a stream of water, "the arc formed between the electrodes is blown away, as it were, by the influence of the magnetic field, and at once a new arc is formed, which is blown away. This process can be repeated 1,000 times a second, though in practice only a few hundred arcs per second are used. With alternating current arcs and direct current magnetic field, or vice versa, the arcs vibrate between the electrodes as circular disks." There is thus secured the alternate heating (to 2,000° C.) and cooling, and the rapid and thorough contact of the air with the most active zone of the arc, which are essential to the highest oxidation efficiency.

The efficiency of this process has been demonstrated in an experimental factory near Notodden, Norway, which utilizes the unusually cheap water power of that region for the production of the electrical energy required. It is reported that the daily output of this factory for the year during which it has been in operation is about 3,300 pounds of pure nitric acid, and the factory has been pronounced a technical and financial success by the eminent authority, Otto N. Witt, of Berlin. The success of the experimental factory has been such that several larger establishments are being built at other places in south Norway where cheap water power can be had. It is claimed that these factories will utilize in the aggregate about 30,000 horsepower, and that the company exploiting the patent has options on Norwegian waterfalls capable of yielding 350,000 horsepower at very low cost.

It is reported that nitric acid can be produced by this process at less than one-tenth of its present cost. Owing, however, to the dilution of the products of oxidation the difficulty and expense is less in

production than in concentration of the nitric acid. The latter has not yet found a perfect technical solution, and so it has been found most economical to market the product in form of calcium nitrate.

For agricultural purposes especially the calcium nitrate is mixed with an excess of lime, yielding a dry, easily handled material known commercially as "lime niter" (*Kalksalpeter*), which contains on an average 8 to 9 per cent of nitrogen and about 22 per cent of lime. A number of experiments have been made with this material which indicate that it has a fertilizing value slightly superior to nitrate of soda on soils benefited by lime as well as nitrogen.

In a recent article reviewing two important contributions to the subject of fixation of atmospheric nitrogen, E. Renouf enumerates and discusses the relative efficiency of no less than four distinct methods of accomplishing this result, viz, fixation by means of micro-organisms, formation and decomposition of nitrids, the production of calcium cyanamid, and electrical oxidation; and expresses the conviction that "by the time the Chili saltpeter beds are exhausted chemists and engineers will be ready with practical and economic methods of utilizing atmospheric nitrogen to meet the demands of agriculture and industry."

The products of the various processes for fixing the nitrogen of the air have not yet found their way into markets in sufficient quantity to establish their commercial rating, but Prof. Silvanus P. Thompson, the eminent English physicist, in a recent lecture before the Royal Institution of London, asserts his belief that where conditions are exceptionally good for the furnishing of power at exceedingly low rates, nitrogen compounds can be prepared by the Birkeland and Eyde process at a price which will enable them to compete with nitrate of soda in the market, becoming every year more valuable as the demand for nitrates increases and the natural supply becomes exhausted.

The development of these methods, while of great practical importance, is also of the highest significance as an illustration of the successful application of the results of investigations in pure science to practical affairs and commercial needs. The working out of these methods on a practical basis is rendered possible only because of the long series of scientific investigations beginning with Cavendish and continued by his successors in similar lines of work, which were undertaken solely for the purpose of advancing chemistry and physics as pure sciences and with no thought of practical results or commercial rewards.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

The permanent committee on the analysis and control of agricultural products, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 11 (1906), No. 4, pp. 101, 102*).—The duties of this committee, consisting of 32 members (including some of the most eminent scientific men of France), appointed by the minister of agriculture December 15, 1905, under the provision of a law of France of August 1, 1905, for the repression of fraud in foods, feeding stuffs, seeds, fertilizers, and agricultural products in general, are explained.[a] The committee has organized into a number of subcommittees for the consideration of different phases of its work.

Methods of analysis of fertilizers in different countries, L. SICARD (*Ann. École Nat. Agr. Montpellier, n. ser., 5 (1906), No. 3, pp. 204–222*).—This is the third report on this subject, and deals with methods of determining potash, describing the various methods which have been proposed for this purpose. The decisions of the Fifth International Congress of Applied Chemistry with relation to the analysis of nitrates are also given.

On the importance of uniform international methods of analysis, H. NISSENSON (*Chem. Ztg., 30 (1906), No. 3, pp. 16, 17*).—A number of illustrations of the need of such methods are cited.

New method for the determination of atmospheric carbon dioxid, based on the rate of its absorption by a free surface of a solution of an alkali hydroxid, H. T. BROWN and F. ESCOMBE (*Proc. Roy. Soc. [London], Ser. B, 76 (1905), No. B507, pp. 112–117; abs. in Jour. Chem. Soc. [London], 88 (1905), No. 518, II, p. 858*).—The method proposed is based upon the fact that when a current of air containing a constant proportion of carbon dioxid is drawn over the free surface of a solution of sodium hydroxid the rate of absorption increases with the velocity of the current up to a certain point, beyond which it remains constant. Furthermore, the rate of absorption is proportional to the partial pressure of the carbon dioxid within fairly wide limits.

In the method described the air is aspirated through the apparatus at a rate greater than that required for maximum absorption, and being drawn through a perforated plate is made to impinge in a turbulent stream on the surface of a standardized solution of sodium hydroxid, which is titrated after the experiment. A constant for the apparatus having been determined in a preliminary experiment, in which the air is measured, the proportion of carbon dioxid in a

[a] For composition and duties of this commission and the law under which it was appointed, see also Jour. Agr. Prat., n. ser., 10 (1905), Nos. 32, p. 181; 52, p. 805.

sample of air can be calculated from the time during which the current has passed and the amount of gas absorbed, a correction being applied for the effect of change of temperature on the rate of absorption.

On the determination of carbon monoxid in the air by means of iodin anhybrid, ALBERT-LÉVY and A. PÉCOUL (*Compt. Rend. Acad. Sci.* [*Paris*], *142* (*1906*), *No. 3, p. 162; abs. in Rev. Sci.* [*Paris*], *5. ser., 5* (*1906*), *No. 4, p. 112*).—In the method proposed use is made of the fact that one part of carbon monoxid in 10,000,000 of air gives an intense coloration in chloroform containing the anhydrid as a result of the liberation of iodin. Acetylene of the same strength gives no coloration.

The determination of sulphuric acid in drinking water, F. RASCHIG (*Ztschr. Angew. Chem., 19* (*1906*), *No. 8, p. 334*).—In the method proposed ½ liter to 5 liters of water, according to the sulphuric acid content, is mixed with the twentieth part of its volume of concentrated benzidin solution, stirred, and allowed to stand 15 minutes. If no precipitate is formed, the water contains 1.5 mg. of sulphuric acid (SO_3) or less. If a precipitate forms, it is collected on a filter, washed, and titrated in the usual way with tenth-normal sodium hydroxid. One cc. of the hydroxid corresponds to 4 mg. of SO_3. A correction of 1.5 mg. must be added in each determination.

Field assay of water, M. O. LEIGHTON (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 151, pp. 77, pls. 4, figs. 3*).—This paper describes and discusses methods which have for some time been successfully used in investigations carried on by the division of hydro-economics of the U. S. Geological Survey on the quality of water in various parts of the United States.

Methods of determining turbidity, color, total hardness, alkalinity, normal carbonates, bicarbonates, total sulphates, chlorin, or total chlorids, iron, and calcium are discussed. Only such methods are described as are considered necessary for the determination of the ingredients which give waters their essential characteristics, and these are confined to simple and cheap methods useful for practical purposes and easily carried out in the field, but of little or no value from a purely scientific standpoint.

On the theory of the formation of potash deposits from sea water, E. JÄNECKE (*Ztschr. Angew. Chem., 19* (*1906*), *No. 1, pp. 7–14, figs. 8*).—A discussion of the physico-chemical theory of the formation of oceanic salt deposits as enunciated by Van't Hoff.

Colorimetric, turbidity, and titration methods used in soil investigations, O. SCHREINER and G. H. FAILYER (*U. S. Dept. Agr., Bur. Soils Bul. 31, pp. 60, pl. 1, figs. 5*).—The methods which have been used in the investigations of the Bureau of Soils and others which are applicable to similar work are concisely described in this bulletin "for the convenience of those desirous of continuing these investigations or of carrying on new lines of inquiry."

After a preliminary explanation of methods of preparing solutions from moist and dry soils, the construction and operation of the Briggs filtering apparatus (E. S. R., 14, p. 126), the decolorizing of soil solutions, the use of centrifugal and other methods of obtaining soil solutions devised by Briggs, McLane, and McCall (E. S. R., 16, p. 450), the preparation and decolorization of solutions from green and dried plants, the general principles and purposes of colorimetric, turbidity, and titration methods, and the construction and use of colorimeters, especially that of Schreiner,[a] the authors describe in detail the following methods: Colorimetric methods—ammonium, Nessler; potassium, Cameron and Failyer (E. S. R., 15, p. 444) and Hill (E. S. R., 15, p. 224);

[a] Jour. Amer. Chem. Soc., 27 (1905), pp. 1192–1203.

magnesium, Schreiner and Ferris;[a] manganese, Clennell; iron, Thomson's, as described by Sutton; titanium, Weller; nitrate, Gill (E. S. R., 6, p. 189); nitrite, Hosvay's modification of Griess's test; phosphate, Schreiner and Brown (E. S. R., 16, p. 533), and Woodman and Cayvan and Veitch (E. S. R., 13, p. 319; 14, pp. 125, 833); silica, Veitch and Schreiner (E. S. R., 14, p. 833; 15, p. 444); silica and phosphate combined, Schreiner (E. S. R., 15, p. 444); sulphate and sulphid, Winkler;[b] turbidity methods—calcium, Ferris's modification of Hinds (E. S. R., 8, p. 286); sulphate, Belz's modification of Hinds and Jackson; chlorid, Richards and Wells;[c] titration methods—calcium and magnesium, Winkler's modification of Clarke's soap method;[d] carbonate and bicarbonate, Cameron (E. S. R., 13, p. 428); chlorid, the standard silver nitrate and potassium chromate method.

On the determination of nitric acid in soils, BUHLERT and FICKENDEY (*Landw. Vers. Stat., 63 (1905), No. 3-4, pp. 239-246*).—The following method, based upon the results of studies of various factors affecting the accuracy of the determination of nitric acid in soils, is proposed:

Two kg. of the fresh sample of soil taken from a large number of places in a field and thoroughly mixed is shaken up immediately with 2 to 3 liters of water, shaking for ½ minute at intervals of 5 minutes. At the end of not more than 30 minutes the solution is allowed to settle somewhat and is filtered through a folded filter. Four hundred to 500 cc. of the filtrate is evaporated with the addition of a few drops of sodium hydroxid solution and analyzed by the Schloesing method. Very cloudy solutions are cleared by addition of 2 per cent sodium chlorid solution.

On the determination of aluminum, H. WEBER (*Ztschr. Analyt. Chem., 44 (1905), No. 12, pp. 769-776*).—This is a review of recent literature relating to this subject.

Examination of foods, condiments, and commercial products, M. MANSFELD (*Die Untersuchung der Nahrungs- und Genussmittel sowie einiger Gebrauchsgegenstände. Leipsic and Vienna: Franz Deuticke, 1905, pp. XV+243, figs. 35; rev. in Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 12, pp. 766, 767*).—In this, the second edition, chapters on meat products and compressed yeast have been added and the whole book has been revised.

The proportion of glutaminic acid yielded by various vegetable proteins when decomposed by boiling with hydrochloric acid, T. B. OSBORNE and R. D. GILBERT (*Amer. Jour. Physiol., 15 (1906), No. 4, pp. 333-356*).—The proteids studied were obtained from cereals, legumes, oil-bearing seeds, and meat, fish, milk, and eggs.

In the case of the vegetable proteids the smallest amount of glutaminic acid 5.72 per cent, was obtained from the leucosin of wheat and the largest amount, 37.17 per cent, from the gliadin of wheat. "The proteins of the cereals yield much more glutaminic acid than do any of the other groups, for, omitting leucosin, which is present in the wheat kernel only in very small proportion and confined chiefly to the embryo of the seed, the average yield of this acid was 29.5 per cent, while the legumes yielded 19.6 per cent, the oil seeds 16.8 per cent, and the 3 animal proteins 8.9 per cent. . . . It would appear that such animal proteins as have been carefully investigated yield similar proportions of glutaminic acid, namely, about 8 to 11 per cent.

---

[a] Jour. Amer. Chem. Soc., 20 (1904), pp. 961-967.
[b] Ztschr. Anal. Chem., 40 (1901), pp. 465, 772.
[c] Jour. Amer. Chem. Soc., 27 (1905), p. 459.
[d] Ztschr. Anal. Chem., 40 (1901), p. 82.

"In view of the wide differences in the constitution of the proteins of the different species of seeds, as shown by the determinations of glutaminic acid given in this paper, as well as by the few quantitative determinations of the other decomposition products which have been made, it would seem important to know definitely whether or not similar differences exist between the proteins of the tissues of different species of animals which serve as food for man, for it is possible that in such differences will be found a logical basis for the use of one form of protein rather than another when dealing with nutrition in various pathological conditions."

The authors propose to continue their investigations.

Concerning the detection of boric acid, G. Fendler (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 3, pp. 137–144*).—A method of estimating boric acid is described which depends upon comparing the intensity of the curcuma paper reaction with a color scale made by immersing strips of curcuma paper for different lengths of time in different solutions of boric acid of known strength.

The sensitiveness of curcuma paper for boric acid reaction, L. Wolfrum and J. Pinnow (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 3, pp. 144–154*).—Different sorts of commercial curcuma paper were compared.

The estimation of sulphurous acid in certain foods and also the estimation of sulphur in illuminating gas, T. Schumacher and E. Feder (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 11, pp. 649–659, fig. 1*).—The method described depends upon the distillation of an acidulated portion of the substance to be examined with a solution of iodate of potassium.

The detection of talc and coloring matter in grits and rice, E. von Raumer (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 12, pp. 744–746*).—It has been found that coloring matters and talc are easily separated with chloroform. The author describes a method of estimating talc which depends upon shaking the sample with chloroform and evaporating to dryness.

The occurrence of cholesterin and lecithin in milk and their importance in the determination of fat by the Gottlieb method, M. Siegfeld (*Milchw. Zentbl., 2 (1906), No. 1, pp. 1–5*).—Fat determinations by the Gottlieb method were found to be 0.0243 per cent too high, due to the presence of 0.0041 per cent of ether-insoluble material, 0.0036 per cent of unsaponifiable material, and 0.0166 per cent of lecithin in the solids obtained by this method.

On the accuracy of the Wollny refractometer, the Gottlieb method, and the Gerber acid butyrometer for the determination of fat, H. Schrott-Fiechtl (*Milchw. Zentbl., 2 (1906), No. 1, pp. 13–19*).—The Gottlieb-Röse method is considered the most accurate gravimetric method for the determination of fat in milk. The average of 100 determinations by this method was 2.2849 per cent and by the refractometer method 2.2755 per cent. A similar comparison of the Gerber and Wollny methods gave average results of 3.7252 and 3.7210 per cent, respectively.

New nonacid method for the rapid determination of fat in milk, N. Gerber (*Milch Ztg., 35 (1906), No. 4, pp. 37, 38*).—Comparative tests of the Sichler and Gerber methods are reported and the conclusion is drawn that there is no reason for abandoning the Gerber method in favor of the nonacid method.

Formalin as a means of preventing plugging in the determination of fat in the Gerber butyrometer, C. Beger, (*Milchw. Zentbl., 2 (1906), No. 1, pp. 6–8*).—This trouble, according to the author, may be avoided by the addition of 1 drop of formalin per cubic centimeter of amyl alcohol and the accuracy of the test not interfered with.

The determination of the fat content of butter, H. Lührig (*Molk. Ztg., 19 (1905), No. 48, pp. 1217, 1218*).—The author tested the method of E. Von Waegenigh.

In this 1 gm. of butter is shaken with 20 cc. of ether, and 0.5 gm. of powdered tragacanth and 2.5 cc. of water are added to the mixture, which is then centrifuged for 2 to 3 minutes. The ether layer containing the fat is separated, the ether evaporated, and the fat weighed. The tragacanth is added for the purpose of removing the water, proteids, milk sugar, and salt from the fat. The method was found to be rapid, but not very accurate. It is considered worthy of further study.

New method for the detection of cocoanut oil in butter, U. P. Wijsman and Reijst (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 5, pp. 267–271; Rev. Soc. Sci. Hyg. Aliment., 2 (1905), No. 5, pp. 491–498*).—This method is based upon the precipitation of volatile fatty acids by silver nitrate.

To the filtered and neutralized distillate obtained in the Reichert-Meissl method is added 40 cc. ot a decinormal solution of silver nitrate. This is filtered and the precipitate washed until about 200 cc. of liquid is obtained, to which is added 50 cc. of decinormal solution of sodium chlorid. The excess of sodium chlorid is determined by titration with decinormal silver nitrate, potassium chromate being used as an indicator. The difference between the total number of cubic centimeters of silver nitrate employed and the number of cubic centimeters of sodium chlorid increased by 0.1 is called the first silver index.

A second silver index is obtained by using 300 cc. of distillate from the Reichert-Meissl method instead of 110, adding 40 cc. of a decinormal silver nitrate to 250 cc of this liquid, filtering and washing until 350 cc. of liquid is obtained. The number obtained as above is increased by one-fifth. The presence of cocoanut oil is indicated by an increase in the second silver index over the first.

On the value of Schiff's reagent for the detection of formaldehyde in milk, Utz (*Milchw. Zentbl., 2 (1906), No. 1, pp. 12, 13*).—The author concludes, as the result of his investigations, that this reagent is not to be recommended for the detection of formaldehyde in milk, and that the best method for this purpose is that of Arnold and Mentzel (E. S. R., 13, p. 1015).

The relation of cows' milk to Schiff's reagent and a test for formalin in milk, Eichholz (*Milchw. Zentbl., 1 (1905), No. 11, pp. 499, 500*).—This is a criticism of the article by Seligmann previously noted (E. S. R., 16, p. 742).

Separation of nitrogenous bodies in cheese, R. Harcourt (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 70–76*).—This report was presented at the last meeting of the Association of Official Agricultural Chemists (E. S. R., 17, p. 432).

Extracts from the proceedings of the Association of Official Agricultural Chemists, 1905, edited by H. W. Wiley (*U. S. Dept. Agr., Bur. Chem. Circ. 26, pp. 16*).—This gives the recommendations of referees as adopted, motions, and appointments affecting the work of the association for 1906. A summarized account of the proceedings of this association in 1905 was given in a previous number of the Record (E. S. R., 17, p. 423).

Agricultural chemistry, A. Morgen and W. Zielstorff (*Jahrb. Chem., 14 (1904), pp. 286–303*).—This is a brief review of progress during 1904 in investigations relating to air and water, soils, fertilizers, plant physiology, and animal physiology, including also biographical and miscellaneous notes.

Text-book of meteorology, J. HANN (*Lehrbuch der Meteorologie. Leipsic: H. Tauchnitz, 1905, 2. ed., pp. 642; rev. in Nature* [*London*], *73* (*1906*), *No. 1890, p. 270*).—The first edition of this work appeared in 1901 (E. S. R., 13, p. 923). In this second edition the volume of the book has been considerably reduced, many original references cut out and new ones added, and many parts thoroughly revised, as, for example, the section relating to meteorology of the upper air.

The study of meteorology, F. WALDO (*Education, 26* (*1905*), *No. 3, pp. 149–153*).—This is a brief review of progress which has been made in the United States in developing courses of instruction in meteorology, especially the work of Professor Davis at Harvard. The courses in meteorology given at that institution are described, as well as the opportunities for advanced work at the Harvard College Astronomical and Blue Hill observatories.

Recent advances in meteorology and meteorological service in Japan, S. T. TAMURA (*Pop. Sci. Mo., 68* (*1906*), *No. 2, pp. 139–144*).—A brief account is given of the organization, equipment, and work of the meteorological service of Japan, which was established in 1875, systematic meteorological observations having been made, however, as early as 1872 at the observatory at Hakodaté. The important contributions which Japanese meteorologists have made to practical and theoretical meteorology and the diffusion of such knowledge are considered in some detail.

Weather report, 1905, J. B. REYNOLDS (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31* (*1905*), *pp. 32, 33*).—Tabular statements are given of observations at Ontario Agricultural College and at various other points in Ontario on temperature and precipitation. The temperature and frost observations at Guelph during 1905 are compared with those of 6 preceding years. The mean temperature for 1905 was 43.6° F., the highest 89.06, in July, the lowest —15, in February; the last killing frost in spring April 24 (29.5°), the first in autumn September 26 (29°).

Meteorological observations, J. E. OSTRANDER, C. H. CHADWICK, and T. A. BARRY (*Massachusetts Sta. Met. Buls. 205, 206, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during January and February, 1906. The data are briefly discussed in a general note on the weather of each month.

Report of meteorologist, N. HELME (*Rhode Island Sta. Rpt. 1905, pp. 327–343*).—This includes general notes on the weather during the year ended June 30, 1905, and a tabulated record of observations at Kingston on temperature, precipitation, cloudiness, and prevailing winds during each month from July, 1904, to June, 1905, inclusive, with a summary for the year ended June 30, 1905. The latter summary is as follows:

Temperature (degrees F.).—Maximum, 87, July 19, 1904; minimum, —4, February 4, 1905; mean, 45.3; highest monthly mean, 68.3, July, 1904; lowest monthly mean, 21, February, 1905; highest daily mean, 75, July 19 and 20, 1904; lowest daily mean, 7.5, February 4, 1905. *Precipitation* (inches).—Total (rain and melted snow), 41.64; greatest monthly, 7.63, August, 1904; least monthly, 1.69, May, 1905; greatest in 24 consecutive hours, 2.48, August 10, 1904; snowfall, total 51. *Weather*.—Number of clear days, 151; number of fair days, 122; number of cloudy days, 92; number of days on which there was precipitation of 0.01 in. or more, 99. *Prevailing wind*, southwest and west.

Meteorological data, H. L. PRICE (*Virginia Sta. Bul. 155, pp. 119–129, charts 5*).—A previous bulletin of the station (E. S. R., 11, p. 128) gave summaries of observations on temperature, precipitation, wind, cloudiness, etc., for the period 1893–1898, and charts showing variation in temperature and rainfall for the same period. This bulletin brings these observations and charts down to the end of 1904. The following summary for the period 1893–1904 is given:

"*Temperature.*—Mean annual, 51.5°; mean maximum, 63.22°; mean minimum, 40.04°; absolute maximum, 96°; absolute minimum, —13°. Dates when temperature fell to or below zero: January 10, 11, 15 and 16, 1893; December 29, 1894; January 12 and 13 and February 3, 6, 7, 8, 9 and 15, 1895; February 20 and 21, 1896; January 28 and 30, 1897; February 3 and 4, 1898; February 1, 9, 10, 11, 13 and 14, and December 31, 1899; February 1, and March 17 and 18, 1900; December 16 and 21, 1901; February 19, 1903; January 30 and February 6, 1904. Dates when maximum temperature rose to or above 95°: August 10 and 11 and September 3 and 10, 1900; July 17, 1902.

"*Precipitation.*—Mean annual, 39.41 inches; spring, 10.22; summer, 12.57; fall, 7.50; winter, 9.12. Highest for month, August, 1901, 10.53; lowest for month, October, 1904, 0.13. Greatest depth of snow in 24 hours: 11 inches, January 9, 1895.

"*Frost.*—Average date of last killing frost in spring, April 25; average date of first killing frost in fall, September 30; date of latest killing frost recorded, May 13, 1895; date of earliest killing frost recorded, September 22, 1897."

Observations on the intensity and duration of rainfall, A. WOEIKOF (*Met. Ztschr., 23 (1906), No. 1, pp. 8–10*).—Four rainfall types are briefly described.

Rainfall per day and hour in Northwest England, A. WOEIKOF (*Met. Ztschr., 23 (1906), No. 1, pp. 6–8*).

Distribution of summer rains in Germany, E. LESS (*Met. Ztschr., 22 (1905), Nos. 11, pp. 496–505, figs. 4; 12, pp. 529–547, fig. 1*).—Rainfall movements are traced and the conditions (temperature, pressure, etc.) affecting them are discussed.

Estimation of the possible period of sunshine and its normal value for Germany, GROSSMANN (*Met. Ztschr., 22 (1905), No. 10, pp. 433–438*).

The relation of the temperature of the lowest layers of the air to that of the upper layers containing solid and liquid matter, A. WOEIKOF (*Met. Ztschr., 23 (1906), No. 1, pp. 1–6*).

Daily temperature periods in the lowest layer of the air, M. SASSENFELD (*Met. Ztschr., 23 (1906), No. 1, pp. 24–30*).—The periods are worked out for normal, clear, and cloudy days on the basis of observations at Potsdam.

On the importance of drainage for the elimination of danger from frost, L. LINDELÖF ET AL. (*Svenska Mosskulturför. Tidskr., 19 (1905), No. 5–6, pp. 495–513*).—A discussion of the subject by a committee of scientists appointed by the Finnish State Board of Agriculture.—F. W. WOLL.

International catalogue of scientific literature. F—Meteorology (*Internat. Cat. Sci. Lit., 3 (1905), Oct., pp. VIII+235*).—This is the third annual issue of this catalogue. The literature indexed is mainly that of 1903 and of the earlier part of 1904.

Lightning report, J. B. REYNOLDS (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 30–32*).—A statement is given of destruction and damage by lightning in Ontario during 1905 as compared with previous years. The data are tabulated with reference to trees, animals, and buildings struck.

Geology and water resources of Oklahoma, C. N. GOULD (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 148, pp. 178, pls. 22, figs. 32*).—This

paper deals with topography, geology, water supply (streams, springs, deep wells, and artesian wells), irrigation, climate, and water analyses. The water conditions of each county are separately discussed, and records of 10 wells from each of the 26 counties in the State are given.

Preliminary list of deep borings in the United States, N. H. DARTON (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 149, 2. ed., pp. 175+III*).—A table of borings more than 400 ft. in depth, giving location, depth, diameter, yield per minute, and height of water, with additional data where available, together with bibliographies of the subject by States.

Purification of waters for industrial purposes, D. PENIAKOFF (*Bul. Soc. Chim. Belg., 19 (1905), Nos. 5, pp. 122–136; 6, pp. 159–171*).—The author discusses in some detail and reports a large number of tests of the various chemical precipitation methods which have been proposed for this purpose. The results indicate that on the whole the use of aluminate of barium (Al_2BaO_4) gives the most satisfactory results.

The sterilization of water by means of ozone, E. PILATTE (*Rev. Sci. [Paris], 5. ser., 5 (1906), No. 2, pp. 37–43*).—This is an account of the application of Otto's method (E. S. R., 17, p. 642) to the water supply of Nice. It is claimed that the method gave satisfactory results and there appears to be no reason why the total water supply of the city, amounting to 22,500 cubic meters daily, should not be efficiently treated by the process.

Notes on water softening, W. M. GARDNER and L. L. LLOYD (*Jour. Soc. Chem. Indus., 24 (1905), No. 8, pp. 392–395; abs. in Engin. and Min. Jour., 80 (1905), No. 22, pp. 1021, 1022*).—This article deals with the influence on the softening process of the amount of neutral salts present and the method and apparatus used in carrying out the process.

It is claimed that the neutral salts always present to a more or less extent in water are more deleterious than is generally recognized, and their proportion may be notably increased by the use of sodium carbonate to remove hardness due to calcium. The influence of apparatus depends mainly upon the time allowed for the reactions to proceed and upon temperature as well as thoroughness of mixing. The Pfeifer and Wartha formulas for determining the amounts of reagents to be used in softening water (E. S. R., 15, p. 746) are considered unreliable when much neutral salts is present. The authors prefer to base the treatment upon direct determination of the lime and soda present. Methods of doing this are described.

The use of barium hydroxid as a softening reagent is referred to and the opinion is expressed that at its present price this material can be used only in special cases, and since barium compounds are reputed to be poisonous, it is obvious that the barium hydroxid should be used with great caution in the treatment of drinking water. "If the amount used is carefully regulated, however, to exclude the possibility of the presence of barium carbonate, not a trace of barium remains in solution."

Hints on water supply (*Jour. Bd. Agr. [London], 12 (1905), No. 3, pp. 144–149*).—Suggestions are made in this article regarding the development of underground supplies of water, especially in time of drought. The measurement of the flow of springs and streams is also described and means of filtering and purifying the water of surface streams and of collecting rain water are explained, as well as a method of calculating the available supply of wells.

The sanitary protection of water supplies, K. ALLEN (*Jour. Franklin Inst., 160 (1905), No. 4, pp. 297–323*).—In this paper it is pointed out that unsanitary conditions may be detected by analysis of the water, by inspection of watersheds, or by mortality statistics.

Knowledge of the life history of the typhoid germ and registration of vital statistics are important, and presumptive tests for *Bacillus coli communis* are considered valuable. In the author's opinion corrective treatment may be applied by the individual but should be applied to the entire supply. It may consist in (1) prevention of pollution, (2) adoption of a pure supply, (3) purification of an inferior supply. Control by boards of health, with Federal control as a last resort, is suggested. In any case ample power and funds should be provided.

In selecting method of securing pure water with limited resources it is inadvisable to strive for ideal results in some detail at expense of greater general benefit.

The sanitary value of a water analysis, L. P. KINNICUTT (*Science, n. ser., 23 (1906), No. 576, pp. 56–66*).—The substance of this paper has been noted from another source (E. S. R., 17, p. 611).

On the detection of fecal contamination of drinking water, CHRISTIAN (*Arch. Hyg., 54 (1905), No. 4, pp. 386–395*).—After briefly reviewing the literature bearing directly upon this subject, the author reports tests of Eijkmann's method,[a] which is based upon the ability of colon bacilli to grow at 46° C. By varying the temperature it was found that certain organisms of the coli groups derived from cold-blooded animals were active at 37° but not at 46°. In case of the organisms derived from warm-blooded animals, however, there was growth at 46° C.

Sewerage and sewage purification, M. N. BAKER (*New York: D. Van Nostrand Co., 1905; rev. in Jour. Amer. Chem. Soc., 27 (1905), No. 12, p. 1573*).—This is a second edition of this book, which was first published in 1895. The part which treats of sewage purification has been almost entirely rewritten and embodies the advances in methods which have been made in this country and in England in recent years, including discussions of treatment of sewage by intermittent filtration beds, septic tanks, contact beds, and percolating filters.

A review of the laws forbidding pollution of inland waters in the United States, E. B. GOODELL (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 152, pp. 149*).—This is a second revised edition of Water-Supply and Irrigation Paper No. 103 (E. S. R., 16, p. 721).

SOILS—FERTILIZERS.

Treatise on soils for farmers and foresters, E. A. MITSCHERLICH (*Bodenkunde fur Land- und Forstwirte. Berlin: Paul Parey, 1905, pp. VIII+364, figs. 38*).—This book treats the subject of soils, as they occur in nature, solely from the physical and chemical standpoints without reference to geological origin or previous history, the author taking the position that the only connecting link between geological and physiological soil knowledge is that furnished by the fundamental sciences—physics and chemistry.

Accordingly, after a brief introduction defining the word soil and discussing the value of soils and the purpose of soil investigation, the book proceeds at once to the consideration of (1) the physical nature of soil samples, (2) the chemical nature of soil samples, and (3) soils in place.

The first part includes specific characteristic of the solid soil particles, the relation of these particles to one another and to the volume of space in soil, soil water and its relation to the solid soil particles, soil atmosphere and its relation to soil water and to the solid soil particles, and the relation of soils to heat.

[a] Centbl. Bakt. [etc.], 1. Abt., Orig., 37 (1904), No. 5, p. 742.

The second part discusses the general chemical properties of soils and chemical analysis of soils. The third part deals with the properties of soils in place and their variation under natural conditions, and classification of soils.

The attempt has been made to incorporate in the treatise the more important results of previous investigations (mainly German and French) on the physics and chemistry of soils, including those of the author, especially the application of his method of determining the heat generated when soils are moistened (*Benetzungswärme*) in the study of the physical properties of soils (E. S. R., 13, p. 833; 14, p. 127; 17, p. 745).

Classification and nomenclature of cultivated soils, H. LAGATU (*Ann. École Nat. Agr. Montpellier, n. ser., 5 (1906), No. 3, pp. 193–204, figs. 3*).—This article consists of reprints of 3 shorter articles which have already been noted from another source (E. S. R., 17, pp. 113, 226).

The soil survey of Illinois, C. H. OATHOUT (*Ill. Agr., 10 (1905), No. 4, pp. 105–107*).—A brief account is given of the soil survey of the State, begun in cooperation with the Bureau of Soils of this Department and recently continued independently by the station. The methods pursued in making surveys, collecting and examining the samples, and in testing typical areas by means of plat experiments are described.

Soils of the Bahama Islands, C. N. MOONEY (*Separate from The Bahama Islands. New York and London: The Macmillan Co., 1905, pp. 147–181, pls. 8*).—This is an account of a reconnaissance and survey of the soils of these islands under the auspices of the Geographical Society of Baltimore. "The area surveyed and mapped amounted in all to about 700 square miles, and included five islands and a few small cays, viz: New Providence, Eleuthera, Cat, Long and Watlings islands, and Rum Cay and the cays adjacent to New Providence and Eleuthera."

The report discusses the agricultural development, climate, geology, soil types, methods of cultivating and cropping, and important crop and soil problems.

"As the geological formation and physiographic features of all the islands are the same, a great diversity of soil types is not found. In all 7 types of soil are recognized, as follows: Coral sands, Bahama black loam, Bahama sandy loam, Bahama red loam, Bahama marl, brackish swamp, and Bahama white marl." These 7 types are described in detail. Accompanying the descriptions of each type are mechanical analyses made by the method of the Bureau of Soils of this Department and chemical analyses made by the methods of the Association of Official Agricultural Chemists. Analyses of the water-soluble salts by methods proposed by the Bureau of Soils are also given.

With the exception of the coral sand, which occupies a narrow strip along the coast, the soils of the islands are generally of a rocky character, underlaid at a variable but generally slight depth by coralline limestone. The Bahama black loam, which is known as "provision land," and varies from a loose brown to a jet black loam consisting of rounded grains of coral sand with a large percentage of organic matter, is the principal type on the islands, occupying approximately three-fourths of their area. The soils as a rule are well supplied with plant food, in many cases being very rich. The agriculture of the islands, however, is in a depressed condition.

The soils of the Rhenish Palatinate and their relation to geological formations, E. BLANCK (*Vrtljschr. Bayer. Landw. Rat., 10 (1905), No. 3, pp. 419–447*).—The mineralogical and chemical properties of the rocks from which these soils are derived and the varying characteristics of the soils derived from their disintegration are discussed, the chemistry of the weathering processes receiving especial attention.

The soil of Gascony, L. A. FABRE (*Géographie, 11 (1905), Nos. 4, pp. 257–284, figs. 6; 5, pp. 343–358, figs. 3; 6, pp. 413–434, figs. 3*).—This deals with topography, geological origin and formations, the Gascon régime (including meteorology, etc.), geographical conditions, morphological evolution, coal deposits and their physiological relations, and economic and sociological conclusions with reference to the protection of the mountain soils.

Some observations on humus soils, G. SALOMONE (*Staz. Sper. Agr. Ital., 38 (1905), No. 7–8, pp. 696–704; abs. in Chem. Centbl., 1905, II, No. 26, p. 1819*).—The formation of humus out of plant remains is described and the composition of humus soils made with leaves of various kinds of trees is given.

Marsh soils, F. SCHUCHT (*Jour. Landw., 53 (1905), No. 4, pp. 309–328; abs. in Chem. Centbl., 1906, I, No. 1, p. 71*).—The results are given of mechanical and chemical studies of a large number of marsh soils with reference to the present character and the changes which the soils have undergone under the influence of weathering. The conclusion is reached that calcium carbonate is the constituent of marsh soils which gives the most reliable indication of the stage of weathering which the soils have undergone. It is possible by means of a study of the extent to which this constituent has been removed to approximate the geological age of the marsh.

Swamp soils, R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 82–86*).—This is a brief discussion of the origin and properties of such soils based upon investigations carried on by the author during the past 3 years.

The effect of different soils upon the composition of crops, W. P. GAMBLE (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 93–100*).—The ash constituents of oats grown in pots filled with surface soil and under normal conditions on a field plat are compared, and the results are summarized as follows:

"(1) The largest percentage of mineral constituents (ash) was found in the oats grown upon the surface soil. Two reasons are given for this increase—(*a*) the supply of moisture was perhaps more uniform with the pot-grown plants, and (*b*) the soil in the cans was freely exposed to the heat of the sun, and more plant food was thereby made available.

"(2) There was a higher percentage of silica in the pot-grown oats than in the field-grown grain. According to some experiments that have been conducted to ascertain the function of silica, it does not appear to be essential for growth and proper development. Large quantities, however, are used by some plants.

"(3) Phosphoric acid, one of the most important constituents of plants, is found in larger quantities in the field samples. Calcium and magnesium may also be noted in the same connection. The subsoil may have influenced this increase.

"(4) The pot-grown plants contain the largest proportion of potash. The percentage of potash is much higher in the straw than in the grain, while with phosphoric acid the opposite is the case."

Physical analysis of soils, J. B. REYNOLDS (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31, (1905), pp. 27–29.*)—The general physical properties of soils are briefly discussed in this article and the principal results of physical analysis of 42 samples of soil from the Abitibi district of Canada are summarized.

About 5 per cent of the soils analyzed seemed to be composed entirely of clay with little or no admixture of coarse particles, 39 per cent contained from 15 to 25 per cent of coarse or fine quartz particles, and 19 per cent from 25 to 40 per cent of sand and silt. Fifteen per cent of the samples were classed as

loam, 7 per cent as sandy loam, 5 per cent as light sandy loam, and the remainder were peat soils.

A preliminary examination of about 40 samples of soil from the Temiskaming district indicate that these soils are quite similar in physical structure and appearance to the Abitibi soils.

Experiments on peat soil, W. H. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 35–37*).—Studies of the capillary rise of water in a peat soil which in its natural state baked and cracked in dry weather and absorbed water badly are reported.

The studies were made in tubes with the loose and packed soil and with mixtures of the soil with sand, loam, marl, and lime. "Twenty-five per cent loam, 10 per cent marl, and 50 per cent sand increased the capillary rate by about 25 per cent, as compared with the rate in pure peat, so that soil treated in any of these ways is capable of supplying water to the plants much more rapidly than in the untreated state. Ten per cent lime, on the other hand, decreased the capillary rate by about 50 per cent as compared with pure peat."

The tubes in which the water rose highest did not contain as much water per cubic centimeter of soil as those in which the water rose more slowly. This was especially true of the soil mixed with 10 per cent lime.

Experiments made with oats grown on the soil in crocks showed that the strongest and most uniform growth, least affected by "damping off," was obtained in the mixture containing 25 per cent of loam.

The results in general show that "the peat can be much improved by adding either loam or sand, but seriously injured by 10 per cent of lime. . . . Twenty-five per cent loam and 20 per cent sand seem to be the best treatments tested."

Experiments on aeration, W. H. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 37–40, figs. 3*).—In these experiments wheat, barley, oats, and peas were grown on loam soil in 4-gal. jars, fitted with tubes at the bottom, which permitted air to be drawn through the soil. "Once each day during the growing season air was drawn through half the crocks of each kind of grain, enough to completely change the air in the crocks. Observations were taken on the germination, the growth of the plants, the yield, the rainfall, and the water added."

The results with the cereals were vitiated by depredations of sparrows, but "point to the importance in the case of legumes (peas) of having the soil thoroughly loosened up so as to permit thorough aeration to begin with, and the free entrance of air afterwards."

Experiments on evaporation and transpiration, W. H. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 40–42*).—Studies of the amount of water required during the season by wheat, barley, oats, and peas growing in 4.-gal. crocks are reported.

From the data given it appears "that the wheat up to August 3, when it was about ripe, had used 2.15 times as much water as the rain that had fallen. The barley to July 20, 2.25 times as much water as had fallen, and the oats during the same period 2.57 times the amount of rain. The peas up to August 15 had used 2.19 times the rain during that period. Hence, in case of these four grains much more water for the sustenance of the crop must come from the store held in the earth from the winter and spring rains than from the summer rains." The wheat required during the season 22.6 in. of water; the barley, 18.52 in.; oats, 21.15 in., and peas, 27.38 in.

The constitution of arable soil.—The soil of Ségala (Druelle) and the rocks from which it was derived, A. DEQAGE and H. LAGATU (*Ann. École Nat. Agr. Montpellier, n. ser., 5 (1905), No. 2, pp. 93–110*).—Detailed mineralogical examinations according to the authors' method, which has already been noted

(E. S. R., 16, p. 756), are reported. These show that the minerals in the soil are identical with those of the original rock from which it was derived, the only difference being that the crystals are entire in case of the rock and broken in case of the soil.

Soil builders at work, S. W. FLETCHER (*Country Life Amer., 9 (1906), No. 3, pp. 325–327, figs. 18*).—A popular discussion of the weathering of rocks; plants and animals as soil builders; and the action of ice, wind, and micro-organisms. Soil exhaustion as well as formation is considered.

Feldspar and mica as sources of potash, D. N. PRIANISHNIKOV (*Landw. Vers. Stat., 63 (1905), No. 1–2, pp. 151–156*).—Sand cultures with tobacco, buckwheat, flax, peas, sunflowers, and barley, in which these substances were used in fine-ground condition (less than 0.25 mm. in diameter) in connection with sodium nitrate, ammonium nitrate, ammonium sulphate, and calcium nitrate, are reported.

The results show that the orthoclase, even in large amounts, had very little effect on the growth of plants, either alone or in association with the other materials. Mica and apophyllite gave somewhat better results than the orthoclase. The associated salts therefore apparently did not exert the solvent effect which had been previously noted in the case of phosphates (E. S. R., 17, p. 538).

Investigations on the insoluble potassium compounds contained in humic substances, M. BERTHELOT (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 26, pp. 1182–1187; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 520, II, p. 117*).—In continuation of previous investigations[a] the author studied the double decomposition resulting from the action of the soluble alkaline salts of weak acids, such as the acetates of potassium and calcium, on wood charcoal exhausted of soluble compounds partly by treatment with pure water and partly by extraction with dilute hydrochloric acid.

The results indicate the presence in wood charcoal of compounds which in general behave toward the salts of potassium and calcium named like the humic acid artificially prepared from sugar. These compounds, however, are of two classes of unequal stability, one immediately destroyed by dilute hydrochloric acid, the other being more resistant to this reagent. The compounds are analogous in their properties and affinities to different artificial and natural silicates.

On the causes of unproductivity in a Rhode Island soil, H. J. WHEELER and J. F. BREAZEALE (*Rhode Island Sta. Rpt. 1905, pp. 286–323*).—This is an account of cooperative investigations between the Rhode Island Station and the Bureau of Soils of this Department, "to study the soluble toxic substances in a highly unproductive soil and also in soils in good tilth and of high productiveness."

The influence of the treatment of the extracts of such soils with nonnutritive solid materials and with certain soluble chemical substances (ferric hydrate, carbon black, calcium carbonate and sulphate, sodium chlorid, potassium sulphate, disodium phosphate, sodium nitrate, and pyrogallol) was studied by means of water cultures with wheat, both in the normal and treated extract. The conclusions reached are that the unproductiveness of the infertile Miami silt loam from the station farm is in some measure transmitted to the aqueous extract of the soil.

The beneficial effect of treatment of the extract with finely divided carbon black and ferric hydrate is taken "to indicate that the extract contained injurious bodies which were removed from or altered in the soil extract so as to become noninjurious, or partially so, by the action of the solids above named. Some evidence in the same direction is derived from the fact that treatment of

[a] Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 21, p. 793.

the extract with pyrogallol produced a gain in transpiration in all cases and in green weight in three of the five instances. This phenol can not be considered as a nutrient material, so that the conclusion is suggested that certain toxic substances present in the extract are acted on chemically by the pyrogallol and brought into a less injurious form. It is suggested that the beneficial action of calcium carbonate and calcium sulphate in these experiments may be in part of a similar nature.

"The soil extracts were unquestionably improved for the growth of wheat plants by the addition of considerable amounts of sodium nitrate, potassium sulphate, acid sodium phosphate, and in certain cases by sodium chlorid. . . . The question as to just how the salts acted in all particulars must be left an open one for the present.

"A comparison of the effects produced by the various treatments of the extract of the infertile soil with those produced by the same treatments upon extracts of two soils of the same farm which were in good condition for the growth of crops shows that none of the treatments produced nearly as good effects upon the extract of the good soil as upon that of the poor soil; yet treatment with carbon black and ferric hydrate in a few cases seemed to produce a small beneficial effect upon the extracts of the good soils, and these bodies were probably effective through the removal of injurious substances from the extract. Therefore it may be supposed that the toxic bodies which apparently exist in relatively large amounts in the extracts of the infertile soil may be present also to a slight extent in that of the good ones. . . . To attempt to claim from the data obtained that because these manurial substances are beneficial to soil extracts in other ways than through their nutritive effects, where such a possibility of action exists, and that hence they do not play the rôle of plant nutrients in the soil when added, is not intended, nor is it to be inferred. Neither is it questioned but that the so-called chemical manures do in most instances, where they are applied to the 'worn out' type of soils, exert a direct effect as nutrients upon the plants."

Soil inoculation with artificial cultures, M. Ferguson (*Virginia Sta. Bul. 159, pp. 81–96, figs. 3*).—This bulletin briefly reviews the history of investigation on this subject, including that of the Virginia Station begun in 1903, describes the author's methods of preparing and distributing the cultures (liquid cultures in sealed glass tubes with a time limit of life), and gives results of 344 tests of the material in different parts of the State. The conditions under which inoculation is likely to succeed or fail are stated.

Of the 344 persons who tried the cultures sent out by the station, 61 reported crop failures due to bad seed, bad season, or weeds and grass. Of the 283 remaining, 234, or 82 per cent, reported that the material was without doubt a success and that the crop was benefited by it. The reports of 27 showed that the soil already contained the proper bacteria and that the crop was not materially benefited by inoculation, and 22, or 8 per cent, did not observe any effect of the inoculation either by formation of nodules or increase in the crop.

The general conclusion is reached that inoculation can be successfully and profitably done when care is taken to observe proper methods, but a conservative course is recommended since "no amount of inoculation or anything else will make up for an imperfectly prepared seed bed, poor soil, bad season, and poor cultivation." It is not believed that the results obtained justify the paying of the large prices which have been asked for commercial cultures, and the station will continue to supply farmers of the State with cultures at a cost of 25 cts. per acre, provided the farmers will give the material a fair trial and report results.

Loss of nitrogen in putrefying peptone solutions. Bacteriological soil investigation, P. EHRENBERG (*Centbl. Bakt.* [*etc.*] *2. Abt., 15* (*1905*), *No. 4–6, pp. 154–164; abs. in Jour. Chem. Soc.* [*London*], *88* (*1905*), *No. 517, II, p. 750*).—The author calls attention to the fact that in determining the power of soils to produce putrefaction in peptone solutions it is necessary to make determinations with the whole contents of the flasks, thus avoiding filtration and the use of aliquot portions of the solution. The putrefying power of similar soils varies appreciably under different treatments. The loss of nitrogen occurring in putrefying peptone solutions inoculated with soil and then filtered is ascribed to absorption rather than biological fixation in the soil.

The absorptive power of soils for bone and mineral superphosphates, C. MONTANARI (*Chem. Ztg.*, *29* (*1905*), *No. 75, pp. 988, 989; abs. in Jour. Chem. Soc.* [*London*], *88* (*1905*), *No. 517, II, p. 759*).—The author briefly reports experiments carried out on kilogram lots of soils of different kinds treated in funnels with solutions of the different superphosphates, which indicate that the popular belief as to the greater activity of bone superphosphate is not supported by the facts. Apparently, however, the phosphoric acid of the mineral superphosphate was not quite so rapidly absorbed by the soils, although it is the author's opinion that the portion absorbed was more rapidly taken up by the plant roots.

On the effect of liming upon certain constituents of a soil, B. L. HARTWELL and J. W. KELLOGG (*Rhode Island Sta. Rpt. 1905, pp. 242–252*).—"Since 1893 two of the permanent experimental plats upon the station plain have received equal amounts of nitrogen annually in sulphate of ammonia, and two others in nitrate of soda. About 3.7 tons of air-slaked lime have been applied in all to one of the plats receiving sulphate of ammonia and to one of those receiving nitrate of soda. Equal amounts of muriate of potash and dissolved boneblack have been added annually to each plat."

Chemical studies of the influence of this treatment on the humus content and the composition (ash constituents) of the humus of the soil show that "the amount of humus is now less in the limed than in the unlimed plats. The amount of free humus is likewise less in the limed plats. A smaller part of the humus is present as free humus in the limed plats. The loss by igniting the oven-dry soil was somewhat less from the samples of the limed plats than from the unlimed ones.

"The total nitrogen in the limed plat to which nitrate of soda is applied is less than the amount common to the other three plats.

"In the case of the unlimed plats the one to which sulphate of ammonia has been added would require much more lime to neutralize it, according to the lime-water test, than the one which has received nitrate of soda. Upon the same basis, no further application of lime would be required for the limed plat to which nitrate of soda has been added, although the limed plat receiving sulphate of ammonia is still somewhat acid.

"Most of the ash left upon destroying the separated humus and free humus by ignition is composed of iron and aluminum oxids, phosphoric acid, and silica.

"In the case of the ash remaining from the free humus, that from the limed soils contained larger percentages of phosphoric acid and smaller percentages of silica than that from the unlimed soils.

"Surprisingly large amounts of iron were found in the ash left from the ignition of the humus and free humus. The iron in the ammoniacal solutions of humus could not be thrown out by certain of the ordinary precipitants.

"An artificial product made by precipitating the humus from an ammoniacal extract of leaf mold, by means of ferrous chlorid, contained in its oven-dry condition 11 per cent of ash, of which 83 per cent was ferric oxid, the remainder being phosphoric acid and silica."

Directions for liming (*Rev. Gén. Agron.*, *14* (*1905*), *No. 12*, *pp. 499–501*).—The rules formulated by the German Agricultural Society for this purpose are given.

Cultural management as applied to sewage irrigation at Paris, P. VINCEY (*Mém. Soc. Nat. Agr. France*, *141* (*1905*), *pp. 415–500*, *pl. 1*, *figs. 6*).—The theory of this method of sewage disposal is explained, the history of its use in disposing of the sewage of Paris is reviewed, and its efficiency and present status is discussed.

It is pointed out that the Paris system of sewage disposal has not yet been perfected so that it secures both perfect purification of the sewage and its complete utilization. While much has been done to introduce crop rotations, which secure a more complete and uniform utilization of the sewage throughout the year, the supply of sewage has grown so large that it is impossible to take care of it in winter, and even in summer it is often difficult to secure that intermittance of application which is essential to thorough purification. This is true in spite of the fact that the municipality has rapidly increased the area of its sewage farms.

The difficulties are increased in those cases in which the city does not own the land, but simply supplies the sewage to farmers and gardeners, as they are not willing to irrigate during the night except to a very limited extent in dry seasons. The present system is inadequate to dispose of the sewage of Paris, and so make it possible to suppress pollution of the Seine. It is claimed to be possible to so extend the present area and application as to dispose of 775,000 cubic meters of sewage per day, which will be amply sufficient.

Local fertilizer experiments in Malmöhus County, Sweden, 1904, G. NORDIN and M. WEIBULL (*Malmö. Läns K. Hushäll, Sällsk. Kvrtlsskr.*, *1905*, *No. 1*, *pp. 207–271*).—A brief account of the cooperative fertilizer trials conducted on a number of different farms under the auspices of the Malmöhus County Agricultural Society is given, and the following subjects are discussed at more length: The general effects of fertilizers as shown by experiments during recent years, analyses of lime and soil analyses in general, the after-effect of artificial fertilizers, experiments with calcium carbid, experiments with lime as a manure preservative, the influence of different fertilizers on the quality of root crops and experiments with oat sickness of soils.—F. W. WOLL.

Experiments with mineral fertilizers on the Krotkov estate, A. I. STEBUT (*Vyestnik Russ. Selsk. Khoz.*, *1904*, *Nos. 50*, *51*; *abs. in Zhur. Opuitn. Agron.* (*Russ. Jour. Expt. Landw.*), *6* (*1905*), *No. 2*, *pp. 245–247*).—The relative efficiency of drill and broadcast application of fertilizers is discussed on the basis of fertilizer experiments carried on at the Krotkov estate.

It is claimed that in drill application the fertilizers are placed where they are exhausted in the early stages of growth of the plant, which is thus forced into vigorous development, causing it to make increased demands upon soil fertility during later periods of growth. Drill fertilizing, therefore, not only does not increase the supply of plant food in the soil or provide fully for the requirements of the plant, but results in actual soil exhaustion. For drill fertilizing to yield best results the whole soil should be well supplied with plant food, the fertilizers applied in the drill acting mainly as a stimulus to the plant.

In the early stages of plant growth fertilizers which have been applied broadcast act in much the same manner as fertilizers applied in the drill, but they continue to furnish plant food through a longer period, depending upon the character of the root growth of the plant. If the plant has a limited root system or the season is dry, so that plant food does not circulate freely in the

soil solutions, a considerable amount of the fertilizing material applied broadcast may not be utilized by the plant.—F. FIREMAN.

Report on commercial fertilizers, 1905, E. H. JENKINS and A. L. WINTON (*Connecticut State Sta. Rpt. 1905, pt. 1, pp. 9–106*).—This includes a statement of the duties of manufacturers and dealers and of the experiment station in connection with the inspection under the State fertilizer law, a list of firms licensed to deal in fertilizers in the State during 1905, notes on the methods followed in sampling and collecting fertilizers, a classification of the fertilizers analyzed, descriptions (with analyses) of fertilizing material furnishing nitrogen, phosphoric acid, and potash in fertilizers, and explanations regarding the valuation of fertilizers.

Tabulated analyses and valuations are given of 600 samples of fertilizing materials, including nitrate of soda, dried blood, cotton-seed meal, castor pomace, flaxseed meal, dissolved rock phosphate, charred bone, carbonate of potash, high-grade sulphate of potash, double sulphate of potash and magnesia, muriate of potash, kainit, saltpeter waste, bone manures, slaughterhouse tankage, dry ground fish, superphosphates with potash salts, nitrogenous superphosphates, special manures, home-mixed fertilizers, vegetable potash, cotton-hull ashes, wood ashes, limekiln ashes, garbage ashes, lime, South American guano, sweepings from a fertilizer factory, dust from wheat, pulverized sheep manure, rotted cotton-seed compost, dust from tobacco, and woolen carpet waste.

The cash retail cost per pound in Connecticut of nitrogen in raw materials during 1905 as shown in this report was, in nitrate of soda, highest 17.5, lowest 16.4, average 16.9 cts.; dried blood, average 21.9 cts.; cotton-seed meal, highest 20.6, lowest 14.2, average 16.4 cts.; castor pomace, highest 24.5, lowest 20.4, average 22.4 cts.; and flaxseed meal, average 21.9 cts.

The price of available phosphoric acid in form of dissolved rock phosphate was, highest 4.8, lowest 4.3, average 4.5 cts. per pound.

The price per pound of potash in raw materials was, in high-grade carbonate, highest 7.3, lowest 6.7, average 7.1 cts.; carbonate as "vegetable potash," highest 8.1, lowest 7.9, average 8 cts.; high-grade sulphate, highest 5.3, lowest 4.8, average 5 cts.; double sulphate, highest 5.9, lowest 4.9, average 5.3 cts.; muriate of potash, highest 4.5, lowest 4, average 4.25 cts.; saltpeter waste, average, 0.7 ct.; and kainit, average 4.7 cts.

The price of lime per 100 lbs. was, in wood ashes, average 34 cts.; limekiln ashes, highest 15, lowest 4.3; and ground slaked lime, average 85 cts.

Commercial fertilizers, P. EVANS (*Missouri Fruit Sta. Bul. 13, pp. 23, fig. 1*).—In this bulletin an attempt is made to give "such information pertaining to the use of fertilizers as may be of use to the general inquirer. The information offered, however, does not come from the results of actual experiments conducted at this station, but rather is a general summary of the subject."

Analyses and valuations of commercial fertilizers, J. P. STREET, W. P. ALLEN, and V. J. CARBERRY (*New Jersey Stas. Bul. 188, pp. 46*).—This is a second report on fertilizer inspection during 1905, the first being given in Bulletin 187 of the station (E. S. R., 17, p. 450).

The trade values of fertilizing ingredients for 1905 are discussed and the composition of standard materials supplying them, station valuations are compared with actual selling prices, suggestions made regarding the purchase of fertilizers, and results reported of examinations of 104 samples of standard unmixed materials, 11 home mixtures, 20 special mixtures, 380 complete fertilizers, and 29 miscellaneous materials. "With a few exceptions the analyses indicate that the materials were of good quality, although the usual wide variations are shown in the case of dried fish and tankage."

Report of analyses of samples of fertilizers collected by the [New York] commissioner of agriculture during 1905 (*New York State Sta. Bul. 272, pp. 403–470*).—This bulletin gives in tabular form without discussion of any kind the analyses of samples of fertilizers collected by the commissioner of agriculture during 1905 and transmitted by him for analysis to the director of the New York State Station.

Fertilizer analyses, fall season, 1904, to spring season, 1905, B. W. KILGORE (*Bul. N. C. Bd. Agr., 26 (1905), No. 7, pp. 77*).—The names and guaranteed composition of fertilizers registered for 1905, and analyses and valuations of 679 samples of commercial fertilizers and 108 samples of cotton-seed meal, examined during the fall of 1904 and spring of 1905, with explanations regarding terms used in fertilizer analyses, freight rates, valuation, etc.

Commercial fertilizers, W. W. MILLER and N. W. LORD (*Ann. Rpt. Ohio Bd. Agr., 59 (1904), pp. 250–317*).—This is a report of analyses of commercial fertilizers made by the State chemist and of certificates filed by manufacturers or general agents during the year 1904, with the text of the State fertilizer law.

Miscellaneous analyses, B. L. HARTWELL, J. W. KELLOGG, and M. STEEL (*Rhode Island Sta. Rpt. 1905, pp. 223–226*).—Analyses (in some cases partial) are reported of "hydrated" lime, muck (air dried), soot from soft coal, street sweepings, ashes of hospital refuse, wood ashes, coal ashes, sawdust ashes from machine shop, black bone, guano, acid phosphate (dissolved phosphate rock), floats (undissolved phosphate rock), finely ground bone, dissolved bone, star fish (air dried), dried blood, nitrate of soda, sulphate of ammonia, muriate of potash, high-grade muriate of potash, high-grade sulphate of potash, potassium carbonate, sodium chlorid (common salt), sodium carbonate, Rhode Island corn bran, and cotton-seed meal.

Night soil, A. GRAU (*Jour. Agr. Prat., n. ser., 10 (1905), No. 50, pp. 754, 755*).—This article discusses briefly the preparation, variation in composition, and use of this material.

The production of manure, green manuring, and the purchase of commercial fertilizers, F. AEREBOE (*Fühling's Landw. Ztg., 54 (1905), No. 19, pp. 633–639*).—A general discussion of this subject.

Significance of ashes as fertilizer, D. N. PRIANISHNIKOV (*Vyestnik Russ. Selsk. Khoz., 1904, No. 11; abs. in Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 1, p. 50*).—Ashes are usually valued mainly as a potash fertilizer, but, according to the author's experiments on sandy soils, it has been demonstrated that ashes not only appear as a rich potash fertilizer, but their phosphoric acid, even that insoluble in water, possesses a high degree of assimilability (higher than the phosphoric acid of bones and but slightly inferior to superphosphate). The application of too large amounts of ashes, however, leads to the formation of a crust and an alkaline reaction in the soil which is not desirable.—P. FIREMAN.

Transformations of sodium nitrate in the soil of sugar-beet plantations, J. STOKLASA (*Ztschr. Zuckerindus. Böhmen, 30 (1905), pp. 1–8; abs. in Jour. Soc. Chem. Indus., 24 (1905), No. 21, pp. 1118, 1119*).—This article attempts to explain the fact that when sodium nitrate is applied to sugar beets very little of the nitrogen is washed out of the soil in normal seasons, but remains available in the humus of the surface soil. This is ascribed partly to assimilation by the beets and partly to the fixation of the nitrogen in organic forms as a result of biological processes, this organic nitrogen becoming available as it is required by the plants.

Chilean nitrate production and trade, R. E. MANSFIELD (*Mo. Consular Rpts. [U. S.], 1905, No. 297, pp. 129, 130*).—The statistics of this industry for 1904

are briefly summarized, showing that the production of nitrate in Chile in that year was 1,694,665 tons, which is 80,230 tons in excess of the production in 1903. The total exports were 1,630,488 tons, or 45,745 tons more than in 1903. The statistics show an increase in consumption of nitrate in the United States, but a slight decrease in Europe (France, Belgium, and Italy).

Calcium cyanamid and its use in agriculture, A. D'ERCOLE (*La calciocianamide ed il suo migliore impiego in agricoltura. Rome, 1906, pp. 120, pl. 1, figs. 15*).—This elaborate report, published by the Italian Society for the Manufacture of Agricultural Products, etc., after briefly referring to the principal nitrogen compounds used as fertilizers, discusses the utilization of atmospheric nitrogen, especially in the form of calcium cyanamid, reviewing experiments by various investigators with this substance, and reports in detail a large number of experiments with the substance on all classes of farm crops. The wide applicability of this material as a fertilizer is indicated by the results of these experiments.

Thomas-ammonium-phosphate, a new manure; its composition and results of manurial experiments in 1904, MÜLLER (*Illus. Landw. Ztg., 25 (1905), No. 32, pp. 303, 304; abs. in Jour. Chem. Soc. [London], 88 (1905), No. 516, II, p. 650*).—This material is a mixture of Thomas slag or superphosphate and ammonium salts. In experiments with wheat, oats, rye, potatoes, and mangel-wurzels a mixture of slag and ammonium salts gave very satisfactory results. The fertilizer should be applied as a top dressing. There is little loss of nitrogen from the mixture if it is used soon after its preparation.

Ground rock for fertilizing purposes, A. S. CUSHMAN (*Science, n. ser., 22 (1905), No. 573, pp. 838, 839*).—Attention is called to a series of experiments with tobacco seedlings which it is claimed showed "that fine-ground orthoclase was very nearly, if not quite, as efficient as a source of potash plant food as the more soluble potash salts which are in ordinary use," and it is suggested that with improvements in methods and machines for grinding rock and transportation facilities "not only some of our feldspar deposits but even our richer potash-bearing feldspathic rock, like some of the granites," may be profitably employed as a source of potash.

Potassium salts, W. M. COURTIS (*Extr. from Mineral Resources of the United States, 1904. U. S. Geol. Survey, 1905, pp. 16*).—This paper gives statistics of the potash industry of Germany and discusses the possibility of finding potash and attempts to locate deposits in the United States.

Indications of possible potash deposits found in saline springs, oil wells, and bore holes, and in desert deposits are described, with determinations of potash in salts from various saline springs and desert deposits in California and Nevada. Seven localities in the United States which seem to offer favorable conditions for the discovery of potash deposits by boring are named as follows: Cody, Wyo.; Magnesian Lake, near Laramie, Wyo.; Byron Springs, Contra Costa Co., Cal.; Death Valley, Cal.; Sierra de las Cucapas basin, Lower California, extending into San Diego Co., Cal.; Boundbrook, N. J.; and Mount Tom, Mass. The report contains a bibliography of potassium salts.

AGRICULTURAL BOTANY.

Relation of transpiration to growth in wheat, B. E. LIVINGSTON (*Bot. Gaz., 40 (1905), No. 3, pp. 178–195, figs. 21*).—Investigations are reported on the relation between transpiration and the growth of wheat, cultures being grown in soil in wire baskets covered with paraffin, and water cultures grown in black bottles were used for comparison.

From the experiments the author concludes that total transpiration of wheat plants grown in various media is as good a criterion for comparing the relative growth in these media as is the weight of the plants. The amount of transpiration is practically a simple function of the leaf surface, and this varies with the leaf weight, which in turn varies with the weight of the entire tops. Thus it is believed that total transpiration is a measure for the growth of the plant.

It is held that the nature of the soil or solution in which the roots are grown has little or no influence on those structural and physiological properties of the leaves which control the amount of water lost per unit of leaf surface. In making use of this criterion of transpiration for the comparison of different nutrient media, the author says that it must be borne in mind that there will occur variations which appear to be unexplained. On this account the larger the number of plants used the nearer the results will approach the average.

It is shown also that temperature, atmospheric conditions, etc., influence total transpiration, and these factors must be considered in investigations of this kind.

The methods for comparison of plant growth provisionally established for wheat are said to hold good for grasses generally.

The development of root hairs, LAETITIA M. SNOW (*Bot. Gaz., 40 (1905), No. 1, pp. 12–48, pl. 1, figs. 6*).—The author reports investigations on the causes for the production of root hairs, preliminary experiments being made with a large number of plants and detailed investigations carried on with seedlings of wheat, corn, pea, and squash.

The effect of various factors in determining the development is shown, the author stating that light and darkness appear to have an indirect effect through their influence on growth. High temperature with sufficient moisture decreased the production of root hairs with an increased elongation of the internal cells. The slower the growth of the roots the better the development of the root hairs. Retardation of growth by glass tubes, wounding, or resistance favored root-hair production.

The roots of corn seedlings in water first assumed a curled condition, producing abundant root hairs, but later they grew straight and smooth, either on account of accommodation to the oxygen supply or because that gas was supplied through the aerial parts. A saturated atmosphere with high temperature tended to suppress the development of hairs, and a saturated soil showed a similar effect on corn and wheat seedlings. Curves and swellings on roots had a favorable effect upon the development of root hairs, probably on account of the retardation of the growth of the root.

The examples of retardation favoring root-hair development showed that it was not the rate of growth but the differential elongation of the inner and outer cells that was the important factor. Root-hair production seems to depend on the ratio between the capacity of the epidermal cells to elongate and their ability to do so, and the activity of the epidermis may be in inverse proportion to the activity of the central cylinder, lateral roots appearing when the root hairs are suppressed.

A bibliography of literature relating to this subject is appended.

Agricultural microbiology, E. KAYSER (*Microbiologie Agricole. Paris: J. B. Baillière & Sons, 1905, pp. XXI+440, figs. 100*).—In the introductory part of this book the author describes in a general way micro-organisms and the effects of physical and chemical agents upon their development, after which he takes up the rôle which they play in soil fertilization, describing their distribution through the soil, their action on manures, nitrification and denitrification, fixation of atmospheric nitrogen, etc.

In other parts of the work bacteria as applied to the transformation of vegetable and animal products are discussed under the headings of fermentation, vinegar manufacture, starch manufacture, baking, fruit and vegetable preservation, silage, flax retting, tobacco fermentation, and the bacteria of the dairy, tannery, etc.

On proteolytic enzyms, II, A. L. DEAN (*Bot. Gaz.*, *40* (*1905*), *No. 2*, *pp. 121–134*).—A study was made of the proteolytic enzyms of beans to determine the distribution of erepsin.

The results of the investigations show that the proteids of the seeds of beans undergo proteolysis during germination, as a preliminary to the transportation of the nitrogen and its utilization in the formation of new organs. The author says there are 3 ways in which this process may be carried out—by the action of a tryptic enzym, by the combined action of the protoplasm and of an enzym which by itself is incapable of carrying out the whole process, or by the action of the protoplasm alone.

The results of his studies of the resting and germinating beans show that there is no enzym present which is able to digest the proteids of the seed. There is present, however, an enzym of the ereptase group which is capable of digesting the proteoses resulting from the partial hydrolysis of the seed proteids. It is believed possible, therefore, that the protoplasm of the cells starts the process of proteid decomposition and carries it to some stage at which the ereptase takes up the work and completes the process.

On the structure and biology of the yeast plant, F. MUTCHLER (*Jour. Med. Research*, *14* (*1905*), *No. 1*, *pp. 13–50*, *pl. 1*).—The author describes investigations on the structure and biology of the yeast plant (*Saccharomyces cerevisiæ*), in which some important discoveries relative to the yeast plant were determined.

The author reports the presence of a relatively large nucleus, a definitely marked nuclear membrane, and characteristically differentiated granules and a reticulated network within the nucleus, which stains in every way as do the nucleoli of the cells, and the young cells are said to have the same organization as the more mature ones.

In studying the biology of the yeast plant the author experimented with pure cultures in various culture media, in which the effect of various agents upon growth was determined, and he concludes that from his investigations *S. cerevisiæ* is not a variable species, and any variation in form observed is due to the inherent nature of the cell rather than to external conditions. Variation in the size and rate of growth of cells may be produced by changes in the conditions under which they grow, and anesthetics do not permanently destroy growth or reproduction of this species.

Synthetic culture media and the biochemistry of bacterial pigments, M. X. SULLIVAN (*Jour. Med. Research*, *14* (*1905*), *No. 1*, *pp. 109–160*).—The author reports upon a series of investigations in which he undertook to grow bacteria in nutrient media of very simple composition and to also determine the conditions under which bacteria develop their pigments.

The experiments show that bacteria can in a great measure be grown on very simple media, and that from these simple combinations the micro-organisms can elaborate not only the protoplasm they require but also materials which pass through a porcelain filter and gives reaction for albumins. Not only can bacteria synthesize complex bodies from simpler compounds, but they are able to carry out their activity, producing pigment and in some cases forming ferments or enzyms. It was found possible to develop in an organism the power to grow on simple salts, either by accommodating the medium to the organism or adapting it to the medium.

Summarizing his investigations, the author concludes that the line previously drawn between chlorophyll-containing plants and those containing no chlorophyll, based upon their ability to build up protoplasm and albuminous products from simple solutions, can not be so sharply held as formerly.

The production of the different pigments is described, and the influence of different media on pigment production is shown. Pyocyanin is formed where there is present a suitable combination of carbon, hydrogen, oxygen, and nitrogen, together with some salt or salts to aid in the synthesis. For the formation of fluorescent pigments both sulphur and phosphorus are essential. The production of fluorescent pigments is favored by a high phosphate content and a slightly alkaline reaction. The red pigments of a number of species require the presence of magnesium sulphate and a phosphate, preferably potassium phosphate. The rose-red pigments investigated are produced only in the presence of lactic acid, while the yellow pigments of a number of species and a few red pigments are formed very slowly in nonalbuminous media.

The salts which favor the production of pigments are necessary, not to render the solution isosmotic, but for the direct nutrition of the bacteria or to fix the acids produced, which otherwise would have a toxic effect on the bacteria. The formation of pigment is dépendent upon the reaction of the media, suitable ranges of temperature, and the free access of oxygen. Abnormal temperatures, acid or alkaline media, and a lack of oxygen lead to a colorless growth. Besides the pigments and albumin-like bodies the chromogenic bacteria form acids and ammonia, which apparently arise from the breaking up of asparagin or sugar and are independent of pigment formation. The production of pigment, it is held, is not an essential, vital act.

The author concludes with an extensive chronological list of publications relating to the subject.

The mistletoes of caoutchouc, O. WARBURG (*Tropenpflanzer, 9 (1905), No. 11, pp. 633–647, figs. 5*).—Descriptions are given of species of Strutanthus, Phthirusa, and Phoradendron which attack caoutchouc and also occur on a number of other plants of economic importance in the Tropics.

New pocket atlas on edible and poisonous mushrooms, P. DUMÉE (*Nouvel atlas de poche des champignons comestibles et vénéneux. Paris: P. Klincksieck, 1905, pp. XV+145, pls. 64*).—Brief descriptions with colored illustrations of 66 species of mushrooms.

FIELD CROPS.

Report of the experimentalist, C. A. ZAVITZ (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 165–221, figs. 9*).—In a 4-year experiment with 12 varieties and classes of farm crops, common emmer stood first in average yield of grain with 2,621 lbs. per acre, Mandscheuri barley second with 2,616 lbs., and Joanette oats third with 2,497 lbs. It is estimated that barley has about 12 to 15 per cent of hull, emmer about 22 per cent, and oats approximately 30 per cent. The lowest yields of grain were secured from common grass peas and common spring vetch, the yields being 768 and 722 lbs. per acre, respectively. The adaptation of particular varieties of field crops to certain localities and soil conditions is pointed out.

The average results from 1 year's seed selection show that large seed surpassed small seed by 19.1 per cent for 5 grain crops, 40.3 per cent for rape, and 60.1 per cent for 5 kinds of field roots. The average results of several years show that plump seed of barley and wheat gave a yield of grain 20.2 per cent greater than shrunken seed. Experiments conducted for 6 years with sound and broken

seeds gave the following results: Barley 53.8 and 46 bu., winter wheat 46.9 and 9.3 bu., and peas 29.2 and 10.2 bu. per acre for the sound and broken seed, respectively.

Seed of Joanette black oats has been selected for 13 years in succession. In 1905 large plump seed produced 65.5, light seed 44.7, and hulled seed 69.4 bu. per acre, with the weights per measured bushel 35.5, 24.3, and 34.3 lbs., respectively. It required 1,149 grains of the crop from the large plump seed to weigh an ounce and 2,066 grains of the crop from the light seed for the same weight. Crops of oats, barley, and potatoes have been grown in the experimental department without change of seed for 16 years and for the 4 4-year periods the average results were as follows: Oats 74, 79, 83, and 100 bu.; barley 50, 54, 63, and 63 bu.; and potatoes 120, 216, 218, and 249 bu. per acre. These results show that the average yields for the last period surpassed the first period by 26 bu. per acre for oats, 13 for barley, and 129 for potatoes, and that therefore grain and potatoes can be grown for a number of years without change of seed with proper selection of seed and handling of crop.

Work in the improvement of the varieties of grain crops by plant selection showed that hand planting gave a much better opportunity for the plants to grow under uniform conditions than any other method. The crops were grown from seeds selected in 1903, and from seeds from selected plants in 1904, and planted 1 ft. apart each way. The average number of heads per plant the second year was as follows: Mandscheuri barley 13.5, Chevalier barley 31.7, Siberian oats 18.4, and Joanette oats 46.9. The results with improved strains of leading varieties of spring grain were compared, and in every case the yield of grain from seed obtained from selected plants was higher than that from seed from unselected plants.

In connection with this selection work it was ascertained that in 1905 the progeny of a single seed of different crops planted in 1903 amounted to 1,929 lbs. of Mandscheuri barley, 1,119 lbs. of Chevalier barley, 2,109 lbs. of hulless barley, 2,102 lbs. of Siberian oats, 3,439 lbs. of Joanette oats, and 241 lbs. of Wild Goose wheat. Of 250 varieties of oats under experiment, Joanette has produced the greatest yield of grain per acre, has been the greatest stooler, and has furnished grain exceedingly thin in the hull. It is, however, very short in the straw and it has, therefore, been crossed with Siberian, which has a straw of better quality and a white grain, but is not equal to the Joanette in the other characters. Some of the hybrids secured are long in the straw, possess good stooling qualities, and produce a white grain with a thin hull.

A test of different grain mixtures indicates that a mixture of oats and barley generally gives the highest grain production. Early Daubeney oats and Mandscheuri barley are recommended for this combination. Two varieties of winter wheat grown in a mixture gave practically the same results as the 2 varieties grown separately.

For 5 years oats, barley, spring wheat, and peas were sown on each of 6 dates in each year, the average first date being April 18 and the last May 23. For every day's delay in the seeding after the first week had passed in which the seeding was done there was an average decrease of 56 lbs. of oats, 53 of barley, 29 of spring wheat, and 23 of peas per acre. The results of a similar experiment with emmer and spelt show that spelt gave much the best yield from the first date of seeding, while emmer gave, on the average, better yields from late seeding. Emmer gave much better yields of grain than spelt.

Winter wheat sown during the first 10 days of September in each of 9 years yielded 5.2 bu. more than that sown from September 16 to 20. The average results of 6 tests in the time of cutting winter wheat were in favor of allowing

the crop to become very ripe. Sowing about 90 lbs. of winter wheat per acre on average soil is recommended. In 1905 the greatest yield of flaxseed per acre, less the seed used, was obtained from 2 pks. per acre. Oats and barley grown with red and alsike clover gave a slightly increased yield of grain, and when grown with timothy a slightly decreased yield per acre as compared with growing the crops by themselves.

During the past 17 years 279 different varieties of oats were tested, and of this number the greatest average yields per acre were produced by Joanette, Siberian, Waterloo, Oderbruck, Probstei, and Bavarian. From 1898 to 1903, 86 varieties of barley were compared. Four varieties of 6-rowed barley now under experiment for 16 years gave the following average yields per acre: Mandscheuri 69.8, Oderbruck 63, Common Six-rowed 61.1, and Mensury 58.7 bu. Of 2-rowed varieties grown for the past 5 years Two-rowed Canadian, Selected Canadian Thorpe, Jarman Selected Beardless, Duckbill, New Zealand Chevalier, and French Chevalier have ranked highest. In the average results for 5 years with hulless barley the following varieties ranked first with the yields given: Guy Mayle 51.8, Purple 48.5, Black Hulless 47.9, and Hungarian 46.8 bu. per acre. In 8 out of the past 13 years winter barley was successful, the average yield for the 8 years being 64.1 bu. per acre.

Fifteen varieties of winter wheat ranged in average yield for 5 years from 45.9 to 57.3 bu., and in the yield of straw from 3.2 to 4 tons per acre. The leading varieties mentioned in decreasing order of yield were Dawson Golden Chaff, Imperial Amber, Early Genesee Giant, Russian Amber, Early Red Clawson, and Egyptian Amber, all yielding over 50 bu. per acre. In general the white wheats yielded more grain per acre, produced a stronger straw, weighed a little less, and were slightly softer in the grain than the red varieties. The leading varieties of durum wheats grown for 5 years and their average yields were as follows: Wild Goose 40.2, Sorentina 36, Medeah 35.7, Bart Tremenia 33.8, Algiers 33.1, and Ontario 25.6 bu. per acre. In a 5-year average Wild Goose produced about 60 per cent more grain per acre than Polish wheat (*Triticum polonicum*).

The leading variety of spring rye, as determined by the average results for 8 years, was Dakota Mammoth, which gave an average of 37.9 bu. per acre. Mammoth White rye in the average of 6 years' tests produced 60.4 bu. per acre.

Various other field and forage crops were tested for different numbers of years, the leading varieties being as follows: *Buckwheat*—Silver Hull and Japanese; *field peas*—Early Britain; *field beans*—Pearce Improved Tree, White Wonder, Medium or Navy, Burlingame Medium, Schofield Pea, and Day Improved Leafless; *soy beans*—Early Yellow and Medium Green; *corn for grain*—King Philip, Genesee Valley, and Longfellow; *sorghum*—Early Japanese Broom Corn, Improved Evergreen Broom Corn, and California Golden Broom Corn; *millet*—Siberian, Hungarian Grass, German or Golden, California, and Early Harvest; *sunflowers*—Mammoth Russian White Beauty and Black Giant. In 1905 Manitoba and Common flax yielded 22.2 and 20.5 bu. of seed per acre, respectively, while Russian yielded only 16.2 and Holland 13.1 bu. per acre.

This season 104 varieties of potatoes were compared. The results for the past 3 years show that Robertson Champion, Stray Beauty, Early Pinkeye, Holborn Abundance, Skerries, Green Bay, and Seedling No. 230 had less than 5 per cent of rot in the average crop, while Montana Bluff had over 40 per cent and Beauty of Hebron, White Pinkeye, and Hanlan Beauty between 37 and 40 per cent. The best yields in 1905 were secured from Lightning Express and Davies Warrior, producing 427 and 420 bu. per acre, respectively. Factor, the lowest-yielding sort, produced 130 bu. The medium-ripening sorts were most

subject to rot and the latest-ripening varieties least so in 1904 as well as 1905.

In the average for 4 years the following varieties produced the greatest yields at 9 weeks after planting: Early Andes 174, Early Fortunate 170, Six Weeks 169, and Early Dominion 167 bu., and the lowest average yields at the end of the same length of time were produced by Burpee Extra Early, 113, and Stray Beauty, 124 bu. per acre. The results of 11 years of continuous seed potato selection show that in 1905 204 bu. was obtained from large whole potatoes, 183 bu. from medium-sized whole potatoes, 142 bu. from small whole potatoes, and 105 bu. per acre from very small whole potatoes. The percentage of small potatoes in the crops increased as the size of the seed decreased.

The use of 1 2-oz. potato set in the hill in the average for 6 years gave 211.9 bu., 2 1-oz. pieces 203.7 bu., and 4 ½-oz. sets in the hill 182.5 bu. per acre. The largest percentage of marketable tubers was secured from the 1 2-oz. set per hill planting. In 6 out of 7 years, planting potato sets 1 ft. apart in the row gave better yields than planting them in squares 33 in. apart each way. The average results for 7 years rather favor hilling than level cultivation. An application of 2 tons of poultry manure per acre gave better yields than the use of smaller or greater quantities, the yield of potatoes being increased by 56 bu. per acre.

In 1905 the following varieties of swedes ranked first in yield: Rennie Queen 22.8, Cropwell, 22.5, Good Luck and Sutton Queen 21.3, and Keepwell 21.1 tons per acre. Thinning the plants at one-half, 2, 5, and 8 in. in height resulted in the best yield from the thinning when the plants were very small. The yield of roots per acre from applications of cow manure and mixed fertilizer was about the same. The average yields with 4 varieties of fall turnips grown for 5 years were as follows: Red Top White Globe, 27.9, White Egg 23.1, Early American Purple Top 22.1, and Cow Horn 20.3 tons per acre.

Among 15 varieties of mangels grown for 5 years Yellow Leviathan stood first with an average yield of 33 tons of roots per acre, being followed by Steele-Briggs Giant Yellow Intermediate, Sutton Mammoth Long Red, and Mammoth Golden Giant. The average yield of tops per acre of the 15 varieties ranged from 2.1 to 6.4 tons per acre. In 3 out of 4 years seed soaked for 12 hours gave greater yields per acre than seed not soaked before sowing and that soaked for 24 and 36 hours.

Notes are also given on experiments with sugar beets and carrots. In experiments with varieties of silage corn it was observed that there was a variation from 15.2 to 24.1 tons of total crop per acre between the lowest and the highest-yielding strains of White Cap Yellow Dent, one of the best general purpose varieties for southern Ontario. Deep cultivation immediately after planting, followed by shallower cultivation as the season advanced, produced the largest yield per acre. In general, planting in hills 40 in. apart both ways with 4 plants in each hill, has given better results than planting 10 in. apart in the row. The results with several other forage crops, including sorghum, millet, rape, kale, cabbage, sunflowers, grass and grass mixtures, and a number of leguminous plants are reviewed.

Department of field experiments, P. O. VANATTER (*Virginia Sta. Rpt. 1905, pp. 30–33*).—The different lines of experimental work in progress are briefly described and some of the results obtained are given.

Fulcaster winter wheat proved one of the best-yielding varieties. Winter wheat, winter barley, and winter oats gave the best results when sown September 30 and winter rye when sown a month later. The yields of these winter crops were as follows: Fulcaster wheat 17 bu., Union barley 32 bu., Culbertson oats 56 bu., and Excelsior rye 26 bu. per acre. Of 25 varieties

of spring oats compared, Silver Mine and Texas Rust-proof led in yield with 39 and 35 bu., respectively, while the common oat generally grown in the State yielded only 11 bu.

The 6 leading varieties of corn tested were Boone County White, Virginia Golden Dent, Hickory King, Cocke Prolific, Blount Prolific, and Leaming. Boone County White ranked first in yield of grain per acre with 53.78 bu., being followed by Virginia Golden Dent with 52.84 bu. Leaming, which ranked last in yield, ranked first in earliness and was the only variety requiring a shorter period of growth than Boone County White. Blount Prolific gave the smallest percentage of barren stalks and Leaming the largest. A yield of 23 tons per acre was secured from St. Andrew ruta-baga.

Experiments at Ploty in 1904, P. Troubetzkoy (*Separate from Ghodichnuii Otchet Ploty, Selsk. Khoz. Opuitn. Stantzii, 10 (1905), pp. 31, dgm. 1*).—On account of an unfavorable season the yield of sanfoin did not exceed 2,580 kg. of hay, and the yield of beets varied from only 10,500 to 15,000 kg. per hectare.

Plowing 26.5 cm. deep decreased the yield of small grains by 14.3 per cent and of corn by 44.6 per cent as compared with plowing 8.8 cm. deep. The yields of sugar beets and potatoes, however, were better on deep than shallow plowing. Fall plowing for spring wheat gave an increase in yield of 450 kg. per hectare over spring plowing. It was found that even in a dry year barnyard manure was capable of increasing the yield of winter wheat by 41.4 per cent, sugar beets by 62 per cent, and spring wheat by 4 per cent. As the result of following perennial leguminous forage crops in the rotation the yield of winter wheat was apparently increased 33.3 per cent; that of sugar beets, 27 per cent; and of spring wheat, 6 per cent.

Reports from the director of agriculture on the government farms at Nairobi and Naivasha in the East Africa Protectorate for the year 1904, and on the prospects of settlers (*London: Parliament, 1905, pp. 49, pls. 12*).—Detailed descriptions are given of the equipment and work of the experimental zebra ranch and stock farm at Naivasha and the experiment farm at Nairobi. Brief notes on the field and garden crops grown at Nairobi are given, meteorological data recorded, and the prospects of settlers in the East Africa Protectorate are discussed.

Annual report of the Burdwan Experimental Farm for the year 1903–4, D. N. Mookerji (*Ann. Rpt. Burdwan Expt. Farm [India], 1903–4, pp. 10*).—General notes on the work of the farm, together with meteorological data and the results of experiments with various crops are presented.

In fertilizer experiments with paddy the best yields of grain and straw for 2 successive years were obtained where 240 lbs. of bone meal and 60 lbs. of nitrate of soda were applied per acre. The use of 8,000 lbs. of cow manure or 480 lbs. of bone meal gave nearly as good results. In a test with different fertilizers given in quantities supplying 50 lbs. of nitrogen per acre, the best yields were obtained where bone meal or bone meal and nitrate of soda were used. The best financial returns were secured from the use of nitrogen alone.

In an experiment testing the effect of green manuring for paddy the largest yields and the highest profits were secured where jute was plowed under. In cultivation tests with paddy spacing the clumps 12 in. apart in transplanting gave the best results. The comparative yields of 3 Bengal and 3 Bombay varieties of paddy are recorded.

In experiments with potatoes, castor cake used at the rate of 1,920 lbs. per acre gave apparently the largest yield, and in a green manuring experiment the largest yields were obtained where dhaincha was plowed under and cow manure and castor cake were applied singly. Whole tubers seemed to give

higher yields than cut sets, but the experiment did not show whether the lower yield in the case of cut sets was due to the cutting or to the smaller quantity of seed used.

The results of culture tests with sugar cane were in favor of the Poona system of irrigation beds about 10 ft. square and the Behar system of planting in double lines in trenches 3 ft. wide, separated by ridges of equal width.

Annual report of the Dumraon Experimental Farm for the year 1903-4, D. N. MOOKERJI (*Ann. Rpt. Dumraon Expt. Farm [India], 1903-4, pp. 9*).—A brief description of the farm, together with chemical analyses of the soil and meteorological data for the season are given. The best yields of grain and straw of paddy were secured where either 2,960 lbs. of cow manure or 1,456 lbs. of cow manure and 260 lbs. of castor cake were applied per acre. Among 6 varieties of paddy Sukhavel, a Bombay variety, and Badshabhog and Basmati, Bengal varieties, gave the best yields.

The highest yields of wheat for 2 successive years, as well as the best financial returns, were obtained on land fertilized with 6,984 lbs. of poudrette per acre. The Behar and Poona systems of planting sugar cane showed an advantage over the local system of planting. Planting whole sets of potatoes gave larger yields than the use of cut sets. The local variety of oats was more productive of grain and straw than Canadian Welcome.

Brief notes are also given on the culture of corn, mustard, rape, sweet potatoes, and forage crops.

Successful yields of small grains, G. W. CARVER (*Alabama Tuskegee Sta. Bul. 8, pp. 10, figs. 6*).—Cultural tests with wheat, rye, barley, and oats are reported, with estimates of cost of production and return. The results indicated that for the small grains in that section deep plowing, clean seed, and proper crop rotation are essential to their profitable culture, and that a crop of pea vines turned under is a very valuable fertilizer in this connection.

Lodged grain, R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 91, 92*).—In connection with a study of preventing the lodging of oats the composition of the soil on which standing and lodged grain was found was determined, and is reported in a table. The plats on which the grain lodged contained the least lime and the most nitrogen.

Nutrients taken up by plants in different stages of growth, H. WILFARTH, H. RÖMER, and G. WIMMER (*Landw. Vers. Stat., 63 (1905), No. 1-2, pp. 1-70*).—Pot and field experiments were conducted for several years to study the quantities of fertilizing materials taken up by different crops in various stages of growth. The work is described and the analytical data secured are reported in tables.

Barley, spring wheat, peas, and mustard were found to have taken up the maximum quantity of fertilizing materials at the time of blossoming, or at the beginning of fruit formation. With the exception of phosphoric acid, part of this quantity of food elements returned to the soil as the crops approached maturity and this movement seemed to be dependent upon the supply of available plant food. As determined for potash, relatively larger amounts returned to the soil when the supply was inadequate than when it was sufficient.

Potatoes continued to take up plant food until ready to be harvested and a return movement to the soil did not take place. When the food supply was normal the quantity of dry matter increased until the plants were ripe. Starch also increased up to maturity in all plants except mustard, in which fat is substituted for the starch grains.

Alfalfa, G. A. BILLINGS (*New Jersey Stas. Bul. 190, pp. 1-19, pls. 4*).—The value of alfalfa as a forage crop is discussed and the methods of culture, includ-

ing directions for soil inoculation are outlined. It is reported that 16 acres of the college farm are devoted to this crop. As a remedy for blight, which attacks alfalfa fields in spots, cutting as soon as it appears is recommended. The personal experiences with the crop of a number of alfalfa growers in different sections of the State are also given.

The inoculation and cultivation of alfalfa, A. M. Soule and M. Ferguson (*Virginia Sta. Bul. 154, pp. 79–117, figs. 5*).—This bulletin discusses alfalfa culture in general and gives specific directions for growing the crop in Virginia. The culture and harvesting of alfalfa, its uses and feeding value, and purposes and methods of soil inoculation are treated quite fully.

It is reported that alfalfa seeded September 15 on heavy red clay lands had developed roots from 2 to 3 ft. long by December 1, and that 2 years after planting roots 4 to 5 ft. long were secured. Preliminary investigations begun in 1904 showed the importance of soil inoculation and the advantages of using lime and phosphates on land intended for alfalfa. With inoculation a more uniform and denser stand was secured than without it. Turkestan alfalfa did not seem adapted to the conditions. Plats inoculated with *Melilotus alba* and those treated with barnyard manure produced a good growth. Foreign soil and that obtained at the station for inoculation gave practically the same results.

The improvement of corn in Connecticut, E. M. East (*Connecticut State Sta. Bul. 152, pp. 21, dgms. 2*).—The principles of corn breeding are discussed and complete directions given for the selection of corn and the establishment and management of a breeding plat for seed-corn production. The plan for planting the breeding plat to avoid inbreeding is taken from Illinois Station Bulletin 100 (E. S. R., 17, p. 26).

Methods of testing variability in corn, E. Davenport (*Illinois Sta. Circ. 101, pp. 7*).—This circular outlines means for accurately testing the range and extent of variability in any particular variety of corn.

By the method proposed the differences between varieties of corn as to variation in the length of ear are determined by accurate measurements of several hundred ears of each variety, and definite values for all the differences are obtained by submitting them to well-known mathematical processes. The methods of making these computations are explained, and the tendency of a variety toward a certain length of ear together with its variation from this tendency, is pointed out. The mathematical formulas are given in detail.

Corn improvement, A. T. Wiancko (*Indiana Sta. Bul. 110, pp. 77–120, figs. 14*).—Much of the matter in this bulletin has been previously published and reviewed (E. S. R., 16, p. 1071). Some new data are reported and the directions for managing a seed corn breeding plat are revised and amplified.

A germination test by the station of lots of seed corn from different sources and unequal as to the number of ears showed that on the basis of 5 kernels from each ear the percentage of ears having a perfect germination ranged from 34.2 to 98.5. In 5 lots the number of ears failing to germinate varied from 3 to 25.2 per cent. In addition to these tests, 5 lots showed a germination of from 91 to 95 per cent; 4 lots, from 83 to 87 per cent; and 6 lots, from 60 to 75 per cent.

In studying the effect of grading the seed on the uniformity of dropping by the planter, it was found that per 100 drops when middle kernels only were used 3 kernels were dropped 92 times as compared with 66 times when the whole ear was used, and 75 times when deep and shallow kernels were mixed. With deep kernels alone 3 were dropped 92 times and with shallow kernels alone, 95 times.

An examination of the stand in a number of corn fields showed a variation of from 65.6 to 89.6 per cent of perfection. The percentage of ear-bearing stalks was found to vary from 49.2 to 84.8.

The average yields of different breeding plats at the station in 1905 varied from 63.2 to 104 bu. per acre as calculated to 100 per cent stand. The yielding power of individual ears on the different plats showed marked variations.

Corn selection, F. W. CARD and M. A. BLAKE (*Rhode Island Sta. Rpt. 1905, pp. 200, 201*).—This line of work at the station has been previously described (E. S. R., 16, p. 766).

The seed planted in 1904, taken from the upper-ear lot, with 8 ears per stalk, produced 222 1-ear stalks, 291 2-ear stalks, 101 3-ear stalks, and 8 4-ear stalks. Owing to immaturity and poor development the seed used in 1904 and 1905 did not germinate strongly and gave an uneven stand. The results showed a decided reduction in the number of ears per stalk over those produced in 1903, and they indicate that the well-known cultural conditions are of greater importance than the selection of seed from the most productive parent plants.

Chemical studies of hops in 1904, J. SATAVA (*Ber. Vers. Anst. Brauindus. Böhmen, 1905, No. 11, pp. 40, map 1*).—The discussion is devoted mainly to the volatile oils, the hop acids and resins, and the hop tannin.

The soft resins are divided into α-resin and β-resin, according to their behavior toward alcoholic lead acetate solutions. The α-resin, containing one of the hop acids called humulon, forms a precipitate in such solutions, while no combinations with lead are formed in the case of β-resin, which is associated with lupulin. The principal points brought out by this study, according to the author, are that the intensity of pure hop aroma increases with the α-resin and humulon, and that the quantity of these substances in the product from long-established hop districts is quite constant in different places and in different seasons.

The book of the potato, T. W. SANDERS (*London: W. H. & L. Collingridge, 1905, pp. IX+222, pl. 1, figs. 108*).—This book gives advice on the different phases of potato culture in the garden and in the field, and in this connection the history, botany, and marketing of the potato are discussed. Directions for combating the diseases of the plant and its insect enemies are given, and varieties for the production of early, medium, and late crops, aggregating 269 sorts, are listed.

Rice growing in Arkansas, W. G. VINCENHELLER (*Arkansas Sta. Bul. 89, pp. 117–128, figs. 4*).—An experiment in rice growing under the direction of the station was begun in Lonoke County in Arkansas in 1902, and continued in 1904 and 1905.

The results of the first year demonstrated that rice would succeed on the prairie lands under irrigation. Ten acres were grown in 1904, one of the plats yielding at the rate of 75 bu. per acre. In 1905 the area was increased to 30 acres, but owing to unfavorable weather conditions only 25 acres were harvested. About 17 acres of Honduras rice yielded 53 bu., and about 8 acres of Japan 67.53 bu. per acre, the average for the 2 varieties being 57.8 bu.

The dates of planting, flooding, and harvesting, together with the yields, are shown in a table, and general directions for growing the crop under Arkansas conditions are given. The history of rice culture in the United States is briefly noted.

Sugar beet industry, R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 86–91*).—Statistics concerning the sugar-beet industry in Ontario are given, and a test of different varieties of sugar beets is reported. Of the large-growing varieties Giant White Feeding and Tankard Cream gave

the largest beets and the smallest amount of sugar. Improved Imperial, Rubensamen, and Mangel sugar beet proved equal in both sugar and purity to the Kleinwanzleben variety.

The results of experiments favor planting in rows 18 or 20 in. apart. The use of a small amount of nitrate of soda and fairly large amounts of sulphate of potash and superphosphate cause the beets to start quickly, and thus allowed thinning about 3 days sooner than where no fertilizer was applied. The fertilized plats gave a larger yield of beets and showed an increase of from one-half to 1 per cent in the sugar content.

Promoting the initial growth of the sugar beet, A. CSERHÁTI (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 36 (1905), No. 1, pp. 35–45; abs. in Centbl. Agr. Chem., 34 (1905), No. 8, pp. 530–532*).—The results secured by the author indicated that the growth of young sugar-beet plants is promoted by the use of the variety best adapted to the particular soil conditions, by the application in the drill of appropriate quantities of readily assimilable plant food in the form of commercial fertilizers, and by methods of soil preparation which enable the seed to be placed at uniform depths.

The von Kuffner method of seeding, as outlined, consists in rolling the land before planting, and attaching a small roller 12 cm. in width and weighing 40 kg. to the seed drill. This method assures a uniform soil condition as well as a uniform depth of planting.

Sugar and the sugar cane, N. DEERR (*Altrincham (Manchester), Eng.: Norman Rodger, 1905, pp. VIII+395+XIX, pls. 11, figs. 119, dgm. 1*).—This book is an elementary treatise presenting a general view of the cane-sugar industry. All the different phases of the production of the crop, as well as the details of cane-sugar manufacture and the management of the sugar factory, are discussed. Directions for the analysis of sugar-house products are also given. A bibliography containing 41 references is presented.

Progress report on the work of the Samalkot experimental sugar farm during 1903–1904, C. A. BARBER (*Dept. Land Rec. and Agr. Madras, Agr. Branch Bul., Vol. III, No. 51, pp. 21, pls. 5*).—The culture of sugar cane in the Gôdâvari delta is described and the results of experiments at the station discussed.

Among the different varieties of cane tested Red Mauritius gave the best results, the larger yield of cane being due not to a great tillering power but to the weight of individual canes. Vansi tillered most and had about 3 times the number of canes shown by Red Mauritius. This season the Red Mauritius produced a fine even stand when the whole plant was cut up for seed. Some varieties, as the Seema, can only be grown from tops, and an experiment with the Yerra cane gave almost twice as many shoots from cuttings taken from the upper ends as from the same number of cuttings taken from the lower ends of the cane.

Results of experiments with varieties of canes, J. B. HARRISON (*Georgetown, Demerara; Bd. Agr., 1905, pp. 9*).—Variety tests with sugar cane were made on a large number of plantations, and the results secured indicated that the varieties raised and selected locally were, in general, good ratooning canes and of greater merit than the imported Barbados varieties Sealy and B. 147. The estimates of the milling qualities of the different varieties were not concordant. Selections D. 625, D. 145, and D. 109 showed well-marked ratooning qualities and are recommended to cane farmers for trial. On one estate seedling varieties gave a yield of 7 per cent and on another of 30.7 per cent greater than Bourbon. D. 74, D. 78, and White Transparent showed signs of falling off in their yields and are no longer recommended for cultivation.

Varieties of tobacco seed distributed in 1905–6, with cultural directions, A. D. SHAMEL and W. W. COBEY (*U. S. Dept. Agr., Bur. Plant. Indus. Bul. 91, pp. 40, pls. 9*).—This bulletin treats of the tobacco seed distribution by this Department conducted for the purpose of testing the adaptability of the different varieties to conditions of soil and climate in various tobacco-growing sections. Descriptions are given of varieties of cigar wrapper, cigar filler, pipe, and plug tobaccos, and directions for the culture of these different classes of tobacco are presented. Directions for saving seed and securing good seed are also given.

Comparative values of different grades of wheat of crops of 1903 and 1904, R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 76–82*).—In this study the percentage yield of flour; the weight per measured bushel; the percentage of moisture, acidity, proteids, and gluten, and the yield of bread per 100 lbs. of flour was determined in samples of wheat graded as No. 1 Hard and Nos. 1, 2, 3, and 4 Northern.

The percentage of protein in the flour from the various grades of the 1903 crop ranged from 9.98 to 11.13, while in the 1904 samples the extremes were 9.29 and 12.15. In the baking test a sample of No. 4 Northern produced the quickest working dough and also made the largest loaf, while a sample of No. 1 Hard made the smallest. This corresponded with the strength of the flour as indicated by the gliadin content. In the production of a white loaf No. 4 Northern, the lowest grade, was not equal to the higher grades.

In general the milling, chemical, and baking tests did not show any very wide differences in the products of the samples, but in yield of flour and in color of bread the lower grades were inferior while in strength and yield of bread no great variation was apparent.

The total proteids and the alcohol soluble proteids in samples of 6 varieties of spring and 20 varieties of winter wheat are reported. It is considered that although the data secured give a comparison of the probable strength of the various wheats, actual baking tests are required to show definitely the relative value of the different varieties.

Determination of the germinative power of grains, O. QVAM (*Landw. Vers. Stat., 62 (1905), No. 6, pp. 405–443, fig. 1, dgm. 1*).—The sources of error in the common method of determining the germination in grain samples, which consists in basing the results on the number of sprouted grains in a sample, are pointed out and a new method, considered more accurate, is described.

This new method, called the weight method, is based upon the weight of the dry matter in the young plants exclusive of the roots and is believed to be more accurate and reliable in showing the quality of the seed. Comparisons of the two methods were made and the variations in the results noted. The weight method gave, in general, quite uniform data. In seed of poor quality the variations were much greater in determinations by the common method than in those by the new method, but as the quality of the samples improved the differences between the two methods were reduced.

The grains, like all grasses, develop their permanent roots from the crown. The first roots thrown out by the seed are only temporary, and hence the development of the plant depends upon the permanent roots. The author points out that the stooling of grains botanically considered is the branching of the plant, and concludes from this and the foregoing facts that the stem controls the growth of the roots as well as the number of shoots, and that for this reason the value of the seed should be judged by the vigor of the portion of the plant above ground.

Different varieties of the same species were found to vary in the amount of plant substance produced on the surface of the ground. It was noticed that

in the case of oats the Duppau variety produced a greater weight than Ligowo, and this variety a greater weight than Tartar King. It is considered probable that these differences are due to the character of the hull and the kernel.

The personal factor in making the determinations is largely removed by the weight method, thus leading to uniformity in the results of different laboratories; and the sources of error are comparatively small, and no greater in samples of poor than in those of good quality. The method admits of the use of larger samples, and in this way tends toward greater accuracy. From a botanical point of view it has the preference over the germination method. It admits of simplification in determining purity, and the results refer not only to the number of germinable seeds in a sample but also to their viability, while the germination method simply shows the number of living seeds.

The results of field experiments seem to confirm the superiority of the method. Its application is described in detail.

Report of Danish seed control [station], 1903–4, K. DORPH-PETERSEN (*Copenhagen, 1904, pp. 56*).—A summary of the activities of the station during its 33d year is given and the results of examinations of farm and garden seeds for the year and for the preceding decade, with notes on the origin of the seed in the Danish market, the occurrence of noxious weeds, germination tests with seed of Danish wild plants, water content of seed, etc., are reported.

Experiments in progress since 1900 show that plantain and charlock seed retain their viability nearly without deterioration when buried in the ground. In another experiment 153 gm. of plantain and 186 gm. of camomile seed were fed to a cow, the number of seeds in the excrement determined, and their viability tested. About 86 per cent of the plantain seed and 33 per cent of the camomile seed were recovered. The viability of the plantain seed as shown on 2 different days was 62 and 53 per cent as compared with 89 per cent for the seed as fed, and of the camomile seed, 84 and 59 per cent as against 94 per cent for the original seed.—F. W. WOLL.

Rules and regulations governing the Colorado Patterson seed selection competition, W. H. OLIN and W. L. CARLYLE (*Colo. Agr. Col. Bul., 5. ser., 1905, No. 2, pp. 11, fig. 1, dgm. 1*).—The rules and regulations governing this competition are given, with explanations as to the way the awards are to be made and instructions for conducting the work.

HORTICULTURE.

Report of the horticultural division, F. W. CARD and M. A. BLAKE (*Rhode Island Sta. Rpt. 1905, pp. 197–219, pls. 4*).—This covers the results secured at the station in various cultural and breeding experiments with vegetables and fruits. Some notes on the apple maggot and on corn selection are noted elsewhere in this issue.

A severe wind storm occurring in September, 1904, gave an opportunity to estimate the relative resistance of some 28 varieties of apples to wind. The varieties York Imperial, Tuft Baldwin, Seek-no-further, Pomme Gris, Pewaukee, Mann, Northwestern Greening, and Palmer appeared to have the least resistance, while little or no fruit was blown from such varieties as Winesap, Roxbury Russet, Canada Red, Genet, and Ben Davis.

As a result of 6 years experimental work with bush fruits the conclusion is reached that the climatic conditions prevailing at the station are decidedly unfavorable to the growth of bramble fruits. It is thought that the great humidity caused by proximity to the ocean is one of the causes of injury to

this fruit. Experiments with these crops have therefore been practically abandoned.

A plan is given of a market-garden rotation experiment underway, the object of which is to determine whether it is possible to grow market-garden crops successfully without stable manure by means of a rotation in which cover crops can be used for maintaining the humus in the soil. The first year's rotation will consist of corn followed by beans on one plat and beans followed by corn on another plat. Some data secured on these plats in 1904 relative to the yield and appearance of the different crops are tabulated.

A common complaint from greenhouse men is that soil sterilization seems to destroy the life of the soil. A number of experiments were therefore undertaken to determine the growth of lettuce and radishes on (1) unsterilized soil, (2) soil sterilized and handled while hot, (3) soil sterilized but not handled till cold and dry, (4) soil sterilized, handled cold, and later sprinkled with garden soil, and (5) soil sterilized, handled cold, and nitrate of soda used.

The first year of the experiment the largest yield of both lettuce and radishes was obtained on the unsterilized soil, followed by the soil sterilized but not handled till cool and dry. The second year the largest yield of radishes was obtained on the sterilized soil to which nitrate of soda had been added, followed by the unsterilized soil, while with lettuce the largest yield was secured on the unsterilized soil and the smallest yield on the sterilized soil sprinkled with garden soil.

A number of vegetables were grown under tent covering to determine the effect of this partial shade. With transplanted lettuce grown under the tent the average weight per head was 6.57 oz., while the average weight per head of lettuce grown outside the tent was 6.19 oz. When seed was used, the weight of the heads grown inside the tent was 14 oz. and outside the tent 9.8 oz. It was found much easier to transplant lettuce under the tent than in the open. It grew faster under the tent up to the point of heading, but did not form as firm a head as those grown outside, nor was the quality quite as good.

Cauliflower grown under the tent made a better growth throughout the season than when grown outside. The plants were higher and the growth of the leaves much stronger, while the yield was 140 per cent greater inside the tent than outside. Under the tent the cauliflower was less attacked by insects and the heads were not so likely to discolor if not tied up just at the proper time.

With celery there was a smaller percentage of waste from that grown under the tent than from that grown in the open and the stalks were a little softer. Celery grown outside was a little shorter, more stocky, and slightly better in quality than that grown inside, and was more subject to rust.

Some data are given on the temperature inside and outside the tent, which shows that inside the tent it ranged from 1° to 12° cooler than outside, the average being 5.36° F. cooler.

A large number of strawberry seedlings have been grown, and the scale of points adopted in scoring plants and fruit with a key to the records of the plants is given. The purpose of the breeding work with strawberries is to secure late ripening sorts coupled with other good qualities. Crosses have been made on the wild plants for the purpose of introducing desirable flavors.

Report of the professor of horticulture, H. L. HUTT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 143-160, figs. 5*).—A general outline of the work of the year with orchard and small fruits, vegetables, and flowers, with data on the results obtained from the use of a large number of different

plants as orchard cover crops and on tests of varieties of currants and tomatoes.

Among currants the White Grape has proved the most productive variety of 46 grown. Of the red varieties Red Cross, Victoria, and Fay have proved most satisfactory. Naples has been the most productive of the black currants, but is not equal in size and quality to Champion and Black Victoria. The heaviest yielding tomatoes in 1905 were the Dominion Day and Earliana, the former of which produced 36 lbs. of fruit per plant and the latter 32 lbs.

Vegetable growing in Alaska, C. C. GEORGESON (*Alaska Stas. Bul. 2, pp. 46, pls. 4*).—An account of the climatic and soil conditions of various sections of Alaska with general observations relative to shelter belts, drainage, fertilizers, hotbeds and cold frames, seed testing, and detailed directions for the culture of vegetables based on the results of experimental work.

Heavy rainfall is stated as the chief drawback to successful farming and gardening in the coast regions. At Sitka the average rainfall is 90 in. The temperature rarely exceeds 80° F. in summer or falls below zero in winter. In the interior the summers are short but quite warm and the winters prolonged and severe. The rainfall is also light, and it is still a question whether irrigation may not be necessary in some of the drier regions.

The ground in the winter is frozen to an unknown depth. When cleared and exposed to the sun it gradually thaws. The ice is not a drawback to vegetable and grain growing after it recedes 2 or 3 ft., but rather an advantage, as it furnishes moisture to the growing plants and in dry seasons acts as a substitute for irrigation.

A peculiarity of Alaskan soil is that the vegetation turns into soil slowly and imperfectly and generally gives a very acid reaction. This is particularly true of the soils of the coast regions. It is greatly benefited by liming. Suggestions for burning native limestone are given. In the interior there is a great variety of soils, but they are generally of a sandy, gravelly, or light loamy character.

The following vegetables, for which detailed cultural directions are given, can be grown in Alaska:

"Group I.—Radish, mustard, turnips, kale, lettuce, orach. These can be grown throughout the whole coast region and in the interior northward of the Arctic Circle, nearly to the Arctic Ocean, in favorable seasons and in picked localities.

"Group II.—Carrots, parsnips, parsley, peas, cress, cabbage, cauliflower, broccoli, Brussels sprouts, kohl-rabi, onions, spinach, endive, leek, beets, potatoes, rhubarb, and among the herbs, caraway, catnip, marigold, mint, sage, thyme. These can be grown everywhere in the coast region in Alaska, and in the interior nearly to the Arctic Circle if the gardens are selected with due reference to shelter and exposure to the sun.

"Group III.—Asparagus, beans, celery, cucumber, squash, salsify. These can be grown in favorable seasons if planted in warm spots and given the proper care and protection.

"Vegetables which can not be grown in Alaska out-of-doors under ordinary garden culture, though they are common in the States, are: Sweet corn, melons, tomatoes, peppers, eggplant, okra, pumpkins."

Tomato culture, C. F. AUSTIN and E. W. HALSTEAD (*Estac. Cent. Agron. Cuba Bul. 4, pp. 16, pls. 8*).—Popular directions based on the results of experimental work at the station are given for the culture of tomatoes.

Many varieties were tested during the year and it was shown that first-class tomatoes can be grown in Cuba during all of the winter months. The tables included in the bulletin show the average yield per plant and per acre for the different varieties. Brief descriptive notes of 30 of the most promising varieties

are given. The following varieties mentioned in the decreasing order of productiveness are recommended: Matchless, Livingston Beauty, Acme, Earliana, Thorburn Earliest, Frogmore Selected, Rosalind, and Lemon Bush.

Tomato growing, R. THOMSON (*Jour. Jamaica Agr. Soc., 9 (1905), No. 12, pp. 443, 444*).—Tomato growing on a commercial scale for export to England and America is stated to be a success on the island. Tomatoes grown by the author on a quarter of an acre sold for nearly $200. Tomatoes shipped to London packed in fibrous material arrived there in good condition, and the fruit was considered equal to the best grown on the Canary Islands, from which place England secures large supplies.

Seed distribution of 1904 and for 1905, B. D. HALSTED (*New Jersey Stas. Bul. 191, pp. 19, pls. 4*).—In connection with the plant-breeding work of the stations a number of varieties of vegetables have been originated, and seeds of these have been distributed more or less freely throughout the State.

The present bulletin is made up largely of the reports of growers who have planted these various seeds. Very flattering results have been obtained with a number of these vegetables, more particularly the Voorhees Red sweet corn, Station bush Lima beans, Station yellow tomato, and the Station eggplants. The Malakhov sweet corn distributed by the station has proved a very satisfactory variety. Notes are given on further experiments in crossing Malakhov with Crosby and Premo sweet corns and in crossing Black Mexican and Country Gentleman.

With the latter varieties of sweet corn black appears to be a predominating color, and the crosses quite closely follow the law developed by Mendel in the case of peas. The Magnerosa tomato, secured by crossing Magnus and Ponderosa, is a nearly smooth and remarkably meaty tomato without the tendency to the green solid center sometimes seen in the Ponderosa. It is recommended for the main crop. A number of other crosses obtained with tomatoes are mentioned and described as well as some with squashes. A list of 20 varieties of seeds offered for distribution is appended.

Fruits for home orchards and gardens, T. V. MUNSON (*Texas Farm and Ranch 24 (1905), No. 51, p. 4*).—The author presents a table in which the adaptability of different varieties of orchard fruits, small fruits, and grapes to various classes of soils in Texas, New Mexico, Oklahoma, Indian Territory, Arkansas, and Louisiana is noted. The table shows in condensed form the results of the author's thirty years' experience in Texas as a fruit grower.

Fruit and fruit utilization, H. RÜHLE (*Ztschr. Angew. Chem., 18 (1905), Nos. 47, pp. 1852–1856; 48, pp. 1892–1900; 49, pp. 1941–1946*).—An extensive account of the fruit industry in Germany, including statistics on exports and imports, with details of analyses of a large number of orchard and small fruits, including some tropical fruits.

Details are given regarding chemical methods of fruit analysis, with a discussion and data on the changes which take place in fruits in after ripening. A discussion is also given of the normal amount of salicylic and boracic acids in many fruits. Extensive bibliographical references are included.

Pruning fruit trees, W. PADDOCK (*Colorado Sta. Bul. 106, pp. 15, pls. 2, figs. 13*).—Popular directions for pruning orchard fruits.

Blooming periods of tree fruits, H. L. PRICE (*Virginia Sta. Bul. 155, pp. 130–142*).—A general discussion is given of the causes of unfruitfulness, the value of mixed plantings, and the necessity of selecting trees for pollenizing each other which have the same period of bloom.

The bloom chart given is based on 13 years' observations at the station and shows the average blooming period during this time of the varieties of the various groups of plums, cherries, pears, crab apples, and apples. Among the

causes of unfruitfulness rapid wood growth of young trees, attack of bloom by fungi, long-continued rain during the blooming period, and self-sterility are mentioned.

Freezing of fruit trees, F. H. HALL and H. J. EUSTACE (*New York State Sta. Bul. 269, popular ed., pp. 8*).—A popular edition of Bulletin 269 of the Station (E. S. R., 17, p. 558).

Notes on varieties of apples, C. C. NEWMAN (*South Carolina Sta. Bul. 109, pp. 38, figs. 31*).—A large number of varieties of apples have been grown at the station for 12 years, the last 7 of which the trees have been in bearing. Many of these are varieties suited to supply fruit continuously from June to the first of April. Detailed descriptions and drawings are given of 30 of these varieties and recommendations as to the best summer, autumn, and winter varieties to plant in mountain regions, hill regions, and the pine belt.

Handling the apple crop, H. H. HUME (*Bul. N. C. Dept. Agr., 26 (1905), No. 9, pp. 22, figs. 9*).—Popular directions for harvesting and packing apples for shipment, with apple-shippers' rules regarding the standard barrels and requirements for different grades of apples.

Horticultural section, W. J. PALMER (*New Zeal. Dept. Agr. Ann. Rpt., 13 (1905), pp. 278–294*).—Besides an account of the work of the year, a list is given of the aphis-resistant and blight-proof varieties of apples grown in New Zealand.

About new hardy oranges, H. E. VAN DEMAN (*Rural New Yorker, 65 (1906), No. 2921, pp. 40, fig. 1*).—The author discusses the work of J. L. Normand, Marksville, Louisiana, who is breeding new varieties of hardy oranges.

The hardy variety, *Citrus trifoliata*, is used as the male parent. Thus far one variety has been obtained which is considered of sufficient value to be placed on the market. This has been named "Carnegie," and is a cross with the Boone which is a very early orange. The Carnegie averages over 2 in. in diameter, and is of good flavor, though not as good as really choice oranges.

Timing of bananas (*Jour. Jamaica Agr. Soc., 9 (1905), No. 12, pp. 453–455*).—About a million bunches of bananas are now exported yearly from Jamaica. The best prices are secured for those marketed from the beginning of March until the end of June. Planters are therefore urged to so time their suckers as to produce fruit during this period instead of the more natural season of July to October.

Bananas and pineapples, Y. HENRY (*Bananes et Ananas. Paris: Augustin Challamel, 1905, pp. 141, figs. 19, maps 12*).—A treatise on the production and commerce of bananas and pineapples in French Guiana.

Preserving fresh berry fruits, T. ZSCHOKKE (*Landw. Jahrb. Schweiz, 19 (1905), No. 9, pp. 617–619*).—Unripe gooseberries were washed in boiled water that had been allowed to cool, then put in cans and covered with boiled water which had become cool. The cans were then sealed and stored for eight months, at a temperature of about 16° C. At the end of this time the cans were opened. The water in which they were preserved had remained clear. There were no settlings in the bottom of the glasses, but the water had a very acid taste. The berries themselves were of full size, hard, and of a green-white color. They tasted almost like fresh unripe berries. The berries which originally had contained 27.2 per cent acid and 3.91 per cent sugar, contained at the end of the experiment 18.9 per cent acid and 2.72 per cent sugar, a loss of about 30 per cent of both constituents.

For such purposes as sauce where the water might be used along with the berries, there would be no loss, but for jelly-making purposes it was found that when only the berries were used the jelly would not set. Cranberries when

preserved in the same manner as the gooseberries kept in good condition for a year.

Does the acid content of berry fruits decrease when cooked with sugar? W. KELHOFER (*Landw. Jahrb. Schweiz, 19 (1905), No. 9, pp. 601, 602*).—Cooking unripe gooseberries with sugar was not found to decrease the percentage of acid in the fruit. Earlier experiments by the author had shown a similar result with orchard fruits.

Changes in unripe gooseberries during after-ripening, W. KELHOFER (*Landw. Jahrb. Schweiz, 19 (1905), No. 9, pp. 600, 601*).—Some data relative to the changes which take place in the after-ripening of gooseberries was obtained by the author.

Earlier investigations had shown that with black currants, picked when slightly green and kept for a few days, there was an increase in sugar and a decrease in acid content during the after-ripening. Gooseberries do not appear to act in the same manner. Picked June 24, when green, they contained 3.91 per cent of sugar and 27.2 per cent of acid. When kept at a temperature of 15.2° C. for six days, they had taken on a dark color and contained 3.42 per cent of sugar and 25.5 per cent of acid, a decrease in both cases during after-ripening.

Report of the viticulturist, R. BRAGATO (*New Zeal. Dept. Agr. Ann. Rpt., 13 (1905), pp. 300–312*).—An outline of the work of the year is given. This, at the station, has consisted mainly in the propagation of American vines for resistant stocks.

Shallow culture of grapes, L. DEGRULLY and L. RAVAZ (*Ann. École Nat. Agr. Montpellier, n. ser., 5 (1905), Nos. 1, pp. 19–87; 2, pp. 148–188, figs. 34, dgms. 6*).—A review of the literature on this subject with the results of elaborate experiments to determine the effects of deep and shallow cultivation on root and vine growth of grapes.

Among the conclusions drawn are the following: Young vines from the time of setting out until the age of 3 years should receive ordinary good cultivation. The first roots are usually deep, and it is of prime importance that cultivation be such as to facilitate aeration of the soil to the depth of these roots. For older vines shallow culture is preferable on all compact, moist, or average soils. It is equally advantageous in sandy soils of the coast which are very dry at the surface but where the water table is high. On the other hand, in dry, gravelly, very permeable soils, where the water table is low and consequently the roots tend to establish themselves in the lower beds of soil, deep culture ought to give better results than systematic shallow culture. Diagrams are given showing the root development of vines on different soils cultivated to different depths.

The affinity of French scions with Rupestis du Lot in calcareous soils, E. ZACHAREWICZ (*Rev. Vit., 25 (1906), No. 629, pp. 17–20*).—The yields obtained during 5 years with five varieties of European grapes grafted on Rupestis du Lot are tabulated. Both the yield of fruit and the alcoholic content of the wine were above normal. The shoots on some of the vines in the experiment were pruned to a length of fifty to sixty centimeters. These vines yielded practically double the amount of wine obtained from vines pruned back to 2 buds.

Tests of varieties of grapes, W. KELHOFER (*Landw. Jahrb. Schweiz, 19 (1905), No. 9, pp. 598–600*).—In tests of 28 white and 14 red varieties of grapes in 1903, for wine making, the average sugar content of both kinds was practically the same, but the acid content averaged about 3 per cent higher in the red than in the white varieties.

Relation of sugar to the weight of the must and to the acid in grape juice at the Wädenswil Experimental Vineyard during the past 14 years, W.

KELHOFER (*Landw. Jahrb. Schweiz, 19 (1905), No. 9, pp. 596–598, dgm. 1*).—A table is given showing the composition of the must as regards sugar and acid content for each crop of grapes grown at the station since 1891. The data show that as the percentage of sugar increased in favorable years, the acid content decreased in similar manner.

The Persian walnut, J. G. RUSH (*Ann. Rpt. Penn. Dept. Agr., 10 (1904), pp. 537–539*).—Most of the Persian walnuts grown in the East, the author states, are seedlings. It is only occasionally that one of these seedlings is productive. It is believed that if seedlings are grafted from these productive sorts, the growing of Persian walnuts would become a profitable industry in many eastern States. In the author's investigation only 4 per cent of the Persian walnut trees observed were worthy of propagation.

Queensland nut, W. J. ALLEN (*Agr. Gaz. N. S. Wales, 16 (1905), No. 10, pp. 1026–1028, figs. 3*).—Brief descriptive account of this nut, *Macadamia ternifolia*, also known as Australian hazelnut. The illustrations show the general outline of the tree and the character of the fruit at different stages of growth.

Coleus with edible tubers, A. CHEVALIER and E. PERROT (*Vég. Utiles Afrique Trop. Franç., 1 (1905), No. 1, pp. 100–152, pls. 8, figs. 15*).—Descriptions are given of the edible species of coleus encountered in tropical Africa with illustrations of the plants and tubers and of cross sections of the tubers and of the starches contained in the different species.

It appears that in the west and central portions of French Africa four species of coleus are cultivated for their tubers. The most prominent of these is *Coleus rotundifolius* or Madagascar potato. This species it appears is also cultivated under different names in Java, Ceylon, and the East Indies. There are a number of varieties of this species. *C. dazo* is also cultivated on a large scale in Central Africa producing a tuber which differs considerably from the Madagascar potato and which it is believed is destined to take a prominent part in the future of tropical agriculture.

A third species *C. langouassiensis*, cultivated locally in the vicinity, appears to be the heaviest yielding of the three varieties noted. It is believed that all of these three species will prove of great importance to Europeans living in tropical countries. A minor species is *C. brazzavillensis*. Historical and botanical descriptions are given of a number of other species of coleus. Analyses with reference to food value are given for three of the most important species with cultural suggestions. Yields of 30 to 40 tons of tubers per hectare are reported.

Carnation breeding, H. F. HALL (*Amer. Florist, 26 (1906), No. 921, pp. 6, 7*).—The season from October 15 to December 1 is considered the most favorable for carnation breeding. Some varieties of carnations from which it is difficult to obtain pollen have been induced to produce pollen by growing them in pots in winter and keeping them rather dry.

In transferring the pollen to pistils the best results have been obtained by using a strip of ordinary blotting paper 3 or more inches long and about one-half inch in width, one end being cut with scissors to resemble a sharpened pencil. The point, however, is slightly fluffed to enable it to take up and hold the grains of pollen until lightly rubbed over the stigmatic surface of the pistil.

The objects and plan of the Heeleaka Experimental Station, H. H. MANN and C. M. HUTCHINSON (*Indian Tea Assoc. [Pamphlet] 2, 1905, pp. 11, pls. 2*).—An outline of the fertilizer, green manuring, pruning, and plucking experiments which are being carried on under the direction of the authors at this tea station. The station has been located at Heeleaka, near Moriari, Assam.

Society for Horticultural Science (*Amer. Florist, 26 (1906), No. 924, pp. 147–149*).—Somewhat extended abstracts are given of the papers presented at the annual meeting of the society held in New Orleans, December 29, an account of which has been given (E. S. R., 17, p. 616).

FORESTRY.

The forester, J. NISBET (*Edinburgh and London: William Blackwood & Sons, 1905, vols. 1, pp. XX+506; 2, pp. XV+642, figs. 285*).—These two volumes are based on the sixth edition of *The Forester*, issued in 1894, and are intended to serve as a text-book of British forestry and arboriculture. The 3 chapters, into which part 1 is divided, treat in a general way of the history of forestry in Great Britain, the present condition of the woodlands, technical forestry education, and the economic importance of forestry. Part 2, consisting of 2 chapters, is devoted to British sylva; and part 3, made up of 7 chapters, to sylviculture.

Wood, J. BEAUVERIE (*Le Bois. Paris: Gauthier-Villars, 1905, vols. 1, pp. XII+1–704; 2, pp. 705–1402, pls. 16, figs. 485*).—This work treats of the structure and qualities of timber, the composition and chemical properties and the general character and physical properties of wood, forests, lumbering, timber trade, defects in timber due to faulty methods of growth and to fungus, insect and other animal enemies, preservation of wood, wood essences, such as resin, native or naturalized woods, cork, wood production of the world, woods of the French colonies, and the utilization of wood.

The lumber industry (*Tradesman, 54 (1906), No. 9, p. 94*).—Statistics are given showing the States in which timber land is owned by lumbermen, capital invested, and number of acres. The average quantity of merchantable timber per acre and the estimated quantity of merchantable timber in feet are also given.

Evergreens; how to grow them, C. S. HARRISON (*St. Paul, Minn.: Webb Pub. Co., 1906, pp. VI+95, figs. 19*).—Popular directions for growing evergreens in the prairie States.

Artificial fertilizers in forestry, HENZE (*Deut. Landw. Presse, 32 (1905), No. 94, pp. 783–785, figs. 9*).—Data with illustrations are given showing the much more rapid growth of seedling forest trees with than without fertilizers.

Plan for the manuring of forests, SCHWAPPACH (*Ztschr. Forst u. Jagdw., 38 (1906), No. 1, pp. 49–52*).—An extensive plan is given by which different green manures and fertilizers may be tested comparatively for forests.

The water content of diluvial forest soils, E. RAMANN (*Ztschr. Forst u. Jagdw., 38 (1906), No. 1, pp. 13–38*).—An account of extensive experiments on forests and cut-over areas to determine the water content of such soils and the effect on water content of different methods of cultivation. The experiments were carried out in 1894–5, and the details are given at length in tabular form. Among the most important conclusions are the following:

Under otherwise like conditions the water content in soils heavily timbered is less than in the soils of cut-over areas. Water content is only one of the important factors in tree development. Soils with like water content may be very different and soils with a very different water content may belong to the same yield class. Cultivation of sandy soils increases the water content considerably. The influence of cultivation is felt only over the cultivated areas. Neighboring areas show no noticeable change. The surface layer prominently influences the water content of sandy soils. This is particularly true of the humus layer on

mineral soils, which during the period of tree growth greatly lessens the water content of the soil.

A study of the form and development of the roots of the pine and other trees, A. Tolski (*Trudui Opuitn. Lyesn., 1905, No. 3, pp. 1–62, pls. 6, figs. 18*).—A study of the root system of trees under varying soil and topographic conditions was undertaken by the author with a view to ascertaining the causes of the decay of pine plantings in the Buzuluk Forest, in the government of Samara. The investigations were begun in 1903 and have been carried on with pines 3 to 100 years old, and with birches, aspen trees, and linden.

Among the conclusions are the following: One of the main factors which exercises a more or less considerable influence on the structure of the roots is the depth to moisture. With humidity in close proximity, then, simultaneously with the development of the superficial roots, the development of the vertical ones takes place. If, on the contrary, the humidity is at a considerable depth then the development of the superficial roots greatly predominates. The length of all the roots is in general much greater in the leafy trees than in the pine, the linden being an exception. With pines it was observed that the root system on poor soils was much more developed than on fertile soils. The investigation will be continued.—P. FIREMAN.

Root pruning forest trees (*Österr. Forst u. Jagd Ztg., 23 (1905), No. 46, p. 386, figs. 5*).—Stub root pruning has been practiced by the author with a number of different species of seedling forest trees during the last 2 years with very good results. Illustrations are given showing the character of the root system developed when thus pruned according to the Stringfellow method, and it is thought this method of treatment may have application in forestry practice.

Root pruned trees (*Rural New Yorker, 64 (1905), No. 2918, p. 931, fig. 1*).—As the result of extensive experiments in planting stub pruned peach trees, the author is convinced that the long roots usually left on trees at transplanting are useless.

He does not prune back to the extent recommended by Stringfellow and use a crowbar in setting out the trees, because of the difficulty of packing the soil firmly under the roots of the trees in such holes. He thinks it better to leave short stubs at the sides of the roots, pruning them from the under side. A hole is then dug just large enough to hold the roots without cramping and the earth pounded and packed solidly around them. An illustration is given showing the very satisfactory development of roots on trees thus pruned.

Note on increment of spruce in West Virginia and fire losses, B. E. Fernow (*Forestry Quart., 3 (1905), No. 4, pp. 346–348*).—On a property of 75,000 acres 3,000 acres are cut each year. A portion of the area was burned over in the seventies and the new growth is about 25 years old.

From measurements of this growth the author shows that during the 25 years that would be necessary to cut over the whole area about 8 cords of wood per acre would be produced on the first area cut. If fire could be kept out of the forest entirely it is estimated that after the whole tract had been lumbered over an annual harvest of 28,000 cords of wood, worth then probably more than $100,000, could be secured for at least 25 years if not continuously. On this basis it is believed that it would be financially profitable to provide for immediate fire protection.

Notes on the rate of growth of red cedar, red oak, and chestnut, H. S. Graves (*Forestry Quart., 3 (1905), No. 4, pp. 349–353*).—Tabulated data are given showing the diameter and height of these trees at different ages.

A study of 23 red cedar trees at New Haven, Conn., showed that a tree growing in the open required 30 years to yield a post 6 ft. long and 4 in. in diameter at the top end; that a tree 40 years old might yield 2 such posts;

and that from a tree 50 years old, 1 post 10 ft. long and 1 post 6 ft. long could be obtained. The data for red oak showed an average diameter of 3.5 in. and a height of 36 ft. at 20 years of age and a diameter of 10.4 in. and a height of 70 ft. at 60 years of age.

In the case of chestnut sprouts it was found that a pole 30 ft. long and 6 in. in diameter could be grown in the open in 30 years and in the forest in 40 years. It is thought probable that in 50 years 100 to 150 trees per acre at least 13.7 in. in diameter at breast height could be produced. If 125 trees straight enough for poles could be secured in 50 years a stumpage value in poles alone of $125 would be attained. The tables given show the rate of growth of chestnut sprouts in New Haven, Conn., and at Milford, Pike Co., Pa.

On the rate of growth of birch in the mountain regions of Jämtland, Sweden, G. ANDERSSON (*Skogsvårdsför, Tidskr., 3 (1905), No. 11, pp. 417–422*).—Determinations in 3 different districts at altitudes ranging from 600 to 700 m. showed that the average increase in diameter per year for birch was 1.45, 2.45, and 3.05 mm. Fuel wood of 15 to 20 cm. diameter will accordingly require the following periods for full growth: 50 to 65, 60 to 80, and 100 to 140 years for the different districts, respectively.—F. W. WOLL.

Instructions for making forest maps and surveys, G. PINCHOT (*U. S. Dept. Agr., Forest Serv. [Circ.], Oct. 5, 1905, pp. 10*).—Directions for the use of various surveying and map-making instruments and of different colored pencils and signs which are to be used in the Forestry Service to secure uniformity in map work.

Report of the lecturer in forestry, E. J. ZAVITZ (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 222–227, figs. 6*).—A general outline of the work of the year, with a list of the various species of trees growing in the college plantation and nursery.

Forest belts of western Kansas and Nebraska, R. S. KELLOGG (*U. S. Dept. Agr., Forest Serv. Bul. 66, pp. 44, pls. 6, map 1*).—A study was made of the forests of western Kansas and Nebraska and eastern Colorado, included between the ninety-ninth and one hundred and fourth meridian, and the northern boundary of Nebraska and southern boundary of Kansas and Colorado. This area includes about 109,000 square miles. The physical conditions of the country are first noted, followed by a discussion of the natural forest types of the region.

In Kansas and Nebraska the natural forest growth is limited to the river courses and a few upland areas of pine and cedar. The pine type is chiefly prominent in northwestern Nebraska, while the valley type is the common forest type of the river courses in Kansas and Nebraska. While the pine type is of the greater economical importance, the valley or broadleaf type is of interest to a much larger number of people. Most of the pine forests of value have been cut away and destroyed.

A study was made of the reproduction of rock pine. In one instance, out of a total of 1,509 seed gathered from fallen cones, only 20 were good, and out of 2,253 seed from green cones only 1 in 7 was good. The chief cause of the defectiveness in these cases appeared to be in the failure of the seed to develop.

Tables are given showing the rate of growth of young rock pine in different counties of Nebraska. Red cedar has been quite completely cut out, but where such trees exist the reproduction is generally good and much larger than that of pine. The principal enemies to tree production are stock, fires, and to some extent the tip borer of pine.

The prevailing species of timber along the river courses are white elm, hackberry, red mulberry, green ash, box elder, cottonwood, and almond-leaf willow. The number of these trees on various sample areas in different counties of

Kansas are given, together with data as to their minimum and maximum diameters breast-high. The rate of growth of white elm, green ash, hackberry, and bur oaks in different localities is also shown in tabular form. On 31 sample areas examined in western Kansas the reproduction of the valley type was good in but 6 instances. In 6 more it was fair, while in the remaining 19 it was very poor, due in a large measure to unrestricted grazing.

A general discussion is given of how forest extension is brought about, with brief descriptive accounts of 28 species of trees found in western Kansas and Nebraska.

Forest reserves in Idaho, G. PINCHOT (*U. S. Dept. Agr., Forest Serv. Bul. 67, pp. 90, figs. 5, map 1*).—This bulletin contains copies of the correspondence and papers relating to the creation of forest reserves in Idaho.

Forestry in Maryland, W. D. STERRETT (*Forestry and Irrig., 11 (1905), No. 12, pp. 571–580, figs. 9*).—A discussion of the general forest conditions in the Appalachian, Piedmont Plateau, and Coastal Plain regions of Maryland, and of the progress of forestry in these same regions. About two and one-half million acres, or 40 per cent, of the total land area of the State is woodland, but less than 1 per cent of the wooded area is virgin forest. Most of the second-growth forests are under 150 years of age. The chief lumber tree is yellow pine.

Report of the superintendent of forests, W. F. FOX (*N. Y. State Forest, Fish and Game Com. Ann. Rpt., 10 (1904), pp. 9–34, pls. 12*).—A general review of the work of the year 1904, relative to control of forest fires, reforesting, lumbering operations throughout the State, seed gathering, exhibit made at the St. Louis Exposition, etc.

In the Adirondack forests 578,592,440 ft. B. M. of lumber were cut, and 31,516,450 shingles, and 52,659,692 laths made. In the Catskill forests 120,695,320 ft. B. M. were cut. Five hundred bu. of white-pine cones were secured during the year, from which 500 lbs. of clean seed were obtained, at an average cost of 47.5 cts. per pound.

Belgian woodlands and their management, F. H. OSMOND-SMITH (*Agr. Students' Gaz., n. ser., 12 (1905), No. 5, pp. 155–163*).—An account of the visit of the Royal English Arboricultural Society to a large number of Belgian state and private forests with notes on the forestry practices observed in different localities of Belgium.

The forestry conditions and management of Bosnia and Herzegovina, L. DIMITZ (*Vienna: Wilhelm Frick, 1905, pp. VIII+389, map 1*).—An account of the history, cultural condition, climate, vegetation, people, and development of the forests under Austrian supervision during the past 25 years of these provinces where about 5,000,000 acres are devoted to forestry.

An account of the methods pursued in the systematic management of these forests and of the results obtained is of especial interest to American foresters, since forestry conditions at the time the work was begun are more or less comparable with forestry in certain parts of the United States at the present time. A list of the numerous publications consulted by the author in the preparation of this work is appended.

Report of the conservator of forests, Natal, T. R. SIM (*Rpt. Conserv. Forests Natal, 1903–4, pp. 67, maps 2*).—An account of the forestry service of Natal and of the work done in the demarcation of forests, afforestation, establishment of nurseries, forest protection, revenues derived from state forests, condition of the game preserves, and the preparation of land for a fruit orchard.

An outline is given of an experiment underway in the use of fertilizers for black wattles, and of different quantities of seed sown broadcast in clumps and at different distances apart. An experiment was also made to see if chemicals could be drawn into wattle timber by natural suction which would render it

durable and ant proof. A copper sulphate solution was used and 4 wattle trees varying from 4 to 6.5 in. in diameter and 40 to 56 ft. high were cut off and the cut ends placed in tubs of the solution, the trees being supported in a vertical position. With 2 of the trees the bark was peeled off.

With both peeled and unpeeled trees the solution was rapidly taken up, sinking in to a depth of 0.5 to 1 in. in the stem. The experiment is believed to be too expensive to be of practical use. Nevertheless, poles from these trees have been planted and the length of time they remain sound will be noted.

The wattle industry in 1903 amounted to 12,135 tons. Neither *Acacia mollissima* nor *A. dealbata* was found a satisfactory source for paper pulp.

Forestry in Kiao-chou, Borgmann (*Ztschr. Forst u. Jagdw., 37* (*1905*), *No. 12, pp. 790–802*).—General notes on the political and forestry conditions in this German colony in China, with an account of the results obtained in planting many species of broadleaf and evergreen trees. The only species of pine that has succeeded is *Pinus thunbergii*. The gingko tree (*Gingko biloba*) also grows well. On the whole considerable progress has been made along forestry lines under rather unpromising conditions.

The effects of the great frosts on the forests of northern India, E. R. Stevens and E. A. Courthope (*Indian Forester, 31* (*1905*), *No. 8, pp. 435–440*).—Notes on the effects of the abnormal frost, during January and February of 1905, on the Dun and Saharanpur forests, with lists of the trees and shrubs most injured and of those apparently unaffected by the frosts.

Para rubber in Ceylon (*West Indian Bul., 6* (*1905*), *No. 3, pp. 302–306*).—The results are given of observations on the growth of Para rubber in the Royal Botanic Gardens of Ceylon with an account of the chemistry of Para rubber, analyses being given of the fresh leaves and stalks, decayed fallen leaves and stalks, and of the wood and branches. The data are quoted from a circular of the Royal Botanic Gardens, Ceylon.

Results of the experimental tappings of Hevea brasiliensis, W. R. Tromp de Hass (*Agr. Bul. Straits and Fed. Malay States, 4* (*1905*), *No. 8, pp. 285–292; Teysmannia, 16* (*1905*), *No. 3, pp. 182–190*).—This article gives the results of experiments carried on at the Economic Gardens at Tjikeumeuh during 1900–1904.

In one experiment when the lengths of the incisions per square meter of surface were 104, 320, and 740 cm., respectively, the corresponding yields were 158, 384, and 407 gm. of rubber. It is thus seen that in the latter instance when the length of the incision was more than doubled the increase was but 23 gm. of rubber per square meter of tapped surface.

In another experiment the wounds were opened on both the upper and lower edges and the resulting rubber yield compared with that obtained when only the lower edge was cut. Where both edges were opened the average yield in one test was 238 gm. per square meter of surface as compared with 143 gm. when only the lower edge was opened.

Notwithstanding the fact, however, that more rubber can be obtained by reopening both the upper and lower edges this increased yield does not cancel the disadvantages of the incisions becoming so broad as to interfere with proper healing. It is therefore suggested that if after the wounds have been reopened 10 times they still yield much latex, it is advisable to continue the tapping a little longer only on the lower edge of the incisions instead of working both edges.

As to the time of year when the trees should be tapped, the author states that in wet years it does not matter when the Hevea trees are tapped. In normal years the best times for tapping are generally at the beginning and end of the wet seasons.

DISEASES OF PLANTS.

Recent researches on the parasitism of fungi, H. MARSHALL WARD (*Ann. Bot., 19 (1905), No. 73, pp. 1–54; abs. in Bot. Centbl., 98 (1905), No. 16, p. 419*).—This is an address delivered by the author before the British Association for the Advancement of Science, in which he reviews the literature relating to parasitism of fungi, paying particular attention to the parasitism of cereal rusts.

The author in concluding his paper rejects the mycoplasm hypothesis of Eriksson, and states that inasmuch as uredospores can be found almost continuously the year round, and that they may develop on tufts of grass here and there during the winter and retain their germinating power for at least 2 or 3 months and perhaps longer, and, further, that specialized forms can occasionally infest races of wheat which normally prove immune, there is no necessity for explaining parasitism by any mycoplasm theory.

He has been unable to find any trace of mycoplasm, and from the present facts regards the revision of the hypothesis as necessary. He predicts that if infesting spores are sought for by means of serial sections they will ultimately be found.

A bibliography of more than 200 papers relating to parasitism of fungi is appended to the address.

Some recent observations on plant diseases, P. RIPPERT (*Fühling's Landw. Ztg., 54 (1905), Nos. 14, pp. 481–487; 15, pp. 513–516*).—A summary is given of the present status of knowledge regarding a number of diseases of economic plants, and means are suggested for their control.

Among the diseases described are the blackleg of potatoes due to *Bacillus phytophthorus*, rusts of cereals and grasses caused by different species of Puccinia, cereal smuts, blights of cereals due to *Helminthosporium gramineum* and *H. teres*, and the gummosis and canker of fruit trees. For the prevention of cereal smuts the author recommends the formalin treatment of the seed.

On endophytic adaptation shown by Erysiphe graminis under cultural conditions, E. S. SALMON (*Ann. Bot., 19 (1905), No. 75, pp. 444–446*).—In other papers (see below) the author has pointed out the fact that certain species of Erysiphe under cultural conditions are able to infest their host plants when their conidia or ascospores are placed on the cells of the internal tissues exposed by wounds, etc.

In the present paper an abstract is presented of a longer report, giving the results of experiments carried on with the conidial stage of *E. graminis*, a strict ectoparasite under normal conditions. The author shows that this mildew is not so highly specialized as an ectoparasite as to be restricted for its food supply to the cells of the epidermis, but is capable of adaptation to conditions closely resembling those obtaining in endophytism.

This suggests the possibility that under some circumstances the mycelium of species of Erysiphaceæ may penetrate into the internal tissues of their host plants exposed through wounds caused by the attacks of animals or by physical agency. It is pointed out, however, that the entry of the hyphæ might probably be prevented to a considerable extent by the drying up of the superficial layers of cells or by the healing processes which take place with great rapidity in the leaves.

Further cultural experiments with "biologic forms" of the Erysiphaceæ, E. S. SALMON (*Ann. Bot., 19 (1905), No. 73, pp. 125–148; abs. in Bot. Centbl., 98 (1905), No. 16, pp. 418, 419*).—In the present paper experiments are described

in which inoculations were made of various species and races of grass with *Erysiphe graminis*.

The leaves were injured and thereby rendered susceptible to the attacks of conidia and ascospores. The injuries were inflicted by bruising the leaves, pressing them under weights, the action of narcotics, heat, etc., and it is pointed out that injuries similar to those artificially produced in the experiments are constantly inflicted on plants in nature by animals, frost, wind, hail, etc. In the experiments with barley leaves they were rendered susceptible by the agricultural practice of rolling the crop.

As an explanation of the susceptibility of injured leaves, the author assumes that in consequence of the vitality of the leaf cells being affected the protection normally afforded by enzyms or similar substances ceases.

The results obtained in these experiments show that "susceptibility can be induced not only by various kinds of mechanical injury, but also by such interference with the normal functions of the cell as follows the application of anesthetics and heat. The conidia of the first generation produced on leaves of a strange host plant previously subjected to the action of alcohol, ether, or heat retain the power of infecting their original host, and do not acquire the power of infecting normal leaves of their temporary host."

The vegetative life of some Uredineæ, J. ERIKSSON (*Ann. Bot., 19 (1905), No. 73, pp. 55–59; abs. in Bot. Centbl., 98 (1905), No. 16, p. 415*).—The author presents in a paper read before the British Association some additional evidence to substantiate his mycoplasm theory regarding rust infection.

Report of the botanist and geologist, W. LOCHHEAD (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 43–58, figs. 2*).—A review is given of the progress in this department during the author's occupancy as professor of botany and geology, after which an account is given of some spraying experiments with grapes for the protection of the vines against grape rot and experiments for the destruction of the San José scale.

The season was unsatisfactory for spraying experiments, as there was but little disease present in any of the vineyards, and the experiments will be repeated. In the spraying experiments for the protection against the San José scale a number of mixtures were tested, but none of them proved as effective as the lime-sulphur washes in common use. A brief account is given of potato spraying in which Bordeaux mixture and Paris green were compared with a number of other combined insecticides and fungicides, and the best results were obtained where the Paris green-Bordeaux mixture was applied.

Notes are given on a number of fungus diseases which have been given some attention during the past season, and the report concludes with a discussion of the injurious action of Bordeaux mixture in apple orchards. An instance of possible injury to the foliage and fruit is cited, and experiment station and other literature is quoted to show the possibility of injury from the improper use of Bordeaux mixture, but the author concludes from his observations that it is probable that the leaf spot was caused by the scorching of the leaves by the hot sun shining through the moistened surfaces of the leaves. He does not consider it demonstrated that the injury was due to the spraying with Bordeaux mixture.

Treatment of grain for smut, C. A. ZAVITZ (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 182–185*).—The results of treating 2 varieties of oats and 2 of winter wheat with solutions of formalin, copper sulphate, potassium sulphid, etc., for the prevention of smut are described. It is shown that from the untreated seed an average of about 9 per cent of the smut occurred in the case of winter wheat and 4 per cent in the case of oats, while the crop produced from the seed which had been treated with formalin was entirely free from

smut and the percentage present in the plats the seed for which had received other treatments was greatly reduced.

A brief account is given of an experiment to test the claims that naptha powder mixed with wheat or oats will prevent the rust of those grains. The results of the investigation showed that the application of the chemical had no effect whatever in reducing the amount of rust.

Rust in oats, A. H. COCKAYNE (*New Zeal. Dept. Agr., Div. Biol. and Hort. Bul. 3, pp. 9, pls. 2*).—A general account is given of cereal rusts, after which notes are presented on the injury caused by those attacking oats, *Puccinia coronata* and *P. graminis avenæ* being of the greatest economical importance.

Numerous spraying experiments were carried out with copper sulphate, eau celeste, ammoniacal copper carbonate, Bordeaux mixture, iron chlorid, iron sulphate, and potassium bichromate. The attacks of rust are somewhat diminished by the use of Bordeaux mixture, eau celeste, and potassium bichromate, but the expense and method of treatment render it impracticable.

From the present knowledge of the subject the author states that spraying is of no practical use, and that the production of rust-proof varieties offers the most promising method of combating cereal rusts. In order to reduce the tendency to disease the author recommends care in the use of manures, particularly those containing a high amount of nitrogen, careful drainage, the removal of all weeds and wild plants which are liable to be host plants for the rusts, early sowing, and where a crop is badly infested, the burning of the straw.

Bordeaux mixture for the potato blight, C. A. ZAVITZ (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), p. 199*).—An account is given of spraying experiments with Bordeaux mixture for the control of the potato blight, in which the investigations have been carried on for a number of years. The past year 3 sprayings were given, and the average results show that there was less rot on the potatoes on which Bordeaux mixture and Paris green were used than on those where Paris green alone was applied. The 3 applications of Bordeaux mixture did not seem sufficient to prevent all the rot, and it is probable that 5 or 6 applications should be made.

The prevention of potato rot, F. PARISOT (*Jour. Agr. Prat., n. ser., 9 (1905), No. 26, pp. 821, 822*).—After describing the potato rot and its effect upon the crop, the author gives suggestions for its control.

Among the fungicides recommended he prefers the Burgundy mixture, which consists of copper sulphate 2 kg., sodium carbonate 1,500 gm., and water to make 100 liters. This should be thoroughly sprayed over the plants, using from 12 to 15 hectoliters per hectare. This fungicide is recommended on account of its great adhesiveness. When properly made a gelatinous precipitate is formed, and to get this in the best condition the mixture should be made cold. The color of the solution should be a clear blue. A greenish coloration is an indication of improper mixing.

Treatment for potato scab, C. A. ZAVITZ (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 200, 201*).—The author describes the treatment of seed potatoes with corrosive sublimate solution for the prevention of scab, and although in general the crop showed but a relatively small amount of scab, the results of the experiments indicate that the treatment will be a successful one where a scabby crop is to be expected.

The white rust of tobacco and the mosaic disease, G. DELACROIX (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), No. 10, pp. 678–680*).—In 1894 the author in conjunction with E. Prillieux described a disease of tobacco that has since been considered as identical with the mosaic disease (E. S. R., 5, p. 1019). At that time it was claimed to be of bacterial origin, but the author now believes

that it was not the true mosaic disease but was one commonly referred to by growers as white rust. It is claimed that other investigators have not distinguished between these two diseases, and hence the confusion regarding the results of experiments.

The writer believes that the white rust is of bacterial origin, while the cause of the mosaic disease is still in dispute. The malformation and atrophy of the leaves that characterize severe cases of mosaic disease are rarely met with in France, the predominating characters being a uniform mottling of the younger leaves into different shades of green. A similar coloring is noticed on plants attacked by the white rust, except the areas are not so numerous and are more definitely limited. In addition the rust spots are rarely observed on the young leaves, but usually upon the older ones.

In the true mosaic disease the discoloration spreads over the blade of the leaf until it becomes of a uniform yellowish green color, the leaf finally drying up. In the white rust the spots are limited by a brownish margin, which becomes suberized, checking further spread. At the same time the center of the spot becomes pale, more or less blanched, and dried. The organism has been isolated and studied, its principal characters being described.

The spot disease of Iwanowski (E. S. R., 6, p. 234), the spotting of tobacco leaves reported by Sturgis (E. S. R., 11, p. 755), and the mosaic disease of a number of authors are all believed to be different from the true mosaic disease and identical with the white rust. The organism is believed to be undescribed, and the name *Bacillus maculicola* is given it.

A bacterial disease of cabbages, cauliflower, etc., G. DELACROIX (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), No. 20, pp. 1356–1358*).—The author states that during the summer of 1904 numerous specimens of cabbage, cauliflower, Brussels sprouts, etc., were received which showed unusual coloration and lesions on the petioles of the leaves and the bases of the stems.

In a number of cases the disease appeared to have been arrested by the formation of a cork layer about the affected spots, and in such cases lateral buds developed but never attained marketable size. The disease seemed to be most troublesome on soils that had a high nitrogen content, and it is believed that this predisposed the plants to attack.

From the diseased material the author isolated an organism, to which he has given the name *Bacillus brassicævorus* n. sp. Cultures were made of the organism, and inoculation experiments showed that it was possible to produce the disease in a number of vegetables related to the cabbage. Infection experiments with filtered juice of the plants made at the same time produced lesions, but did not develop the typical form of the disease.

This organism is believed to be different from that causing black rot of cruciferous plants or the bacterial disease recently described in Canada, *Bacillus oleraceæ* (E. S. R., 16, p. 480).

A fungus of the roots of the grapevine, L. MANGIN and P. VIALA (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), No. 22, pp. 1477–1479*).—The authors describe *Stearophora radicicola*, a fungus which was observed by them during their studies on phthiriosis of the vine.

This fungus seems to attack the roots of dead or dying vines where they have been attacked by phylloxera, nematodes, etc., and the fungus quickly completes the destruction. The presence of the fungus in living tissues seemed to indicate that it also played a parasitic rôle, but the authors are not yet prepared to definitely determine this question. The fungus is technically described.

Combined treatment for the prevention of downy and powdery mildew, J. Mossé (*Rev. Vit., 23 (1905), No. 600, pp. 658–662*).—For the prevention of

these diseases by the use of a single fungicide the author recommends an alkaline polysulphid added to a verdigris solution.

Mildew and gray rot (*Rev. Vit., 24 (1905), No. 603, pp. 15, 16, pl. 1, fig. 1*).—A description is given of the attack of *Peronospora viticola* on the leaves and fruit of the grape. Upon the leaves it is called downy mildew and upon the fruit it is designated usually as gray rot. Spraying with fungicides containing some form of sulphur is recommended for the prevention of the disease.

Treatment of black rot, L. BERGEYRE (*Prog. Agr. et Vit. (Ed. l'Est), 26 (1905), No. 23, pp. 682–684*).—The efficiency of copper fungicides when properly applied is shown, and the author comments on the effect of humidity and a high temperature on the rapid spread of the disease.

Usually 4 sprayings will be found sufficient, the first of which should be applied as the buds are swelling, the second 20 to 30 days later, the third at the beginning of flowering, and the fourth after an interval of 20 to 30 days. The first and third of these applications are said to be the most important, and the necessity for the second and fourth will depend on the humidity of the atmosphere.

Black rot in Marmande, A. GUY (*Prog. Agr. et Vit. (Ed. l'Est), 26 (1905), No. 26, pp. 772–776*).—An account is given of the first and second periods of black rot invasion during 1905.

The first appearance of the fungus was noted the latter part of April, a few spots showing here and there on the leaves, and the next invasion was observed between May 27 and 29. The atmospheric conditions during this period are described. Where sprayings were made before May 5 the treatment was efficient in reducing the severity of subsequent attacks. This date corresponds to a period of low temperature preceding a rather heavy rain. Applications of fungicides after the rain when the temperature was rising rapidly were much less efficient.

A remedy for the prevention of coulure, A. BERNET (*Prog. Agr. et Vit. (Ed. l'Est), 26 (1905), No. 35, p. 252*).—For the prevention of this disease, which is probably of physiological origin, the author suggests the spraying of the vines some days before flowering with a solution containing 3 kg. of iron sulphate to a hectoliter of water. This solution checks to some extent the growth, which becomes vigorous again after the advent of warm weather, and the new growth shows no trace either of chlorosis or of coulure.

Bud rot of cocoanut palm (*Agr. News [Barbados], 4 (1905), No. 90, p. 299*).—A description of this disease was previously given by F. S. Earle (E. S. R., 14, p. 881), and since that time it has been reported as occurring in Central America and throughout most of the countries surrounding the Caribbean Sea. In some places it has become epidemic and has destroyed many plants.

Experiments carried on at the Public Gardens of Jamaica seem to indicate that spraying with Bordeaux mixture is beneficial when the applications are made before the disease has progressed too far. This beneficial use of Bordeaux mixture indicates that the disease is not as deeply seated as has been previously believed. On account of the seriousness of this disease, energetic and concerted action is needed to keep it in check.

A fungus on Para rubber leaves, H. N. RIDLEY (*Agr. Bul. Straits and Fed. Malay States, 4 (1905), No. 7, pp. 271, 272*).—A brief account is given of attacks of a species of Cercospora on the leaves of Para rubber plants.

The fungus causes the occurrence of pale blotches upon the leaves and when placed under conditions favorable to the growth of the parasite frequently destroys the leaves outright. Except in the case of the seedlings, the disease does not seem to do much harm, but it checks the growth of young plants and

if neglected would probably prove serious in the nurseries. The treatment o. the plants with Bordeaux mixture and the removal of the dead leaves are recommended.

The effect of different soils on the development of the carnation rust, J. L. SHELDON (*Bot. Gaz., 40 (1905), No. 3, pp. 225–229*).—The author reports the results of investigations to determine the effect of different kinds of soil on the development of the carnation rust. Previous inoculations of asparagus, onion, Dianthus, and Gypsophila with asparagus and carnation rusts seemed to indicate that the conditions which were favorable for the development of the host were also favorable for the development of the rust.

In the experiments reported upon a considerable number of inoculations were made on asparagus and Dianthus, in which plants of different ages were used and kept in the greenhouse under control from other infection. The results show that the plants that were making a vigorous growth were more susceptible to artificial infection than those that were making no apparent growth. Some carnations which were inoculated 5 or 6 times at intervals of 20 days did not show any trace of disease. These plants had grown very slowly, were slender, and produced only 1 or 2 small blossoms.

The varying susceptibility of varieties of carnations to rust is commented upon, and the author notes the difference in the period of incubation of the rust on the green and glaucous-leaved species which were inoculated at the same time.

A lack of susceptibility to inoculation is reported for seedling onions inoculated with the asparagus rust. These inoculations were made as soon as the seedlings appeared above ground and were repeated at frequent intervals until the seedlings were two months old. After this time almost every inoculation was successful.

The author attributes the failure on the part of other investigators to a lack of susceptibility of the host at the time the inoculation was made, and not to a failure of the spores to germinate or to the way the inoculation was made.

As a means of testing the effect of different soils on the period of incubation of the rust, a green-leaved pink which was known to be susceptible to carnation rust was selected. Rooted cuttings were planted in 5 different kinds of soil, ranging from almost pure sand to soils containing little sand, being made up mainly of organic matter and clay. The plants were arranged in series, and of 170 plants inoculated only 3 failed to show rust pustules in 16 to 21 days, the majority showing in 17 to 19 days.

The author summarizes the results of his investigation, the details of which are to be published later, stating that the intensity of color in the plants was directly proportional to the amount of clay in the different soils. The growth of the host was directly proportional to the amount of organic matter, nitrogen, and silt in the different soils. The period of incubation of the carnation rust, while not uniform in every instance, was in general inversely proportional to the amount of organic matter, nitrogen, and silt in the different soils, and to the growth of the host; it was directly proportional to the amount of gravel and sand in the different soils. Those soils that were found favorable for the development of the host plant also favored the development of the rust, namely, those containing the most organic matter combined with silt and clay and a small amount of sand—soils which had a high-water retentivity and which were rich in nitrogen.

A new parasite of oxalis, L. TRABUT (*Bul. Agr. Algérie et Tunisie, 11 (1905), No. 8, pp. 168, 169*).—According to the author a number of species of ornamental oxalis were observed parasitized by the broom rape (*Phelipæa*

muteli). In addition to occurring on oxalis, this same plant occurs as a parasite in Algeria upon the tomato, often causing considerable loss.

Investigations on the comparative adherence of fungicides, E. CHUARD and F. PORCHET (*Compt. Rend. Acad. Sci.* [*Paris*], *140* (*1905*), *No. 20, pp. 1354–1356*).—On account of the ease with which it is prepared, it is said that in many regions a 1 per cent solution of neutral acetate of copper is extensively substituted for the ordinary fungicides, such as Bordeaux mixture, etc. The acetate of copper is easily soluble in water, does not appear unsightly on the foliage, and its efficiency is believed to be equal to fungicides containing lime or soda.

In order to test the subject the authors made a study of the relative adhesive properties of this mixture, comparing it with Bordeaux mixture and Burgundy mixture. Eight applications were made to vines under identical conditions and on the same dates, and the amount of copper adhering to the foliage was determined. The relative amounts of copper adhering to the foliage are shown. When the strength of the different solutions is compared, the amount of copper adhering to the leaves sprayed with the neutral copper acetate solution was the greatest.

A study of sulphur fungicides, J. B. MARTIN (*Prog. Agr. et Vit.* (*Ed. l'Est*), *26* (*1905*), *No. 25, pp. 736–742*).—On account of the desirability of a combined fungicide for use against both the downy and powdery mildew of the grape, many investigators have recommended the addition of sulphur in some of its forms to Bordeaux mixture and thus treat for both diseases at one spraying. The author cautions against this practice, and cites a number of investigations which seem to throw doubt on the efficiency of such treatments. In general he claims that separate treatments will give the best results against both diseases.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Report of the entomologist, H. TRYON (*Queensland Dept. Agr. Rpt. 1904–5, pp. 125–134*).—As usual, in the author's reports, notes are given on a large number of insect and fungus pests which have attracted attention during the year. Among the more important species mention may be made of *Tephritis tryoni*, bollworm, sweet-potato weevil, cattle tick, and horse botfly. Brief notes are also given on apiculture, insectivorous birds, and fungus diseases.

Insects injurious to corn, A. R. KOHLER (*Iowa Agr.*, *6* (*1905*), *No. 3, pp. 82–86*).—The numerous insects which attack this crop are grouped according as they affect the seed after planting, the roots, and the stalk and leaves. In this discussion particular attention is given to seed-corn maggot, wireworms, northern corn-root worm, corn-root louse, bill bugs, chinch bug, army worm, and bollworm.

Report on miscellaneous cotton insects in Texas, E. D. SANDERSON (*U. S. Dept. Agr., Bur. Ent. Bul. 57, pp. 63, pl. 1, figs. 33*).—The present account of the less important insects which attack cotton in Texas is supplementary to investigations conducted by the Bureau of Entomology on the cotton-boll weevil and bollworm.

The prevalence of these species is briefly described, and the various insects discussed are arranged largely according to the nature of their attack or the part of the plant affected. Thus the classification includes leaf-eating caterpillars, insects affecting the stalks, and insects affecting the fruit. Notes are given on the habits, life history, and means of combating a large number of species, including cutworms, May beetles, locusts, beet army worms, stalk borers, snowy tree cricket, plant bugs, and sharpshooters.

Coffee-leaf miner and other coffee pests, M. T. Cook and W. T. Horne (*Estac. Cent. Agron. Cuba Bul. 3, pp. 22, pls. 5, fig. 1*).—A brief historical statement is made regarding coffee cultivation in Cuba.

At present Cuba does not produce enough coffee for home consumption. In order to increase the acreage of coffee it is desirable to have information available for coffee growers on the most important insects of this plant. The coffee-leaf miner causes a loss of about 20 per cent of the coffee crops in Porto Rico, Brazil, and Cuba. The injuries produced by the pest consist in large irregular red spots on the leaves. The insect was reared under artificial conditions in the laboratory for the purpose of studying its habits and testing remedies for its control. The larva of the coffee-leaf miner appears to feed upon the 2 upper layers of mesophyll cells beneath the epidermis.

A number of parasites of the pest are known. One artificial treatment against the coffee-leaf miner consists in picking and destroying the leaves. This is a tedious method, however, and injures the plants. Since the larvæ are inside of the leaves it is impossible to reach them immediately by insecticides. The pupæ, however, are on the outside of the leaves, and may be destroyed by the use of kerosene emulsion containing one part each of kerosene and soap per 8 parts water. Good results are obtained from the use of this remedy both in the laboratory and field.

The insect produces numerous broods and this necessitates frequent spraying. It is recommended that the application of kerosene emulsion be made regularly twice a week, beginning 6 or 8 weeks before the close of the rainy season and continuing until the commencement of the dry season. Biological and economic notes are also given on the hemisphere scale and other scale insects, mealy bugs, boring insects, case borer, nematode worms, leaf spot, *Hemileia vastatrix*, *Stilbum flavidum*, etc.

Treatment for the potato beetle, C. A. Zavitz (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 199, 200*).—For the past 10 years a comparative experiment has been in progress for the purpose of determining the relative value of potato-bug finish, Paris green mixed with plaster and water, and bug death dry and in water.

The Paris green has been used at the rate of 1 lb. in 96 gal. of water per acre or 1 lb. in 38 lbs. of plaster, while potato-bug finish was used at the rate of 20 lbs. per acre, and bug death at the rate of 32 lbs. The yield of potatoes sprayed with bug death appeared to be somewhat higher than was obtained when other insecticides were used. The cost of Paris green application per acre, however, was 60 cts., while that of bug death was $6.72.

Apple maggot, F. W. Card and M. A. Blake (*Rhode Island Sta. Rpt. 1905, pp. 197, 198*).—A number of apple maggot pupæ were placed in the soil in frames and the soil was cultivated from 7 to 10 days to a depth of 2 to 3 in. Other pupæ were placed in similar frames in which the soil was not cultivated. For some reason none of the pupæ emerged.

Winter apples from orchards in which hogs were allowed to run were comparatively free from maggots, and the results indicate that pasturing the orchard will destroy enough of the maggots for practical purposes. Fall pippins and winter apples were almost wholly free from injury, while in a tilled orchard early varieties of apples were badly injured.

Spraying for San José scale, H. E. Hodgkiss, F. A. Sirrine, and E. L. Baker (*New York State Sta. Bul. 273, pp. 473–500, pls. 4*).—In this series of experiments 5 orchards were selected in Geneva and Northville containing 596 apple, plum, and peach trees.

Applications with lime-sulphur-salt were made between November 11 and December 1. For purposes of comparison various formulas were used including

a boiled lime-sulphur-salt wash, self-boiled lime-sulphur-salt wash, lime-sulphur wash, lime-sulphur-caustic-soda boiled and self-boiled. The effect on peach-leaf curl was quite striking, only 1½ per cent of the leaves being affected on the treated trees, while on the checks 85 per cent showed leaf curl. Some of the trees were quite severely injured by self-boiled lime-sulphur-salt wash, but this injury was more than offset by the increased growth of the trees during summer.

Lime-sulphur-caustic-soda wash gave quite satisfactory results. In one orchard about 10 per cent of the peach buds were injured by the treatment. The insecticidal value of all lime-sulphur preparations was uniformly good and the injuries caused to trees were in all cases offset by increased vigor and fruitfulness. It is concluded that spraying in the fall with lime-sulphur washes is not attended with any danger.

Various kerosene-lime mixtures were used containing kerosene in quantities varying from 10 to 40 per cent, and lime in quantities varying from 20 to 80 lbs. in 50 gal. of water. Considerable difference was noticed in the different kinds of limoid and hydrate of lime which were used. The kerosene-limoid mixture containing 10, 20, or 40 per cent of oil injured trees in all cases to some extent, and even the trees which received the highest percentage of oil were well covered with young scales when examined during the next season. The kerosene-limoid mixture appeared to have no effect upon peach-leaf curl.

None of the mixtures of kerosene and limoid appeared to be uniformly effective upon the scale. This was attributed to the instability of the emulsion. On account of the variable results this insecticide appears unsatisfactory, but further experiments will be made. The technical methods for determining the amount and condition of the kerosene in the mixture are described. Applications with scalecide were made on April 26 to apple, peach, pear, and quince trees on which the buds were just swelling. The amount of oil varied from 3 to 15 per cent.

In another test an application was made on June 20 in which the amount of oil varied from 3 to 7½ per cent. Trees sprayed in the dormant season appeared to be free from living scales when examined during July and August. When 15 per cent of oil was used the trees were quite severely checked, but applications containing from 5 to 10 per cent of oil appeared to destroy from 80 to 95 per cent of the scales.

Testing spray mixtures for San José scale, F. H. Hall et al. (*New York State Sta. Bul. 273, popular ed., pp. 7, fig. 1*).—A popular summary of the above bulletin.

Some important scale insects, H. T. Fernald (*Agr. of Mass., 1903, pp. 425–437, pl. 1, figs. 5*).—A brief descriptive and economic account is given of San José scale, oyster-shell bark-louse, scurfy scale, and certain species of Lecanium.

The biology of Ceratitis capitata, A. Hempel (*Bol. Agr. [São Paulo], 6. ser., 1905, No. 8, pp. 352–354*).—The life history and economic importance of this pest are briefly discussed with notes on means of combating it.

An insect of the family Poduridæ on grapevines, H. Faes (*Chron. Agr. Vaud, 18 (1905), No. 15, p. 352*).—*Smynthurus luteus* was found in large numbers attacking the leaves of grapevines in the vicinity of Valais. Brief notes are given on the anatomy of the insect. It was found a comparatively easy matter to eradicate this pest by spraying with a mixture of soap and tobacco decoction.

Stick or leaf insects, W. W. Froggatt (*Agr. Gaz. N. S. Wales, 16 (1905), No. 6, pp. 515–520, pl. 1, figs. 3*).—Some of the more interesting points connected with the life history of these insects are discussed by the author.

Particular attention is given to *Podacanthus wilkinsoni*, which attacks all species of eucalyptus. This species inhabits a wide strip of forest land about

50 miles in length and causes such serious depredations that it has acquired the name of ringbarker. This name is due to the fact that trees are so badly injured as to be suspected of dying of ringbarking. The habits of *Extatosoma tiaratum* are also discussed.

The Gryllidæ and wingless Locustidæ, W. W. FROGGATT (*Agr. Gaz. N. S. Wales, 16 (1905), No. 5, pp. 477–481, pl. 1*).—The biology and habits of these 2 families of insects are briefly outlined and special notes are given on Australian cricket, mole cricket, and a number of locusts of economic importance.

The Black Hills beetle, with further notes on its distribution, life history, and methods of control, A. D. HOPKINS (*U. S. Dept. Agr., Bur. Ent. Bul. 56, pp. 24, pls. 2, figs. 6*).—Notes are given on the literature relating to *Dendroctonus ponderosæ*. This pest was studied in Pikes Peak forest reserve and was found not to occur so abundantly as had been supposed. It is, however, the most destructive pest of pine timber in that region.

The insect is described and notes are given on the galleries produced by it in infested trees and on its life history. The beetle apparently withstands great extremes of drought and cold. Trees struck by lightning or injured by storms or fire are most frequently attacked. The natural enemies of this pest appear to have little influence in controlling it. The only practical method suggested for the control of this pest is to cut all infested trees between the middle of October and the 1st of May.

Gall gnats injurious to osiers and willows, R. S. MACDOUGALL (*Jour. Bd. Agr. [London], 12 (1905), No. 8, pp. 499–503, figs. 5*).—The feeding habits of the larvæ of this group of willow pests vary considerably, but all known species are found in characteristic galls on twigs, flower buds, or leaves.

Detailed descriptive notes are given on *Cecidomyia saliciperda, C. salicis, C. rosaria, C. terminalis, C. heterobia,* and *C. marginem-torquens.* In general the only effective remedy consists in removing and burning the galls before the occupants escape.

A treatise on the acarina, or mites, N. BANKS (*Proc. U. S. Nat. Mus., 28 (1905), pp. 1–114, figs. 201*).—The internal and external anatomy of mites is discussed with special reference to those features which may be used in a scientific system of classification. Tables are presented to assist in the identification of the superfamilies, families, genera, and species of this group of animals. The more important species are discussed in some detail with brief reference to their economic significance.

The mosquito blight of tea, H. H. MANN (*Indian Tea Assoc. [Pamphlet] 1, 1905, pp. 19, pl. 1*).—It has been shown that on isolated fields of tea this pest may be practically exterminated in one season by pruning and spraying with kerosene emulsion. The cost of this treatment is not excessive.

A number of experiments were carried out to test the value of hand picking the insects through the agency of boys. In this work it was found necessary to assign one boy to each 5 acres of tea. The kerosene emulsion used in the author's experiments was made up of 1 to 2 lbs. of soft soap and 2 gals. of low-grade kerosene per 50 gal. of water, and was applied at the rate of 150 gal. per acre.

Preliminary experiments in dipping nursery stock, F. W. FAUROT (*Missouri Fruit Sta. Bul. 14, pp. 7*).—In the spring of 1904 some dipping experiments were undertaken with nursery stock.

Two lots of trees were divided into 3 bunches each and one of these lots was treated with lime-sulphur-salt in full strength, one-half strength, and one-fourth strength, while the other lot was dipped in formalin for one-half hour, 1 hour, and 1½ hours, respectively. The formalin solution was made at the rate of 1 pt. to 30 gal. of water, and the full strength lime-sulphur-salt wash, according to

the formula 15–15–15–50. Of the 6 bunches of trees in the two lots in the order just mentioned, the following numbers lived after setting out—22, 22, and 24 in the lime-sulphur-salt test; 24, 25, and 23 in the formalin test, as compared with 21, 23, and 25, respectively, of untreated trees.

During the next spring another test was made in which 25 plants each of apple, peach, and blackberry were dipped in full strength lime-sulphur-salt solution and 25 each of the same varieties fumigated with hydrocyanic-acid gas (1 oz. to 100 cu. ft.) for 45 minutes. Of this nursery stock, 25 apple trees, 21 peach trees, and 24 blackberry bushes treated with lime-sulphur-salt lived, while of those fumigated 24 apple trees, 25 peach trees, and none of the blackberries lived as compared with 25, 24, and 25, respectively, of untreated specimens. The lime-sulphur-salt is considered as possessing several advantages over other kinds of treatment.

Michigan laws for the protection of orchards and vineyards (*Lansing: Wynkoop, Hallenbeck, Crawford Co., 1905, pp. 11*).—A copy is given of the law recently passed in Michigan to prevent importation and spread of dangerous insects and fungus pests. The law provides for the appointment of an inspector of orchards and deputies, regulates the matter of nursery licenses within the State, and prescribes penalties for the violation of the law and its regulations.

Spraying mixtures and machinery. When and how to spray, F. L. Stevens and R. S. Woglum (*North Carolina Sta. Bul. 193, pp. 33, figs. 8; Sup., folio*).—The common insect and fungus diseases attacking fruits, garden vegetables, nursery stock, and field crops are mentioned with brief suggestions regarding methods of treating them. Notes are also given on the preparation of insecticides and fungicides, together with directions for the use of spraying apparatus and statements of the benefits obtained from spraying.

Fumigation with hydrocyanic-acid gas (*Jour. Bd. Agr. [London], 12 (1905), No. 8, pp. 496–498*).—The value of this remedy, as determined by experiments in various countries, is briefly outlined and practical notes are given regarding the strength of the gas to be used, the time of exposure, and other matters connected with successful fumigation.

Paris green, R. Harcourt (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 66–68*).—A study was made of the chemical composition of Paris green, and results of the analysis of several samples are presented.

From this chemical work it appears that the soluble arsenious acid in ordinary Paris green in Ontario market ranges from 2.11 to 4.35 per cent. The samples are not quite chemically pure, and small amounts of sand and sodium sulphate appear to be present in all cases. On the whole, however, the quality of Paris green in Ontario appears to be satisfactory. Between 100 and 120 tons are used annually in water and dry and also combined with Bordeaux mixture.

Alimentary canal of the mosquito, M. T. Thompson (*Proc. Boston Soc. Nat. Hist., 32, No. 6, pp. 145–202, pls. 6*).—The species studied in the preparation of this article were *Culex stimulans*, *C. pipiens*, a third unidentified species of this genus, and *Anopheles punctipennis*.

The anterior portion of the alimentary tract of mosquitoes contains a pharynx and antlia, both of which are pumping organs and are concerned in the removal of blood from the hosts upon which mosquitoes feed. The alimentary canal as a whole is discussed and detailed accounts are presented of the distinguishing features which appear in different parts of the organ.

Studies on mosquitoes of the genera culex and anopheles, B. Galli-Valerio and Jeanne Rochaz-De Jongh (*Atti. Soc. Studi Malaria, 6 (1905), pp. 1–25*).—The occurrence and behavior of mosquitoes under various temperature conditions are briefly stated in a tabular form.

Experiments were carried on to determine the agency of insects and other animals in destroying mosquito eggs, larvæ, and nymphs. Among the more important species in this work mention is made of *Notonecta glauca*, *Nepa cinerea*, *Naucoris cimicoides*, *Cyprinus prasinus*, and *Cobytis barbatula*. The possibility of infecting mosquito larva with various bacteria and fungi was also tested. It was found that *Aspergillus niger* and *A. glaucus* readily infect mosquito larvæ to such a serious degree that they are unable to complete their development.

The logical basis of the sanitary policy of mosquito reduction, R. Ross (*Science, n. ser., 22 (1905), No. 570, pp. 689–699, figs. 3*).—The author maintains that the agency of mosquitoes in transmitting malaria and filariasis may be considered as demonstrated. The importance of eradicating mosquitoes from infested districts is, therefore, considerably greater than would be the case if mosquitoes were considered merely as a nuisance themselves.

An attempt was made to put upon a mathematical basis the problem of mosquito extermination within areas of limited and large size. It is believed that, after extermination plans have been put in operation, the numbers of mosquitoes will be reduced not only within the area of operation but to a considerable distance outside of this area, at least equal to the usual distance of migration of the mosquitoes. This is due merely to the fact that mosquitoes are moving from place to place and tend to migrate into the areas in which extermination methods are in operation. The larger the area taken under such operations, the less noticeable will be the effect of migration of mosquitoes from outside sources.

The cattle tick, A. Löfgren (*Bol. Agr.* [*São Paulo*], *6. ser., 1905, No. 7, pp. 312–315*).—The importance of this tick as the agent in the transmission of Texas fever is briefly discussed. Animals may be rendered immune against the disease, but the systematic destruction of the tick is considered to be the best remedy.

The cattle tick in Washington and Benton counties, W. G. Vincenheller (*Arkansas Sta. Bul. 90, pp. 131–141*).—Federal quarantine has been enforced against the whole State of Arkansas although some of the northern counties have been free from ticks. On account of this fact a State quarantine law was enacted in 1899 for the purpose of preventing the infestation of these counties. This law has failed in its intent, however, for the reason that no provision was made for its enforcement and farmers did not realize the necessity of preventing the infestation of their farms with cattle ticks.

During the last few years the infestation of the previously tick-free counties has taken place quite rapidly as a result of the annual migration of berry pickers from farther south, some of whom take cattle along with them. It is believed that this reinfestation could have been prevented easily if a more active interest had been taken by the farmers concerned. Attention is called to the injurious effects of ticks upon animal industry, and a copy is given of the resolutions regarding the cattle tick adopted at the recent meeting of the association of the commissioners of agriculture of the southern States. Brief directions are given for dipping, burning pastures, and rotation in order to exterminate the ticks.

Bee keeping: Its pleasures and profits, J. B. Paige (*Agr. of Mass., 1903, pp. 399–411, pl. 1, figs. 2*).—The economic aspect of bee keeping is briefly discussed with particular reference to statistics obtained largely from the last census. The cost and profits of bee keeping in Massachusetts are considered in some detail, and directions are given regarding various practical matters connected with this subject.

Fourth annual report of the Illinois State Bee Keepers' Association (*Ann. Rpt. Ill. Bee Keepers' Assoc., 4 (1904), pp. 192, figs. 27*).—A list is given of the members of the association, together with copies of the constitution and by-laws of the association and laws relating to the protection of bees against foul brood.

The report is chiefly occupied with an account of the fourteenth annual session of the State bee keepers' association and the fourteenth convention of the Chicago-Northwestern bee keepers' association. One of the most important subjects bef re the meetings was that of foul brood, discussed by N. E. France (pp. 17–28 and 40–43), H. F. Moore (pp. 38, 39), and J. Q. Smith (pp. 78–80). These papers were discussed by various members of the associations.

The State inspector of Illinois does not destroy swarms of bees infected with foul brood as long as there is a fertile queen and bees enough to form a nucleus which can be built up by the addition of brood combs from strong colonies. Various other matters, such as wintering of bees, the use of baby nuclei, mating queens, and the manufacture of brick honey are discussed.

The rearing of queen bees, E. F. PHILLIPS (*U. S. Dept. Agr., Bur. Ent. Bul. 55, pp. 32, figs. 17*).—In order to obtain the best results in apiculture it is necessary to requeen the swarms every 1 to 2 years, otherwise the queen soon ceases t› lay a sufficient number of eggs to maintain a vigorous colony.

Under natural conditions queens are produced by feeding the larvæ on royal jelly. The occasions for queen producing are swarming, supersedure of the queen, and a queenless condition. Various methods have been devised for artificial queen rearing. Artificial starting cells are used for the reason that these may be better controlled and are more satisfactory than natural queen cells as found in the comb. An artificial wax base may be used or a wooden base lined with wax. Before being used for the first time these cells should be daubed with royal jelly on the inside. The larvæ should be transferred to the artificial cells within 1 to 3 days after hatching. Not all of these artificial cells are accepted by bees, but as many as is the case when natural cells are used.

Italian bees do not accept artificial queen raising as readily as Cyprians or Carniolans. In order to induce the bees to feed larvæ in artificial queen cells it may be desirable to use swarm boxes. About the day before the queen was to emerge the cell should be placed in an individual nursery cage so as to prevent the different queens from attacking one another. Detailed directions are given regarding all these matters as well as regarding the testing of queens, selection of drones, and other related subjects.

The enemies of bees, A. GALE (*Agr. Gaz. N. S. Wales, 16 (1905), No. 5, pp. 489–492, figs. 2*).—Directions are given regarding the methods of preventing the entrance of bee enemies into the hive. The enemies mentioned in this connection include spiders, tarantulas, bee louse, ants, bee moth, etc.

Treatise on the silkworm and mulberry, E. MAILLOT and F. LAMBERT (*Traité sur le ver à soie du murier et sur le murier. Montpellier: Coulet & Sons, 1906, pp. IX+622, pls. 3, figs. 169*).—The present volume is an elaborate treatise on the rearing of silkworms and the culture of mulberries.

The subjects discussed include the economic importance of sericulture, silkworm eggs, methods of preserving them, artificial hatching experiments, anatomy of silkworms, their diseases, the various races of silkworms, and other related insects which produce silk, as well as miscellaneous subjects related to the general topic. Especial attention is given to a discussion of mulberry culture (pp. 405–584).

A new flagellate parasite of the silkworm, C. LEVADITI (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 16, pp. 631–634, figs. 11*).—During a microscopic study of a number of silk moths the author discovered *Herpetomonas bombycis*, which is described as a new species, with brief notes on its life history.

FOODS—HUMAN NUTRITION.

Studies on the influence of cooking upon the nutritive value of meats at the University of Illinois, 1903–4, H. S. GRINDLEY and A. D. EMMETT (*U. S. Dept. Agr., Office Expt. Stas. Bul. 162, pp. 230*).—This bulletin reports experiments to determine the loss of nutrients which results when meat is cooked under different conditions in water, by pan broiling, by roasting, sautéing, frying, broiling, and pot roasting, as well as studies of the influence of the different methods of cooking upon flavor and palatability, and upon the nature of the substances which bones yield when cooked in hot water as in soup making, the work as a whole being a continuation of studies previously reported (E. S. R., 15, p. 988).

From the results obtained it appeared that "meats of different kinds and cuts may be analyzed directly and with accuracy—that is, without being first previously air dried. The soluble matter in meats may be completely removed by extraction with cold water and the preparation and analysis of such cold-water extracts is of great importance in studies of the true value of flesh foods. The total proportion of raw meat which is soluble in cold water is considerable, the average results showing that the cold-water extract contains about 2.3 per cent proteid, 1 per cent nitrogenous extractives, 1.6 per cent nonnitrogenous extractives, 0.7 per cent nitrogen, and 0.8 per cent ash. None of the fat present in the meat is dissolved by cold water. . . .

"Meats cooked by boiling are less soluble in cold water than are raw meats. . . .

"The different methods commonly followed in cooking meat in hot water vary somewhat as to time and temperature of cooking, but the resulting cooked meats are quite similar as regards composition and also as regards the proportion of their constituents which are soluble in cold water.

"Meats cooked by dry heat, as in roasting, broiling, sautéing, and frying, are on an average 2.4 times more soluble in water than boiled meats, but are only a little more than half as soluble as raw meats. . . .

"The more pronounced flavor of meats cooked by dry heat as compared with those cooked in hot water is without doubt due to the larger proportion of soluble constituents which the former contains. As regards the losses in weight when meat is cooked in hot water, the average values show that it is equal to from 10 to 50 per cent of the total weight of the fresh meat used, the average being about 34 per cent. . . .

"The fatter kinds and cuts of meat lose less water, proteid, and mineral matters, but more fat than leaner kinds of meat. The proportion of nutrients extracted in the broth is directly proportional to the length of time and the temperature of the cooking period. Different cuts of some kinds of meat behave differently as regards the nature and amount of the losses they sustain when cooked in hot water. On an average, the larger the piece the smaller the percentage losses. When meat is cooked in water at 80 to 85° C., placing the meat in hot or cold water at the start has little effect on the amount of material recovered in the broth. Beef used in the preparation of beef tea or broth has lost comparatively little of its total nutritive material, though most of the constituents which give flavor have been removed.

"As regards the composition of complete or unfiltered meat broths, the average results vary, the total solid matter containing from 1 to 10 per cent of the total quantity of meat used.

"The clear, filtered broths contained less of the important food elements, i. e., proteids and fat, than complete or unfiltered broths, but practically the same

amounts of the different extractive bodies and ash. In other words, they have less food value but fully as much flavor as the unfiltered broths, provided the fat is removed in both cases. Meat fat possesses more or less distinctive flavor, and if present modifies the flavor of the broth. Both filtered and unfiltered broths have a low food value as compared with the meats from which they are made, or as compared with meats cooked by dry heat or in hot water. This is obvious when it is remembered that broth or soup is made up largely of water.

"The small amount of nutritive material in broth or soup is chiefly in the form of organic extractives. The richness of the broth increases as the size of the pieces of meat used in making it decreases. An increase in the time of cooking also increases the amount of nutrients found in the broth. The broth is very little richer when made from bones as well as meat, the chief nutrients thus added being fat and soluble proteid. . . .

"The nutritive matter other than fat obtained [when bones are boiled as in soup making] from the small, spongy rib bones is greater than that from the larger and more compact shank bones. The shank bones, however, are generally preferred for soup making, possibly because of a certain flavor imparted by the marrow, which is so abundant. Aside from the fat content, the amount of nutrients in bones is small, and it is evident, therefore, that the bones contribute very little to the value of the broth.

"In general the various methods of cooking materially modify the appearance, texture, and flavor of meat and hence its palatability, but have little effect on total nutritive value. Whether it be cooked in hot water, as in boiling or stewing, or by dry heat, as in roasting, broiling, sautéing, or frying, meat of all kinds has a high food value when judged by the kind and amount of nutritive ingredients which are present."

The chemistry of flesh. III, A study of the phosphorus content of flesh, A. D. EMMETT and H. S. GRINDLEY (*Jour. Amer. Chem. Soc., 28 (1906), No. 1, pp. 25–63*).—Continuing investigations of the chemistry of meat (E. S. R., 16, p. 488), the results of an extended series of studies on phosphorus constituents are reported.

The Hart-Andrews method of separating and determining the inorganic phosphorus, the authors conclude, gives satisfactory results in aqueous extracts of flesh after the coagulable proteids have been removed. A difference in the phosphorus content of the flesh of beef and veal was noted. In the case of beef 75 per cent of the total phosphorus was soluble in cold water, one-fourth of this being soluble organic phosphorus.

With veal 64 per cent of the total phosphorus was soluble in cold water, one-sixth of this being soluble organic phosphorus. The ratio of soluble organic to soluble inorganic phosphorus in beef was 3:5 and in veal 3:9. Phosphorus formed 23.4 per cent of the ash in beef and 20.2 per cent of the ash in veal, soluble phosphorus constituting 17.8 and 12.8 per cent, respectively, of the ash in the 2 sorts.

"The percentage of fat in the different cuts of veal has little influence upon the total phosphorus content. The cuts of veal which are nearest the bony structure apparently contain more insoluble phosphorus than the other cuts. The different methods of cooking flesh give products which differ decidedly as to the quantities and the nature of the phosphorus contents. The water-soluble organic phosphorus of the aqueous extracts of flesh is not in combination with the coagulated proteid, with the albumoses or with the peptones. The soluble organic phosphorus compounds in flesh are quite stable even in the presence of considerable excess of nitric acid."

Artificial digestion experiments, E. GUDEMAN (*Jour. Amer. Chem. Soc., 27 (1905), No. 11, pp. 1436–1442*).—From artificial digestion experiments with

egg albumen digested with pepsin and pancreatin in which the effect of a number of preservatives was studied, including salicylic, benzoic, and boric acids and salts; sulphurous acid; saccharin; sugar; vinegar; ethyl and methyl alcohol; salt; formaldehyde; smoke; condensed smoke; creosote; and phosphoric, hydrochloric, and nitric acids, the following conclusions were drawn:

"In an acid medium, the only preservatives or condiments used in these tests which retarded peptic or pancreatic digestion, when in proportion of 1:400 or less, were salicylic acid, formaldehyde, smoke, condensed smoke, and creosote. Of these, salicylic acid does not retard the digestion when present in proportion of 1:1000.

"(a) In a neutral medium acid, preservatives and acid condiments increase the factor of digestibility, due to a change of the neutral medium to an acid one, and digestion proceeds normally as in the acid medium; (b) alkaline preservatives change the character of the medium and the results are abnormal, the action of the ferment being retarded.

"In an alkaline medium, preservatives and condiments react abnormally, depending on the degree of alkalinity, the action of the ferments being retarded."

Similar tests were made with a number of mineral, animal, vegetable, and synthetic colors. According to the results reported of the colors used "only ultramarine, burnt sienna, chrome yellow and ponceau 2R. affect artificial digestion with pepsin when used in quantities of 1 part of the color or less to 400 parts of the food. The results also indicate that the synthetic colors are less active than animal and mineral colors and not more active than vegetable colors. Vegetable and synthetic colors are directly digested by pepsin and by pancreatin, and when the amount of color exceeds 1 part to 200 a correction is necessary, increasing the factor of digestibility 10 to 40 points.

On Folin's theory of proteid metabolism, D. N. PATON (*Jour. Physiol., 33 (1905), No. 1, pp. 1–11, figs. 3*).—From experimental and other data presented, the author concludes that the theory of proteid cleavage advanced by Folin (E. S. R., 17, p. 167) regarding protein metabolism should not be based too exclusively on the distribution of nitrogen in the urine of the subjects examined, but that the possibility of urea being an end product of both exogenous and endogenous metabolism should be considered.

Strength and diet. A practical treatise with special regard to the life of nations, R. RUSSELL (*New York and Bombay: Longmans, Green & Co., 1905, pp. 649*).—A vegetarian treatise.

Cooking by cold: Some studies, E. CUTTER (*Dietet. and Hyg. Gaz., 22 (1906), No. 2, p. 79*).—Tests are reported from which the author concludes that freezing potatoes, onions, cranberries, and squashes changed some starch into dextrose.

The effects of high external temperatures on the body temperature, respiration, and circulation in man, A. E. BOYCOTT and J. S. HALDANE (*Jour. Physiol., 33 (1905), No 1, Proc. Physiol. Soc., 1905, p. XII*).—In experiments with man the body temperature in still air was found to rise above normal when the wet-bulb thermometer rose above 31° C., while it remained normal whatever the external temperature might be, provided the wet-bulb thermometer did not rise above 31°.

"The more the wet-bulb thermometer rose above 31° the more rapidly did the body temperature rise. In moving air the wet bulb thermometer could be allowed to rise to about 35° or a little higher without the body temperature rising above normal. With rise of body temperature a marked fall in the alveolar CO_2 pressure was observed. With rise of body temperature there was a very marked increase in the pulse rate, along with a slight or tolerably marked rise in the blood pressure."

Rice flour sold in France (*Bul. Agr. Algérie et Tunisie, 11 (1905), No. 22, pp. 503–506*).—Notes on the use of rice flour as an adulterant of wheat flour.

The carbohydrates of marine algæ and products made from them, J. König and J. Bettels (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 8, pp. 457–473*).—From an extended study of edible birds' nests and of marine algæ and their products, agar-agar, and nori, the conclusion was reached that the edible birds' nests have an entirely different composition from the marine algæ products to which they have much resemblance.

In contrast to the marine algæ products the edible birds' nests contain no galactan and only a small amount of carbohydrates as a whole (15 to 20 per cent). On the other hand, the percentage of nitrogenous material resembling mucin is high (50 to 60 per cent). It may be said, therefore, that edible birds' nests are a true animal product.

Barley grits and pearl barley from sulphured grain, T. Wetzke (*Ztschr. Öffentl. Chem., 11 (1905), p. 22; abs. in Hyg. Rundschau, 15 (1905), No. 23, p. 1219*).—Examination of a number of samples showed that the amount of sulphurous acid remaining in grits and pearl barley made from sulphured grain was very small and the author believes therefore that such goods would not be unwholesome.

Cheese as an article of diet. Fancy cheeses, J. G. McMillan (*Jour. Dept. Agr. Victoria, 3 (1905), No. 10, pp. 703–713, pls. 2, figs. 4*).—The author points out that cheese is a very nutritious food from the standpoint of protein and energy. Data regarding the composition of different sorts of cheese are quoted and the possibilities of increasing the local consumption of cheese and other questions are spoken of. The author believes that the manufacture of fancy cheeses would prove profitable in Victoria, and detailed directions are given for making a number of sorts.

Tannin in coffee, C. D. Howard (*N. H. Sanit. Bul., 2 (1906), No. 10, pp. 163–165*).—Analyses of coffees from which it is claimed tannin or tannin and caffein has been removed were made, as well as of ordinary coffee and coffee chaff, with a view to ascertaining whether the removal of the chaff or other special treatment diminishes the tannin content as is frequently claimed.

The coffee chaff examined contained 5.98 per cent caffetannic acid, a mixture of Java and Mocha coffee 11.17 per cent, and the specially prepared coffees from 7.61 to 11.04 per cent. In the author's opinion the figures show plainly that the exclusion of the chaff would not mean freedom from tannin. "The only practicable method by which the caffetannic acid could be extracted is that of treatment with hot water, and this process would involve the simultaneous removal of the caffein."

Chemical and sanitary studies of oils used as food in Riga, F. Ludwig (*Farm. Zhur. [St. Petersb.], 43 (1904), p. 209; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 9, p. 562*).—The results of analyses of a number of samples of hemp seed oil, sunflower seed oil, mustard seed oil, and Provence oil are reported. All were found to be fresh and unadulterated.

Condiments and their active principle, P. Martens (*Pure Products, 2 (1906), Nos. 1, pp. 9–13; 2, pp. 62–67*).—Data are summarized regarding the composition of spices, tea, coffee, tobacco, and other condiments and stimulants with special reference to the essential oils, alkaloids, and other bodies to which their specific flavor or action is due.

Experiments in blanching vegetables, T. Zschokke (*Landw. Jahrb. Schweiz, 19 (1905), No. 9, pp. 619, 620*).—When vegetables are canned on either a large or a small scale it is customary to cook them in water until soft, i. e., to blanch them before processing in cans. This preliminary cooking removes more

or less coloring matter and nutritive material also, which is to be regarded as a loss since the water is not used.

Comparative tests were, therefore, made with carrots, beans, and peas to see whether the losses could not be avoided if the vegetables were steamed. The samples cooked by steaming were found to be soft 3 to 5 minutes before the samples cooked in water. The water in which the vegetables were boiled was cloudy and of a green color in the case of beans and peas, and of a yellow color in the case of carrots. When the vegetables were steamed, the water in the steamer was neither cloudy nor colored.

As shown by analyses of the water in the 2 cases, the total amount of material extracted from boiled carrots was 3.75 per cent, peas 3.31 per cent, string beans whole 1.008 per cent, and string beans cut up 1.208 per cent. In the case of the steamed vegetables the quantities were carrots 0.69 per cent, peas 0.688 per cent, string beans whole 0.286 per cent, and string beans cut up 0.227 per cent. The amount of protein, nitrogen-free extract, and mineral matter (potassium oxid and phosphoric acid) in the dry matter was determined, and nitrogen-free extract was found to be the principal constituent.

Results of examination of canned vegetables, O. Schütte (*Pure Products, 2 (1906), No. 1, pp. 21–26*).—A report of the examination of 19 samples of canned asparagus, peas, string beans, corn, tomatoes, and mushrooms. All but 3 of the samples were American goods. Most of the samples were of good quality and free from added preservatives. The 2 samples of mushrooms examined (French products) had a putrid odor and were badly decomposed, though they were free from bacteria. In the author's opinion they were unfit for use.

The dangers attending the use of spoiled canned goods are spoken of.

Regarding canned asparagus, the author notes that "while some degree of corrosion can scarcely be avoided when asparagus is preserved in tins, the discoloration of the vegetable indicates a contamination too serious to be overlooked; at any rate the pieces showing a marked discoloration should not be used."

Report on food products for 1905, B. W. Kilgore (*Bul. N. C. Dept. Agr., 26 (1905), No. 12, pp. 35*).—In addition to a general summary of the work undertaken in 1905 under the provisions of the State pure-food law, the bulletin contains the following special articles: Vinegar, Examination of Canned Corn, Examination of Olive and Other Table Oils, and Malts, Beers, Phosphates, Ciders, Tonics and Bitters, by W. M. Allen; and Maple Sugar and Sirup, by J. M. Pickel.

The total number of samples of food products and beverages examined was 179, and of these 40.22 per cent were found to be adulterated. Of the 52 samples of vinegar examined 34 were found to be as represented. Twenty-nine samples of canned corn were tested for chemical preservatives but none was found. Of the 14 samples of table oils examined, 12 sold as olive oil were apparently true to name. Two samples were labeled salad oil and apparently consisted largely, if not entirely, of cotton-seed oil. Thirteen out of the 15 samples of maple sirup examined were found to be adulterated—12 with cane sugar, while one, as stated on the label, contained glucose. Of the 2 samples of maple sugar examined one was found to be adulterated.

Report of food and drug inspection, C. D. Howard (*N. H. Sanit. Bul., 2 (1906), No. 10, pp. 158–163*).—A number of samples of oysters, cider vinegar, mincemeat, chocolate candy, and drugs were examined.

"When the work of examining oysters was commenced at the State Laboratory of Hygiene 2 years ago, we found 44 per cent of the samples collected as fresh oysters to be preserved with borax or preservaline. Several cases of ill-

ness were reported from their use. The gradual reduction of this unlawful adulteration to 7 per cent, in the face of protestations from the wholesale houses that the business could not be carried on without using preservatives, shows their claims to be false, and exhibits in a limited measure the results of the work."

The fate of boric acid in the body, E. ROST (*Arch. Internat. Pharmacod. et Thér., 15 (1905); abs. in Brit. Med. Jour., 1906, No. 2352, Epit., p. 16*).—The investigations reported led to the conclusion that the kidneys are practically the only channels by which boric acid is eliminated, the quantity occurring in the saliva, milk, and feces being very small.

Of the total amount of boric acid administered, 50 per cent was eliminated in the urine in 12 hours. Boric acid does not disappear from the body as rapidly as has been thought, since the remaining portion was not excreted for 3 or 4 days, and if boric acid be repeatedly taken, in the author's opinion, it may accumulate in the body.

The necessity for a national pure-food law, E. GIRARD (*Dietet. and Hyg. Gaz., 21 (1905), No. 11, pp. 656–658*).—In connection with an address on the need of a national pure-food law delivered before the annual convention of the International Stewards' Association, the author states that when pigs and other animals were given food artificially colored in the same way and to the same extent as human foods they failed to make satisfactory gains in weight and showed other unfavorable symptoms, whereas such was not the case with control animals fed food without artificial coloring matter and preservatives. Some of the animals were shown. When the test was reported a pig receiving pure food weighed 140 lbs. and an animal which had received the preservative and coloring matter weighed only 85 lbs.

Foods and food control, W. D. BIGELOW (*U. S. Dept. Agr., Bur. Chem. Bul. 69, rev. ed., pts. 1–8, pp. 704*).—This compilation of the State and Federal laws regarding foods and food control has been revised to July 1, 1905.

ANIMAL PRODUCTION.

Licensed commercial feeding stuffs, 1905, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Bul. 130, pp. 1–50*).—The licensed feeds examined in 1905 included linseed meal, cotton-seed meal, gluten feeds, hominy feeds, corn and oat feeds, oat feeds, dairy feeds, calf feeds, molasses grains, and meat meal and other poultry feeds.

The unlicensed feeds, feeds not subject to license, and the miscellaneous materials examined included ground rice hulls, mixed rice feed, rice bran, rice middlings, speltz hulls, dried brewers' grains, molasses feeds, malt sprouts, proprietary poultry feeds, blood flour, bone meal and other poultry feeds of animal origin, distillers' grains, molasses grains, gluten feed, wheat bran, wheat middlings, mixed bran and shorts, Red Dog flour, ground corn and oats, corn meal, oats (whole and ground), barley, barley bran, barley feeds, ground barley and oats, rye shorts, ground flaxseed, and wheat screenings.

One of the so-called cereal oil meals examined was found to consist of finely ground rice hulls apparently impregnated with a cheap oil, either rape seed oil or rice oil.

"Twenty-four samples out of 129 collected, of 45 different brands, were found deficient in protein and fat, 58 in protein alone and 10 in fat alone; that is, 82 samples, or 64 per cent of the total number [of licensed feeds], contained less protein than guaranteed . . . and 34 samples, or 26 per cent of the total number, contained less fat than the guaranty. . . . Deficiencies occurred in the

case of 45 different brands. Since samples of 58 different licensed brands were collected and analyzed during the year, we find that 69 per cent of the brands (40 different brands) were deficient in protein and 33 per cent (19 different brands) were deficient in fat. These figures are strikingly large and furnish conclusive proof that the various manufacturers of licensed feeding stuffs do not pay much attention to the chemical composition of the feeds which they put on the market in this State and generally place their guaranties for valuable food components considerably higher than they have reason to expect the feeds will reach. The figures also give evidence of the indifference of buyers of feed as to whether the guaranties of the manufacturers are met or not. No permanent improvement in this respect can be hoped for until purchasers of concentrated feeds post themselves more thoroughly in regard to the composition of the various feeds and come to appreciate the value of high-grade feeding stuffs. When this change occurs, the cost of the feed will becomes of less importance than it is now, for buyers will realize that feeds of good quality can not be sold at cheap prices. . . . No serious adulterations of concentrated feeding stuffs are practiced in this State, so far as we have been able to ascertain; the admixture of screenings to mill feeds, especially bran, is still practiced by a few mills, but the quality of the mill feed sold in our State is, on the whole, of a high grade."

The inspection of feeding stuffs in Wisconsin and some of the results so far obtained, F. W. Woll (*Wisconsin Sta. Bul. 130, pp. 51–70*).—The importance of laws regulating the sale of feeding stuffs, the operation of the Wisconsin State law, and similar questions are spoken of, as well as the character of the feeding stuffs sold in Wisconsin and related topics. While a large proportion of the feeding stuffs, including the wheat bran and other by-products which are so important, are of good quality, many instances of adulteration were found. "Ground rice hulls have recently been introduced into the State and, but for prompt action on our part, would be likely to have found their way into the ground feed on our market and may do so yet in spite of our efforts. . . . As rice hulls are a dangerous feed and we have records that cattle have died after eating large quantities thereof, we thought it our duty to call public attention to the danger of these ground hulls finding their way into mixed feeds sold in the State and to put our farmers and others on their guard."

Foods for live stock (*Jour. Jamaica Agr. Soc., 9 (1905), No. 12, pp. 447, 448*).—Analytical data regarding composition of local-grown corn and guinea corn are reported, and the importance of local feeding stuffs is discussed. It is pointed out that guinea corn is an important stock feed, and as a forage crop it is claimed that it is more valuable than corn. "Hay grass," it is said, is also a valuable feed, the young crop being especially rich in protein.

"Bamboo leaves are another very good fodder. If in places where drought in the spring is feared, the clumps that often dot pastures were at the end of the October seasons cut down and fired, from the roots would spring up a mass of rich vegetation, producing fodder through the driest weather. St. Mary grass and the coarse guinea grass, sometimes called Cow Grass, are more nutritious than is generally thought and form valuable fodders, not of much less value than the best guinea grass."

Barley, F. Barnstein (*Landw. Vers. Stat., 63 (1905), No. 3–4, pp. 275–305, figs. 18*).—A summary of data on the origin and distribution, chemical composition, digestibility, feeding value, botanical structure, uses of barley and barley products, and related questions.

Digestion experiments, W. P. Gamble (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 100–103*).—The composition and digestibility of

green or uncured corn, field-cured corn, and silage were studied, the average coefficients of digestibility obtained with steers being as follows:

Average coefficients of digestibility of corn products—Experiments with steers.

	Dry matter.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Green or uncured corn fodder	74.60	73.47	83.02	76.08	75.28
Field-cured corn fodder	72.57	73.27	85.73	74.92	71.70
Corn silage	70.08	66.24	82.48	71.86	74.23

"The loss sustained when corn is cured in the fields and in the silo is about equal. There is a decrease in the digestibility of corn fodder in curing it. There is little difference in the digestibility of field-cured corn and ensilage.

"The foregoing conclusions lead to the belief that silage is the best form in which the farmer can save his fodder corn; because, first, it is succulent and palatable, and the animals eat it much more readily than field-cured corn; second, the cost of putting corn into the silo is but slightly greater than that of curing it in the field; third, silage is always in a convenient form to feed; and, finally, the loss in the silo is not likely to be as great as the loss in the field, where the wind blows a certain amount of it away. A further loss is sustained in that part of the fodder frozen to the ground and any bundles that fall are almost, if not entirely, rendered useless as food."

Brief statements are made regarding the work at the college.

Investigations on the nutritive value and digestibility of cotton-seed meal containing an abundance of hull and dried yeast residue, F. Honcamp, M. Popp, and J. Volhard (*Landw. Vers. Stat., 63 (1905), No. 3-4, pp. 263-274*).—In experiments with sheep the average coefficients of digestibility for undecorticated cotton-seed meal were: Protein, 73.2 per cent; ether extract, 100 per cent; nitrogen-free extract 54.6 per cent, and crude fiber, 23.1 per cent; and for dried yeast residue: Protein, 86.6 per cent, ether extract, 38.2 per cent, and nitrogen-free extract, 81.5 per cent.

Experiments on the comparative digestibility of meadow hay and oat straw by cattle and sheep, O. Kellner et al. (*Landw. Vers. Stat., 63 (1905), No. 3-4, pp. 313-319*).—Meadow hay was more thoroughly digested by steers than by sheep, as were also the oat straw constituents, with the exception of ether extract.

The digestibility of different materials used to absorb molasses, with special reference to the metabolism of mineral matters, T. Pfeiffer and A. Einecke (*Mitt. Landw. Inst. Breslau, 3 (1905), No. 4, pp. 547-565*).—Since wood meal and peat meal are both used as carriers of molasses in commercial feeding stuffs, the influence of these materials on the digestibility of rations was tested with sheep.

It was found that wood meal lowered the coefficients of digestibility of the ration, no marked difference being observed between raw wood meal and that which had been cooked under pressure. As in earlier work (E. S. R., 16, p. 291), it was found that peat meal contains only small amounts of digestible nutrients. In connection with the work the balance of income and outgo of sodium and potassium was determined.

Spontaneous combustion of hay, K. H. M. van der Zande (*Milch Ztg., 34 (1905), No. 45, pp. 550-552, figs. 2*).—The investigation reported has been previously noted (E. S. R., 16, p. 1004).

On the contents of lime and phosphoric acid in feed rations, S. HALS (*Norsk Landmandsblad, 24 (1905), No. 45, pp. 567, 568*).—The author shows that concentrated feeds as a general rule are low in lime and high in phosphoric acid, while the opposite holds true with coarse feeds. Where large quantities of concentrated feeds are fed, there is therefore a danger of supplying too little lime for the needs of the animals.

In the case of milch cows producing 10 kg. of milk per day, the lowest quantities required would be about 70 gm. of lime and 45 gm. of phosphoric acid. This deficiency can be made good by adding mineral matter to the ration. For supplementing rations relatively low in lime, precipitated dibasic calcium phosphate is recommended as superior to bone meal, bone ash, or similar very indigestible materials.—F. W. WOLL.

Experiments in calf feeding (*Queensland Agr. Jour., 16 (1905), No. 3, pp. 252–255*).—The feeding value of 3 sorts of commercial calf feeds was studied in comparison with pollard, the different feeding stuffs being fed with skim milk. In 2 of the tests the calves were finished on a mixture of whole and skim milk. Generally speaking, the gain on pollard and skim milk was greater than on commercial feeds and was more cheaply made.

The utilization of skim milk for calf feeding, A. PIROCCHI (*Rev. Gén. Lait, 5 (1905), No. 3, pp. 49–58*).—Using calves 8 to 41 days old, the value of rice flour, corn meal, and starch as supplements for skim milk were studied. The greatest gain per head per day was 0.97 kg. by one of the calves on maize meal and the smallest gain, 0.76 kg., by one of the calves on rice meal. The flesh of the calves fed maize and flour was superior to that of the calves fed rice flour from a market standpoint.

Cattle feeding (*Verslag. en Meded. Afdeel. Landb. Dept. Landb., Nijv. en Handel, 1905, No. 6, pp. 63, map 1*).—This summary of information on cattle feeding contains the following articles: Government Methods Adopted in 1904 for Encouraging the Cattle Industry, by F. B. Löhnis; The Improvement of Cattle, by H. M. Kroon; and The Cattle Industry of Belgium, by S. Koenen and H. Mayer Gmelin.

Experiments in steer feeding, J. A. CRAIG and F. R. MARSHALL (*Texas Sta. Bul. 76, pp. 23, figs. 4*).—Tests were made with 8 lots of 5 cattle each in 1903 and 8 lots of 5 and 2 of 19 each in 1904, the 2 larger lots being fed on pasture. Materials of interest to southern feeders, namely, rice by-products, hay of different sorts, and molasses were studied, the special rations being compared with a standard ration of cotton-seed meal and cotton-seed hulls. The lots on pasture were fed for 196 days; the others 60 to 100 days.

In the first test with rice bran, this material replaced cotton-seed meal in the proportion of 3:2, and cotton-seed hulls constituted the coarse fodder. The average daily gain per head was 2.17 lbs. and the cost of a pound of gain 4.6 cts. On cotton-seed meal and hulls similar values were 2.21 lbs. and 4.61 cts. The average daily gain on rice bran substituted for cotton-seed meal in about the proportion of 2:1 was 2.98 lbs. and the cost of a pound of gain 3.14 cts. as compared with 2.88 lbs. and 3.23 cts. on cotton-seed meal and hulls.

When rice bran was added to a ration of cotton-seed meal and hulls, the quantity of the bran being nearly half that of the meal, the average daily gain was 3 lbs. as compared with 2.6 lbs. on cotton-seed meal and hulls only, the cost of a pound of gain in the 2 cases being 3.9 and 4.1 cts.

Substituting rice polish for a part of the cotton-seed meal in a standard ration resulted in an average daily gain of 2.29 lbs., the cost of the gain being 4.5 cts. per pound; that is, the gain was somewhat greater and the cost less

than the values reported for a ration of cotton-seed meal and hulls. The maximum amount of rice polish eaten was 2.5 lbs. per head per day.

The feeding value of rice hulls was also studied. It was the intention to substitute these for cotton-seed hulls, but the cattle would not eat a sufficient quantity and the ration finally selected consisted of rice hulls, cotton-seed hulls, cotton-seed meal, and rice bran. The average daily gain was 1.86 lbs. and the cost of a pound of gain 4.35 cts. On a similar ration without the rice hulls the average values were 2.17 lbs. and 4.6 cts.

When sorghum hay, cowpea hay, and peanut hay were tested as substitutes for cotton-seed hulls, the grain ration, consisting of cotton-seed meal and rice bran, the greatest gain, 2.35 lbs. per head per day, was obtained with sorghum, the cost of a pound of gain being 4.6 cts., similar values on a ration of rice bran, cotton-seed meal, and cotton-seed hulls, selected for comparison, being 2.98 lbs. and 3.1 cts. The least satisfactory gain, 1.86 lbs. per day at a cost of 4.5 cts., was obtained with peanut hay. A test with prairie hay was also made, but as it covered only 4 weeks final conclusions were not drawn. The average daily gain was 3.44 lbs. per head.

In a 100-day trial, alfalfa hay and corn-and-cob meal, a typical corn-belt ration, were compared with cotton-seed meal and hulls, a typical cotton-belt ration, the average gain per head in the 2 cases being 2.53 and 2.21 lbs. and the cost of feed per pound of gain 7 and 4.6 cts. "It will be seen . . . that alfalfa and corn-cob meal produce slightly more satisfactory gains, but, under conditions existing in the greater part of Texas, it will hardly be possible to make a pound of gain as cheaply as on a ration consisting of cotton-seed meal and hulls."

The average daily gain on a ration of molasses with cotton-seed meal and hulls was 3.1 lbs. per head at a cost of 4.52 cts. per pound as compared with 2.59 lbs. and 4.66 cts. on a similar ration without the molasses.

Shelled corn, ear corn, and cotton-seed meal supplementing pasturage gave better results than the corn alone, the average daily gain in the 2 cases being 1.1 lbs. and 0.87 lb. and the cost of a pound of gain 3.6 and 4.6 cts.

In these trials part of the animals fed were yearlings and the others two-year-olds. "Yearling steers in comparison with two-year-old steers on rations of cotton-seed meal and hulls made about the same gain at a little cheaper cost. The two-year-old steers gained 2.59 lbs. per head daily and the yearlings 2.21 lbs."

Silage, hay, and stover in beef making, A. M. SOULE and J. R. FAIN (*Virginia Sta. Bul. 157, pp. 35–64, figs. 10*).—Corn silage, corn stover, and timothy hay were compared, as were also linseed meal and cotton-seed meal, supplementing corn-and-cob meal, the rations being so arranged that each of the coarse fodders was fed with the 2 grain mixtures.

The 6 lots used in the trial were each made up of 5 steers and 5 heifers, and the test covered 180 days. The largest gain, 1.59 lbs. per animal per day, or 1.66 lbs. per steer and 1.51 lbs. per heifer, was obtained with the lot fed silage with corn-and-cob meal and linseed meal. The lot fed silage with cotton-seed meal in addition to corn-and-cob meal did not do as well, gaining only 1.33 lbs. per head per day on an average, or 1.35 lbs. per steer and 1.3 lbs. per heifer. These two rations, the authors point out, were decidedly superior to the others tested.

The ration containing shredded corn stover and linseed meal gave an average daily gain of 0.93 lb. per head, and that containing shredded corn stover and cotton-seed meal a gain of 1.01 lbs. On the ration containing timothy hay and corn-and-cob meal with linseed meal and cotton-seed meal, respectively, the gains were 1.15 lbs. and 1.05 lbs. per head per day.

Considering the results as a whole, the silage-fed cattle made an average gain of 1.46 lbs., the stover-fed cattle 0.97 lb., and the hay-fed cattle 1.10 lbs. per head per day.

"There was a difference of from 0.3 to 0.5 of a pound of gain per head per day in favor of the silage-fed cattle. They also finished out better and in any discriminating market would certainly bring a better price than the dry-fed cattle.

"Of the three forms of roughness fed, the silage was eaten with the greatest relish and there was absolutely no loss, whereas with the stover the loss amounted to 13.5 per cent, and with hay 4.16 per cent. Where a larger number of animals are fed this would make a considerable difference in the cost of ration, except that the shredded stover can be utilized to advantage for bedding.

"That the cattle fed were not of a satisfactory quality is evidenced by these results. . . .

"Considered on the basis of the content of digestible protein there is little to choose between linseed meal and cotton-seed meal for balancing up the corn-and-cob meal, which must of necessity constitute the basis of a ration for beef cattle in the South. The relative cost of the foods will determine which one to select."

Draft cattle, M. Ringelmann (*Jour. Agr. Prat., n. ser., 11 (1906), No. 2, pp. 43–48*).—A summary of information regarding the feeding of draft cattle, with special reference to the rations fed and related topics.

Sheep feeding experiments, W. Bruce (*Edinb. and East of Scot. Col. Agr. Bul. 8, pp. 1–34*).—A test previously reported on the comparative value of different kinds of cotton-seed cake and other grains, the second experiment in all practical details confirming the earlier work (E. S. R., 17, p. 68).

Live stock, G. E. Day (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 136–142*).—Brief statements are made regarding the farm animals kept and sold, and feeding experiments with pigs are reported.

In a study of blood meal, tankage, skim milk, and skim milk and tankage, fed with mixed meal as compared with mixed meal alone, made with 5 lots containing 7 or 8 pigs, it was found that the gain ranged from 122.4 lbs. per pig on meal only to 163.8 lbs. on skim milk, tankage, and mixed meal. The meal ration was most expensive, a pound of gain costing 4.81 cts., and the tankage and meal ration least expensive, a pound of gain costing 4.29 cts. This is a duplicate of a test previously reported (E. S. R., 17, p. 173) and consumed over 5 months.

In a study of pen feeding *v.* pasturage, a lot of 8 pigs was turned on a rape pasture and fed a light grain ration in comparison with the lot fed meal indoors in the above test. The pasture-fed lot made an average gain of 108.6 lbs. per pig at a cost of 5.51 cts. per pound. "Though the pigs on the exclusive meal ration made somewhat expensive gains, those on pasture proved a great deal more expensive. Pasturing proves very satisfactory for matured or comparatively well matured pigs, and is beneficial in promoting health and general vigor, but for young, growing pigs all our work goes to show that it is vastly more economical to restrict the amount of exercise and to feed the pigs green food with their meal ration."

In connection with the feeding experiments, data are recorded regarding the cost of raising pigs. The average cost of raising pigs 6 weeks old was $1.31 per head, and the total cost when finished for market $4.52 per 100 lbs. In another instance recorded, the cost when finished was $3.86 per 100 lbs. These values are regarded as tentative.

Pig feeding experiments, C. L. Beach and H. L. Garrigus (*Connecticut Storrs Sta. Bul. 39, pp. 29–37, figs. 4*).—In the first of the tests reported

grain and skim milk each fed alone were compared with grain and skim milk 1:4 and 1:8, the test being made with 4 lots of 3 pigs each and covering 86 days. The average daily gain ranged from 0.47 lb. on grain only to 1.38 lbs. per head on grain and skim milk 1:4. The cost of a pound of gain ranged from 4.2 cts. on the last mentioned ration to 5.48 cts. on skim milk only.

Four feeding trials were reported each with 2 lots of 3 or 4 pigs, one lot being fed grain and skim milk 1:3 or 4 and the other in the proportion of 1:7 or 8. The average duration of the tests was 114 days. With the larger proportion of skim milk the average daily gain was 1.10 lbs. per head and with the smaller proportion 1.27 lbs., the cost of a pound of gain in the 2 cases being 4.45 and 4.95 cts. Considering all the lots the average amount of feed required per pound of gain was 2.53 lbs. grain and 10.86 lbs. skim milk. The gains made by the pigs in different periods were considered. In the case of most of the pigs the relation of dressed to live weight was recorded and found to be 75 per cent on an average.

Fattening pigs and wintering brood sows on alfalfa and a grain ration, H. R. Smith (*Nebraska Sta. Press Bul. 20, pp. 4*).—The value of cut alfalfa hay and ground alfalfa hay as substitutes for grain was tested with 8 lots of 7 pigs each, the rations consisting of corn meal, alone and with shorts, bran, cut alfalfa hay, and ground alfalfa hay, the proportions in which the other feeding stuffs were combined with the corn meal being 3:1 and 1:1.

In the 12 weeks of the test the average daily gain per pig ranged from 0.8 lb. on corn meal and bran 3:1 to 1.096 lbs. on corn meal and shorts 3:1. However, nearly as large gains were made when alfalfa hay formed a part of the ration amounting to 1.071 lbs. and 1.062 lbs., respectively, with corn meal and cut alfalfa hay 3:1 and corn meal and ground alfalfa hay 3:1. The feed required per pound of gain ranged from 4.06 lbs. with corn meal and shorts 3:1 to 5.89 lbs. with corn meal and bran 3:1, and the cost of a pound of gain from 2.62 cts. with corn meal and cut alfalfa hay 3:1 to 3.96 cts. with corn meal and ground alfalfa hay 1:1.

"The largest daily gains were made on three-fourths corn and one-fourth shorts, but a gain practically equivalent was made at a lower cost where [a like proportion of] either cut or ground alfalfa was substituted for shorts in the ration. The cheapest gains were made on corn and cut alfalfa. Bran does not prove equal to either shorts or alfalfa when fed as one quarter of the ration to pigs.

"A ration three-fourths corn and one-fourth alfalfa produces greater gains than when one-half alfalfa is fed. Where alfalfa is raised on the farm, and when there is no particular need to hasten growth in the pigs, a ration one-half alfalfa hay and one-half corn may give cheaper gains than when a heavier corn ration is fed.

"Hogs which have been raised largely on alfalfa pasture will learn to eat the hay in winter without cutting with a machine and to depend largely upon it where only a limited grain ration is fed, but a ration wholly alfalfa does not seem to give economical results.

"This experiment shows that cut or ground alfalfa can be substituted for shorts at the same price in fattening pigs."

In another test a lot of 10 young sows were fed for 8 weeks corn meal and ground alfalfa hay 1:1, in comparison with a similar lot of 11 sows fed like proportions of ground barley and ground alfalfa hay. The average daily gain on the corn-meal ration was 0.98 lb. per head and on the barley ration 0.84 lb. "Both these lots made fine gains and at farrowing time produced large, strong litters, showing that the rations had been nearly ideal . . . for brood sows."

In a third test, 13 brood sows averaging 258 lbs. each were fed a ration of 2

lbs. corn meal and 6 lbs. of cut alfalfa hay throughout the winter. At the end of the fifth week, when the sows began to farrow, the average weight was 264 lbs. "These sows kept in fine condition, farrowing during February and March, and saved large litters in every case. They were fed a ration one-half corn or barley and one-half alfalfa while suckling pigs.

"These several experiments, including 113 animals in all, give excellent proof of the high nutritive value of alfalfa supplemented by a small corn ration."

Experiments on the rational feeding of army horses, H. VAN DE VENNE (*Rapport sur des expériences d'alimentation rationelle du cheval de troupe. Brussels: H. Lamertin, 1905; rev. in Centbl. Agr. Chem., 34 (1905), No. 12, pp. 825–829*).—The possibility of substituting for oats a commercial feed made up of 60 per cent molasses, 20 per cent corn feed, and 20 per cent linseed meal was studied with horses belonging to the military and war school at Brussels.

Judged by the weight of the animals, the author concluded that the normal ration made up of 5.5 kg. oats, 0.6 kg. bran, 3.0 kg. hay, and 0.2 kg. chopped straw was sufficient for their needs. When about half the oats was replaced with the molasses feed somewhat greater gains were made than on the normal ration. The molasses ration had no marked effect on the amount of water consumed.

The influence of crushing on the digestibility of oats, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 10 (1905), No. 51, pp. 777–779, fig. 1*).—According to the author's investigations crushing oats increases their digestibility when fed to horses. He states that they have been fed with satisfactory results for some years by the Paris Cab Company and have effected a decided saving.

Report of manager of the poultry department, W. R. GRAHAM (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 228–239, figs. 5*).—The class-room work in poultry and the general treatment of the college breeding stock are discussed, and experimental work with incubators, with poultry houses, and with different rations for fattening chickens is reported.

Many of the incubator chickens were affected with white diarrhea, and it seemed possible that incubators operated in badly ventilated rooms were the cause, though the experiments undertaken did not lead to definite conclusions. However, well-ventilated rooms which are not very moist, an even temperature for the incubators, and fresh air for the chickens from the first day of hatching are recommended, as well as healthy eggs from vigorous stock and the avoidance of sloppy foods. Scalded milk, boiled rice, and rice water are, in the author's opinion, at times excellent preventives for this trouble, which was apparently not of bacterial origin.

When different sorts of poultry houses were tested, "the use of straw over-head was effectual in keeping the houses dry. The coldest house . . . proved to be the most satisfactory in both the number of eggs produced, the fertility of the eggs, and also in the general health of the birds. . . . Grass runs at the north of the houses are not equal to runs on the south, especially in the late autumn when the wind blows in one door and out of the opposite."

The rations used for fattening chickens are described, and the results obtained with a number of rations mixed with sweet skim milk, sour skim milk, whey, and water are given, 19 lots of 12 chickens each being used and the test covering 3 weeks. A ration of equal parts corn meal, oatmeal, and shorts mixed with whey was the cheapest, a pound of gain costing 4 cts. A mixture of equal parts of ground corn, oats, and barley mixed with water was the dearest, a pound of gain costing 12.34 cts. The grain required per pound of gain was also greatest with this ration, being 10.73 lbs. The smallest amount, 2.5 lbs., was required with equal parts of shorts, corn meal, and oatmeal, with 25 per cent of beef

"Sour skim milk, i. e., milk that is thickened, is without doubt the best liquid to mix with grain rations where a uniform product is wanted, and more so where white-fleshed chickens are in demand. Sweet skim milk has not a feeding value for grown chickens equal to sour milk. Whey is a better food than is generally considered. The results appear to indicate that it aids digestion. Whey and pork scrap have not given the results expected, and . . . this combination [is not recommended]. Where pork scrap and beef scrap can be procured at reasonable cost, say 2 cts. or less per pound, they are good value, especially where a yellowish flesh is in demand. Grain mixtures only mixed with water are not economical considering this test."

Artificial incubation, E. BROWN (*Jour. Bd. Agr. [London], 12 (1905), No. 2, pp. 87–96, fig. 1, dgms. 3*).—The results of incubation experiments carried on at the Reading College Poultry Farm are summarized.

"The results of the year's operations have been eminently satisfactory, and to secure with so large a number an average of 75.82 per cent is indicative of the success attending the use of artificial methods of hatching under suitable conditions and with well-made reliable machines.

"Hens have chiefly been employed for the hatching of ducklings, and the extent of observations with incubators was too limited to make any special records."

Hints to poultry raisers, G. A. BELL (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 82, pp. 3*).—Varieties, poultry houses, feeding of hens, and the feeding of young chicks are the topics discussed in this general summary of data.

The marketing of poultry products, F. H. STONEBURN (*Connecticut Storrs Sta. Bul. 38, pp. 28, figs. 8*).—In this discussion of marketing poultry products, the author considers choice of markets, prices, methods of classifying and packing eggs, methods of killing, dressing, and shipping poultry, market conditions with reference to chickens of different ages, capons, turkeys, geese, ducks, guinea fowls, and squabs, and related questions.

The author calls attention, in discussing the utilization of by-products, to the fact that the fresh blood obtained when the chickens are killed may advantageously be fed to live poultry. "Because of the high percentage of protein it contains, it is especially valuable as food for laying and young stock. It can be most conveniently fed by mixing in the mash feed."

The losses in weight in killing and dressing 554 cocks, cockerels, hens, and pullets were recorded. On an average the weight of the birds bled and plucked was 9.4 per cent less than the live weight. With the intestines, head, and feet removed, the dressed birds weighed 25.2 per cent less than alive.

Poultry and pigeon-squab combination, M. K. BOYER (*Rel. Poultry Jour., 12 (1906), No. 12, pp. 1245–1248, figs. 5*).—On the basis of experience, the author believes that squab and poultry raising may be successfully combined. The care of breeding stock, preparation of squabs for the market, and related questions are discussed.

Breeding wood ducks, S. D. TALBOT (*Rel. Poultry Jour., 12 (1906), No. 11, p. 1128*).—On the basis of experience the author states that wood ducks can be successfully raised in captivity.

A yard having bushes as shelter should be provided and inclosed with netting. In short, an attempt should be made to approximate their natural surroundings as closely as practicable. A house is not needed, but some shelter is useful in winter. The birds do not lay until they are two years old. The yards should be covered with wire netting, or if this is not convenient the wing may be unjointed at the first joint to prevent flight.

Raising guinea fowls, JENNIE O'CONNER (*Texas Farm and Ranch, 25 (1906), No. 5, p. 14*).—In a discussion of the feeding and care of guinea fowls the

author states that mites and lice are more dangerous for these birds than for other classes of poultry and that precautions should be taken to keep them free from such pests.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Gluten and cotton-seed meal with silage, hay, and stover for dairy cows, A. M. SOULE and J. R. FAIN (*Virginia Sta. Bul. 156, pp. 30, figs. 16*).—The author reports a feeding experiment and discusses at some length the feeding of dairy cows with special reference to Virginia conditions.

Four lots of 6 cows each were fed experimentally for 120 days. The cows in lot 1 consumed on an average 8.18 lbs. of gluten and corn-and-cob meal, 5.73 lbs. of silage, and 6.57 lbs. of hay; the cows in lot 2, 9.01 lbs. of cotton-seed and corn-and-cob meal, 5.71 lbs. of silage, and 6.45 lbs. of hay; the cows in lot 3, 8.82 lbs. gluten and corn-and-cob meal, 5.76 lbs. silage, and 2.61 lbs. of stover; and the cows in lot 4, 9.85 lbs. of cotton-seed and corn-and-cob meal, 5.52 lbs. of silage, and 3.35 lbs. of stover. Gluten meal was therefore contrasted with cotton-seed meal and hay with stover.

Combining the groups with reference to the hay and stover, it was found that the lowest amount of food consumed per gallon of milk and pound of butter produced was shown by the lots fed hay, and that the net cost of a gallon of milk and a pound of butter was less with the hay ration than with the stover ration. The difference, however, was not marked, indicating clearly, according to the author, that a good quality of corn stover can often be fed with practically as good results as timothy hay.

Combining the lots with reference to the gluten meal and cotton-seed meal the results showed a slight difference in favor of the cotton-seed meal. The total amount of food consumed, as well as the net cost per pound of butter and gallon of milk, was, however, practically the same in each case. At the prices quoted, however, it was considered that the cotton-seed meal should be given the preference.

"The experiment also seems to indicate quite clearly that foodstuffs may be properly compared on the basis of the digestible protein they contain, which is in line with a number of feeding experiments previously made, and would seem to be a safe conclusion to draw."

Dried beet pulp as a substitute for corn silage; dried beet pulp v. dried molasses beet pulp; dried molasses beet pulp v. hominy meal, G. A. BILLINGS (*New Jersey Stas. Bul. 189, pp. 24, pl. 1*).—A comparative test of dried beet pulp and corn silage was made with two lots of two cows each during 2 periods of 15 days each.

The beet-pulp ration consisted of 9 lbs. of pulp, 10 lbs. of mixed hay, 10.5 lbs. of mixed feed, and the silage ration of 45 lbs. of silage, 5 lbs. of mixed hay and the same amount of mixed feed. The pulp ration produced 10.2 per cent more milk and 9.7 per cent more butter than the silage ration, but the cost was greater. On the silage ration the cost of 100 lbs. of milk was 2.8 cts. less and the cost of 1 lb of butter 0.61 ct. less than when the pulp ration was fed.

In the second experiment of a similar nature a comparison was made of dried beet pulp and dried molasses beet pulp, and in the third test dried molasses beet pulp was compared with hominy meal. The last two experiments presented here in abstract form have been noted from another source (E. S. R., 17, p. 394).

Alfalfa hay v. purchased feeds, G. A. BILLINGS (*New Jersey Stas. Bul. 190, pp. 19-31, pl. 1*).—A feeding experiment was made with 8 cows during 60 days for the purpose of securing additional data on the value of home-grown alfalfa hay. Previous comparisons of home-grown and purchased feeds were reported

in Bulletins 148, 161, and 174 of the station (E. S. R., 13, p. 176; 14, p. 604; 16, p. 298).

The alfalfa ration consisted of 14 lbs. alfalfa hay, 35 lbs. corn silage, and 2½ lbs. cotton-seed meal. The purchased feed ration consisted of 40 lbs. corn silage, 7 lbs. cornstalks, 4½ lbs. wheat bran, 4½ lbs. dried brewers' grains, and 2 lbs. cotton-seed meal. The average daily yield per cow on the alfalfa ration was 26.3 lbs. of milk, containing 4 per cent of fat, and on the feed ration 27.3 lbs. of milk, containing 4.15 per cent of fat. With alfalfa hay at $6 per ton (the estimated cost of production) the cost of producing 100 lbs. of milk from this ration was 47.6 cts., while the cost of milk production on the feed ration was 71.8 cts. per 100 lbs. of milk.

The cost of producing 1 lb. of butter on the two rations was respectively 10.17 and 14.86 cts. Comparing the results of the present with the earlier experiments it was found that the saving in cost of production by home-grown feeds over purchased feeds was 22.4 per cent for milk and 20.2 per cent for butter, indicating the great advantage of growing protein feeds.

Forage and soiling experiments, 1904, G. C. Watson and T. I. Mairs (*Pennsylvania Sta. Bul. 75, pp. 12*).—The forage crops grown during the season were as follows: Flat peas, peas and oats, peas and barley, clover, cowpeas and sorghum, and cowpeas. Notes are given on the culture of each of these crops and the yields are reported in tabular form.

The crops were fed to 5 cows and data are given showing the production by each. Similar tests were made in 1902 and 1903 (E. S. R., 15, p. 998; 17, p. 285). Of the crops grown during the 3 years, sorghum and cowpeas produced the largest yield of green substance per acre and alfalfa the greatest weight of air-dry substance. Both crops are considered very satisfactory as green forage. Corn grown as a single crop ranked second in the production of air-dry matter. Field peas and oats are also considered very satisfactory field crops. Flat peas and rape are not recommended. Cowpeas are considered preferable to soy beans.

Feeding experiments with milch cows, J. Hansen (*Landw. Jahrb., 35 (1906), No. 1–2, pp. 125–158*).—Several feeding stuffs were compared by feeding in successive periods in experiments with 6 cows, lasting in all 142 days.

The feeding stuffs used were wheat bran, cocoanut cake, "Maizena," fat-free palm-nut meal, and palm-nut cake. When fed in quantities having the same amount of digestible nutrients, the different feeding stuffs exerted, according to the conclusions reached by the author, a very unequal influence upon the yield of milk. Independent of the amount of nutrients contained, the feeding stuffs were considered as having a specific influence on milk production, both as regards the yield of milk and the fat content of the milk.

As compared with wheat bran "Maizena" increased yield of milk, but decreased the percentage of fat. The cocoanut cake and the residues from the manufacture of palm oil produced practically the same amount of milk as the wheat bran, but increased to a marked extent the fat content of the milk. Compared on the basis of digestible nutrients cocoanut cake produced no better results than the residues from palm oil manufacture. The palm-nut cake obtained by pressure had the same influence as the palm-nut meal obtained by extraction.

Experiments on feeding dairy cows, C. B. Jones (*Abs. in Dairy, 18 (1906), No. 206, p. 39*).—The feeding experiments included 20 cows and covered in all a period of 48 weeks. Some of the general conclusions reached are in substance as follows:

A heavy grain ration of 12 lbs. or more may cause an increase in the yield of milk but not always with profit. The limit beyond which it is unprofitable to increase the allowance of concentrated feeds was not ascertained, but it may be

regarded as certain that 12 lbs. per 1,000 lbs. live weight is, on the average, excessive. It is considered doubtful if an increase in the amount of grain has any appreciable influence upon the quality of the milk.

The morning milk of an average lot of cows, even when well fed, may frequently be under the standard in butter fat during the earlier part of the lactation period and an increased amount of grain causes but little improvement in this respect. The gain in live weight of cows fed a heavy grain ration was much greater toward the end of the lactation period. The results, therefore, are in favor of the practice of feeding dairy cows grain rations largely in proportion to the amount of milk produced.

The second series of experiments reported related to the effect upon the quantity and quality of milk of equal and unequal intervals between milkings. One lot of 5 cows was milked at 6 a. m. and 4 p. m. and another lot at 6 a. m. and 6 p. m. When the intervals were equal the morning milk contained on an average 4 per cent of fat and when unequal 3.6 per cent, confirming results obtained elsewhere.

Contribution to the manner of conducting practical feeding experiments with milch cows, A. OSTERMAYER (*Österr. Molk. Ztg., 13 (1906), Nos. 2, pp. 15–17; 3, pp. 29, 30*).—This article summarizes briefly the results of 15 feeding experiments in different parts of Moravia. Each test lasted 120 days divided into 5 periods. During the second and fourth periods the value of sesame cake was tested. In all 93 cows were used in the trials. The results were favorable to the feeding of sesame cake, but are discussed mainly with a view to showing the value of conducting practical tests of this kind.

On the influence of feeding stuffs on milk and milk products, A. BURR (*Molk. Ztg., 19 (1905), Nos. 40, pp. 1025, 1026; 45, pp. 1147, 1148; 49, pp. 1243, 1244; 50, pp. 1267, 1268; 51, pp. 1295–1297*).—This summarizes considerable information on the effects of feeding cows potatoes, potato vines, potato pulp, the residue from the manufacture of alcohol from potatoes, root crops, beet pulp, molasses, artichokes, various leguminous crops, and other feeding stuffs.

Dairy cow demonstration of the Louisiana Purchase Exposition, E. H. FARRINGTON (*Fort Atkinson, Wis.: W. D. Hoard Co., 1905, pp. 64, figs. 25*).—This report contains the supplementary regulations governing the tests, the general plan on which the demonstration was conducted, analyses of the feeding stuffs used, and the daily records of the herds, which consisted of 5 Brown Swiss cows, 15 Holstein cows, 25 Jersey cows, and 29 Shorthorn cows. The test lasted 120 days. The following table summarizes some of the data obtained:

Record of the best, poorest, and average cow in each herd.

	Daily yield of milk.	Fat content of milk.	Daily yield of fat.	Daily yield of butter.	Daily yield of solids-not-fat.	Food cost of milk per quart.	Food cost of butter per pound.
Brown Swiss:	*Lbs.*	*P. ct.*	*Lbs.*	*Lbs.*	*Lbs.*	*Cts.*	*Cts.*
Best cow	51.0	3.40	1.748	2.042	4.363	1.09	13.6
Poorest cow	38.5	3.80	1.477	1.731	3.585	1.39	15.5
Average cow	44.2	3.62	1.596	1.870	3.919	1.24	14.7
Holstein:							
Best cow	67.5	3.50	2.355	2.753	5.171	.90	11.0
Poorest cow	47.1	3.20	1.507	1.756	3.614	1.22	16.4
Average cow	53.4	3.43	1.832	2.120	4.239	1.07	13.5
Jersey:							
Best cow	48.4	4.80	2.334	2.750	4.357	1.10	9.7
Poorest cow	38.8	4.10	1.615	1.898	3.441	1.30	13.2
Average cow	41.5	4.70	1.936	2.280	3.634	1.16	10.5
Shorthorn:							
Best cow	43.4	4.00	1.737	2.037	3.720	1.09	11.7
Poorest cow	21.4	3.90	.843	.988	1.902	2.15	23.4
Average cow	34.6	3.80	1.277	1.495	2.980	1.32	15.3

Official tests of dairy cows, 1904–5, F. W. Woll (*Wisconsin Sta. Bul. 131, pp. 46, figs. 20*).—During the year 864 tests were made of 356 cows of which 245 were Holstein, 93 Guernsey, 9 Jersey, 7 grades, 1 Shorthorn, and 1 Red Poll. The tests are reported in detail and illustrations are given of many of the cows. The rules regarding the conduct of the dairy tests are appended.

Report of the professor of dairy husbandry, H. H. Dean (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 106–133*).—Brief notes are given on the work of the dairy department during the year, and experiments in butter making, cheese making, and feeding cows are reported.

Experiments in butter making (pp. 107–115).—In 5 experiments a comparison was made of churning pasteurized sweet cream directly after adding 20 to 25 per cent of culture with similar cream ripened in the usual way after adding the same amount of culture. The results of the present experiments as well as those of the previous year (E. S. R., 17, p. 178) showed that a butter of better keeping quality was produced from the sweet cream than from the ripened cream, although the yield was not quite so great.

Experiments were conducted to determine the relative value of churning sweet cream without any culture and with the addition of 10, 20, and 30 per cent of culture. The sweet cream lots churned in less time and at lower temperature than the other lots. The loss of fat in the buttermilk decreased as the amounts of culture added increased. The slight difference in the quality of the butter from the different lots was in favor of the addition of 30 per cent of culture.

Pasteurization of milk was compared with pasteurization of cream. The results showed very little difference in the quality of the butter. As the pasteurization of cream and skim milk separately is considered more convenient, this method is recommended for creameries.

Ripe cream was pasteurized at temperatures of 130, 140, 160, and 180° F. The pasteurization made little or no difference in the acidity of the cream nor in the time required for churning. The greatest loss of fat was from cream heated to 140° and the highest yield of butter from cream pasteurized at 180°. There was apparently not much difference in the quality of the butter from the 4 lots. The author, therefore, recommends a temperature of 180 to 185° for the pasteurization of ripe cream, but considers it better, however, to pasteurize the cream when sweet.

In continuation of experiments with butter preservatives, previously noted (E. S. R., 17, p. 182), tests were made of salt, borax, boric acid, mixtures of borax and boric acid, mixtures of borax, boric acid and common salt, mixtures of a commercial preservative and common salt, and 3 commercial preservatives. The results are tabulated and lead to conclusions similar to those previously quoted. The author is not prepared at present to recommend preservatives other than common salt for butter to be used for home consumption, but considers it an advantage to use 0.25 per cent boron preservatives in unsalted butter for export.

Five experiments were made in regard to increasing the percentage of water in butter. The water content of the butter was not increased by having a stream of cold water playing upon the butter while it was being worked. In only 2 instances was there an increase in the water content as the result of washing and working at the same time.

A comparison was made of 2 combined churns, the results being practically the same for both.

Experiments in cheese making (pp. 115–126).—Rennet was compared with

pepsin for coagulating milk in cheese making. The yield of cheese was slightly greater and the quality somewhat better when rennet was used. Pepsin is not recommended as a substitute for standard rennet inasmuch as it is much more difficult to prepare for use and does not keep well when dissolved.

In continuation of experiments during the 2 previous years comparisons were made of 3½ and 6¾ oz. of rennet per 1,000 lbs. of milk. The results showed very little difference in the yield of marketable cheese or in the quality as a result of using double the ordinary amount of rennet.

Nine tests were made to compare milling curds crosswise and lengthwise, the results showing little or no difference in the two methods. Curds milled length wise lost about 0.5 per cent more in weight.

Experiments were again made with cheese containing normal and excessive amounts of moisture. The results of the experiments are considered as indicating that the average percentages of moisture, 45 at dipping and 34 in the green cheese, may be increased without injuring the quality of the cheese if ripened in cold storage at about 40° F. It is stated that a rapid method of ascertaining approximately the amount of moisture in curd at dipping has been discovered, but that experiments will be conducted for another season before the results are reported.

In 18 experiments curds were heated at temperatures ranging from 101 to 110° as compared with the temperature of 98 to 100° ordinarily employed. Cooking at temperatures above 100° tended to check the development of acid, decreased the yield of cheese, and did not improve the quality.

In 16 experiments the effect of different degrees of acidity of curds at the time of salting was studied. The results showed that the greater the amount of acidity at the time of salting the less was the yield of cheese. The quality of the cheese, however, was apparently more satisfactory when the acidity was comparatively high, less than 1 per cent showing a tendency toward a poorer quality of cheese.

In 16 experiments further comparative tests were made of ripening cheese at different temperatures. The conclusion is drawn from the results obtained during the 3 years that the lower the uniform temperature at which cheese can be ripened economically, the better will be the quality of the cheese, and the less the loss in weight during ripening.

Further experiments were also made on moving cheese from the ordinary curing room to cold storage at the end of 1 week. Very little difference was observed in the quality of the cheese whether placed directly in cold storage or removed to cold storage at the end of 1 week. The conclusion is therefore drawn that cheese may be moved once a week to cold storage without interfering with the quality of the cheese, although the shrinkage will be greater.

Comparative tests for the third year were made on placing cheese on shelves and boxing directly from the press. The results agree with the previous experiments and indicate, according to the author, that it is quite practicable to put cheese into a clean, dry box and place in cold storage at 40°. The development of mold is considered an objection to the method. Boxing directly from the press reduces the loss from shrinkage.

Experiments in paraffining cheese showed that this method decreased the loss in weight but also lowered the quality of the cheese. It is considered doubtful if paraffining cheese is advisable for the ordinary cheese maker.

Experiments in dairy stable (pp. 126–131).—In tests with 4 calves a comparison was made of bran, oats, and oil cake with bran and Blatchford calf meal with and without skim milk. The conclusion is drawn from the results of

the experiments that thrifty calves for the dairy may be reared on skim milk, wheat bran, ground oats, and a little oil cake or flaxseed meal, after getting a start for about 3 weeks on whole milk.

Comparative tests were made of daily rations of 4, 8, and 12 lbs. of a grain mixture consisting of bran 4 parts, oats 3 parts, and oil cake 1 part. The fat content of the milk was practically the same in each instance. The highest daily yield per cow was from the largest amount of grain, but the average cost per 100 lbs. of milk was 68.1 cts. as compared with 51.4 and 45.4 cts. for the rations containing 8 and 4 lbs. of grain, respectively. It is believed that about 8 lbs. per day is the proper amount for average cows.

A test was made of a commercial feeding stuff designated sugar and flaxseed meal. The addition of 1½ lbs. of this material to the regular ration did not increase the yield of milk.

Dairy herd record (pp. 131–133).—Records are given of a dairy herd of 24 cows for 1 year. The yield of individual cows ranged from 10,249 lbs. of milk to 3,310 lbs. and the profit on milk over cost of food from $117.78 to $34.84.

The milk scales, the milk sheet, and the Babcock test for the farmers of South Carolina, B. H. RAWL (*South Carolina Sta. Bul. 95, pp. 17, figs. 12*).—This bulletin describes and illustrates methods of obtaining and keeping dairy herd records.

The chemical composition of colostrum with especial reference to the proteids, E. WINTERSTEIN and E. STRICKLER (*Ztschr. Physiol. Chem., 47 (1906), No. 1, pp. 58–82*).—Methods of analysis are described and references are made to the more important contributions to the literature of this subject.

From the proteids of colostrum coagulated by heat the authors obtained by hydrolysis, alanin, aminovalerianic acid, leucin, pyrrolidin-carboxylic acid, serin, phenylalanin, tyrosin, aspartic acid, glutaminic acid, cystin, and other unidentified amino acids, arginin, histidin, lysin, tryptophan, and ammonia. These proteid substances contain, in addition, one or more carbohydrate radicals.

Colostrum was found to contain the following constituents: Casein, albumin, globulin, fat, free-fatty acids, lecithin, cholesterin, glycerol-phosphoric acid, milk sugar, and urea. The following were not found: Tyrosin, cholin, nuclein, and hexon bases. Aside from milk sugar, no other optically active carbohydrate capable of reducing Fehling's solution was found.

Taint in milk due to contamination by copper, J. GOLDING and E. FEILMANN (*Jour. Soc. Chem. Indus., 24 (1905), No. 24, pp. 1285, 1286, fig. 1*).—A bad flavor in milk was traced to the use of a cooler from which much of the tin was worn off, exposing the copper.

This suggested an investigation to determine the action of milk on copper in which it was found that milk is capable of dissolving from 1 to over 100 parts of copper per million of milk. The quantity of copper passing into solution was much greater when the milk was exposed to the air. The taint originally observed in milk was reproduced experimentally in milk exposed to the influence of copper. A peculiar flavor developed in 16 to 18 hours after such contamination.

A bacteriological study was made of milk in which the characteristic flavor was present. The presence of copper was found especially unfavorable to the development of lactic-acid bacteria, and therefore tended to delay the souring of the milk. When, however, milk was heavily inoculated with lactic-acid bacteria, the milk soured without the development of the peculiar flavor mentioned. The origin of this flavor is attributed in part to the development of bacteria as influenced by the presence of copper and in part to a direct influence of the copper.

Fat content of separator slime, P. GORDAN (*Milchw. Zentbl., 1 (1905), No. 11, p. 499*).—A microscopical examination of separator slime showed the presence of large numbers of fat globules. Determinations by the Gerber method showed the presence of 10 to 19 gm. of fat per kilogram of separator slime.

Milk and butter preservatives, R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 31 (1905), pp. 69, 70*).—In 29 samples of commercial preservatives examined, sodium chlorid and sodium bicarbonate were almost invariably present in large quantities, the amount of common salt being often over 20 per cent. The boron compounds regularly present were not determined.

Investigations on the preservation of milk samples, M. SIEGFELD (*Milchw. Zentbl., 1 (1905), No. 11, pp. 488–493*).—Comparative tests were made of formalin and potassium bichromate. The results were interpreted as showing that formalin is the most satisfactory preservative for this purpose. The author recommends the addition of only 2 to 3 drops of the commercial solution diluted one-half with water to 100 cc. of milk.

The adulteration of butter, C. SIMMONDS (*Nature [London], 73 (1906), No. 1898, pp. 466–468*).—This is a concise presentation of modern methods employed in the adulteration of butter and of the means adopted or suggested for the prevention of this fraud.

Some of the factors that control the water content of butter, F. T. SHUTT, C. F. WHITLEY, and A. T. CHARRON (*Canada Dept. Agr., Dairy Comr. Branch Bul. 8, pp. 10*).—The factors studied experimentally were the temperature of churning, temperature of wash water, size of granules when churning was stopped, length of time between salting and final working, and the effects of varying amounts of salt.

From the comparison of high and low churning temperatures and high and low temperatures of wash water it was concluded that the higher the churning temperature, within reasonable limits, the higher the water content of the butter; that the higher water content, due to a higher churning temperature, may be reduced to a certain extent though not to a safe amount by a low temperature wash water; and that a high churning temperature causes a greater loss of fat in the buttermilk.

Butter was churned to the size of clover seed, corn grains, and walnuts, the results showing that the larger the granules the higher the water content of the butter. Butter worked 24 hours after salting contained 11.78 per cent of water as compared with 13.42 per cent in butter worked 2 hours after salting. Butter salted at once and worked after 24 hours contained 11.91 per cent of water, while butter worked slightly immediately after churning, and salted and worked after 24 hours contained 12.51 per cent of water. These results show, therefore, that the length of time between salting and working is an important factor in reducing the water content of butter. Allowing butter to drip for 10, 15, or 30 minutes did not materially affect the water content.

Butter salted at the rate of ½ oz. per pound and worked 2 hours after salting contains slightly more water than butter salted at the rate of 1 oz. per pound and worked after the same interval. There was practically no difference, however, when the 2 lots were worked 24 hours after salting. Butter not salted contained slightly more water than butter salted at the rate of 1 oz. per pound. A slight working of butter before salting did not appear to affect materially the water content of the butter. The results on the whole show that there is a very distinct relation between the process of manufacture and the water content of the butter.

The constituents of Emmenthal cheese, E. WINTERSTEIN and W. BISSEGGER (*Ztschr. Physiol. Chem., 47 (1906), No. 1, pp. 28–57*).—Reference is made to previous investigations on the nitrogenous constituents of Emmenthal cheese

(E. S. R., 16, p. 196), methods of quantitative analysis used are described in detail and the results obtained are reported. The following table shows the nitrogenous constituents calculated to fat, ash, and water-free substance:

Nitrogenous constituents in Emmenthal cheese.

	Age of cheese.	
	8 months.	11 months.
	Per cent.	*Per cent.*
Total nitrogen	14.48	14.73
Total proteid nitrogen	11.57	11.57
Nitrogen in coagulable proteids	.45	.28
Nitrogen in peptones	1.04	.82
Nitrogen in bases[a]	1.13	1.07
Nitrogen in lysin	.56	.47
Nitrogen in ammonia	.06	.48
Nitrogen in amino acids	1.50	1.74
Nitrogen in purin bases	.03	.03
Nitrogen in water extract	4.32	4.28
Nitrogen in phosphotungstic precipitate from water extract		2.25
Water soluble organic material	22.76	26.02

[a] Nitrogen in the precipitate by phosphotungstic acid including, in addition to the bases, lysin, tetramothylendiamin, pentamethylendiamin, other decomposition products, and cholin

On the presence of acid and rennet producing bacteria in ripening cheese, C. Gorini (*Milchw. Zentbl., 1 (1905), No. 11, pp. 494–498*).—Notes are given on the different types of bacteria capable of producing acid and rennet in cheese. These include different forms of cocci and a spore-forming bacillus designated *Bacillus acidificans presamigenes casei.* Three groups of milk bacteria are recognized—lactic-acid bacteria, which produce acid without peptonizing the casein; bacteria which peptonize casein without producing acid, and bacteria which decompose both the milk sugar and the casein.

On the classification of the bacteria of milk with special reference to the acid and rennet producing bacteria, A. Rodella (*Milchw. Zentbl., 2 (1906), No. 1, pp. 8–12*).—This is a discussion of the classification of milk bacteria.

The causes of "blowing" in tins of condensed milk, G. H. Pethybridge (*Econ. Proc. Roy. Dublin Soc., 1 (1906), No. 7, pp. 306–320*).—The author investigated the occasional occurrence of spoiled cans of condensed milk in the product of one factory, and found the cause to be yeasts which were not introduced into the milk with the cane sugar used and which were not inhibited in their activity by increasing concentration of the cane sugar.

The source of the yeasts was apparently the original milk supply. As the destruction of the yeasts by heat during the manufacture of condensed milk was not practicable, more careful attention was paid to the condition of the milk supply and a considerable improvement followed the rejection of dirty milk.

Annual report on the investigations and progress of the manufacture of sugar, J. Bock (*Jahresber. Zuckerfabrik. [Stammer], 44 (1904), pp. X+307, figs. 24*).—Chapter 1 of this review of the literature of sugar making for 1904 deals with the agricultural features of the industry, chapter 2 with the technology of sugar making, and chapter 3 with chemical methods and investigations. Two concluding chapters contain a list of patents relating to the sugar industry and statistical matter.

The manufacture of cane sirup, B. B. Ross (*Alabama College Sta. Bul. 133, pp. 143–168, figs. 2*).—The author discusses the different steps in the manufacture of cane sirup, making numerous suggestions for the improvement of methods in common use in the State. Some experimental work is also reported.

Extraction tests showed that in most cases the 2-roller and 3-roller mills

removed from 55 to 60 per cent of the juice. The highest extraction, approximately 75 per cent, was secured with a 5-roller mill. In an earlier bulletin of the station a form of sulphuring apparatus was described (E. S. R., 7, p. 719). In the present bulletin a still simpler form improvised from a large sirup barrel is described. The station has also found it possible to employ liquified sulphurous acid as a clarifying agent. While good results may be obtained by the use of sulphur fumes alone it was found that better results could be obtained by the use of lime in addition.

Instead of either of these methods, however, the bisulphite of lime may be used in the proportion of 1:200, although the sirup is not usually so bright as when the juice is treated with sulphur fumes. It is stated that in many cases the acid phosphate of lime was used as a clarifying agent with excellent results. Fairly good results were obtained by the use of sand filters for the removal of suspended matter. The use of cotton batting as a filter for the hot sirup was tested, favorable results being secured. Numerous other features connected with the manufacture of cane sirup were also studied experimentally.

Experiments with fermentation of fruit juices, G. KNUDSEN (*Tidsskr. Norske Landbr., 12 (1905), No. 5, pp. 222–230*).—Experiments with 10 kinds of pure-culture yeast of different origin in making wine from currant, raspberry, and blueberry juice are reported.—F. W. WOLL.

Chemical processes in wine making, K. WINDISCH (*Die chemischen Vorgänge beim Werden des Weines. Plieningen: Friedrich Find, 1905, pp. 122*).—This deals with the different kinds of sugar and acids in grape juice and cider, and the chemical changes taking place in these products during fermentation and storage.

The spinning and twisting of long vegetable fibers, H. R. CARTER (*London: Charles Griffin & Co., Ltd.; Philadelphia: J. B. Lippincott Co., 1904, pp. XVI+360, pls. 10, figs. 151*).—This book is a practical manual of the most modern methods as applied to the hackling, carding, preparing, spinning, and twisting of flax, hemp, jute, tow, and ramie.

VETERINARY MEDICINE.

Division of veterinary science, J. A. GILRUTH (*New Zeal. Dept. Agr. Ann. Rpt., 13 (1905), pp. 152–227, figs. 3*).—A detailed report is made of the veterinary staff of New Zealand, the work performed in meat inspection in connection with abattoirs and export slaughter houses, dairy inspection, and various investigations relating to animal diseases.

Contagious mammitis has spread without much control since the author's previous report. It is recommended that compulsory notification be required for this disease together with the registration of all dairy herds, their periodic inspection, and the sterilization and pasteurization of all milk at creameries. The present distribution of the disease is briefly outlined. In treating mammitis the author recommends injections of boracic acid. Notes are also given on the present occurrence of blackleg in New Zealand. By means of preventive vaccination the mortality of this disease has been reduced to the extent of 75 per cent.

A brief account is also given of anthrax, hepatic cirrhosis, tuberculosis, abortion, sterility, contagious pleuro-pneumonia in lambs, a disease resembling braxy, cystic kidney in pigs, cancer of the eyelid and liver in fowls, hydatids in sheep, tetanus, various forms of cancer in calves, and pasteurellosis in calves and pigs. A study of the last-named disease showed that the cause was a micro-organism belonging to the Pasteurella group, which produces a hemorrhagic septicemia. The organism appears to gain entrance through the navel

of new-born calves and other animals. Subcutaneous inoculation of the micro-organism even in large doses in calves produced only local inflammatory swellings with no constitutional disturbance. Pigs fed and inoculated subcutaneously with the cultures failed to develop any pronounced symptoms of the disease, while intravenous inoculation caused acute constitutional symptoms with high temperature.

Reports of inspectors of stock for the year ended March 31, 1905, E. CLIFTON ET AL. (*New Zeal. Dept. Agr. Ann. Rpt., 13 (1905), pp. 92–126*).—Notes are given on the number of domestic animals in various inspection districts of New Zealand and also on the state of the health of animals, with particular reference to the more important diseases, especially contagious abortion, mammitis, sheep scab, tuberculosis, etc.

Diseases of the bone and phosphates in the feed, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 9 (1905), No. 23, pp. 726, 727*).—Attention is called to the variation in the content of phosphoric acid in various food materials and to the relationship between weakness and disease of the bone and the relative scarcity of phosphoric acid in the food. In general the results of various investigators indicate that the weak condition of the bones of domesticated animals may frequently be attributed to a lack of phosphoric acid in their food.

Comparative study of different forms of tuberculosis, S. ARLOING (*Jour. Méd. Vét. et Zootech., 56 (1905), Dec., pp. 705–721*).—This article is a report presented by the author at the recent International Congress of Tuberculosis in Paris, and the report is accompanied by short statements by Kossel and Ravenel.

The author, on the basis of his investigations, has been led to the conclusion that the differences between various races of tubercle bacilli coming from different animals and man are slight as compared with their points of resemblance. This variation is, therefore, looked upon as a mere biological function of the tubercle bacillus. The various types of tubercle bacilli recognized by different bacteriologists are considered as varieties of the same species. As an argument in favor of this position, the author states that all varieties of tubercle bacilli are agglutinated by serum from tuberculous animals or human beings.

It is concluded, therefore, that human and bovine tuberculosis are of the same nature and intertransmissible. It is necessary to protect human beings from infection through tuberculous meat and milk, and also to protect animals from human tuberculous patients. Kossel, in his report, calls attention to the differences between the human and bovine type of tubercle bacillus and maintains that bovine tuberculosis is due exclusively to the bovine form of the bacillus. Pigs are susceptible to both forms, and man may become infected by tuberculous meat, but more frequently by the milk of tuberculous cows. Ravenel states that the bovine tubercle bacillus may gain entrance to man and cause tuberculous lesions. In general, the human bacillus is much less virulent than the bovine form.

Studies on tuberculosis, II, A. KÖPPEN (*Ztschr. Hyg. u. Infectionskrank., 52 (1905), No. 1, pp. 111–128*).—The literature relating to the various toxins obtained from the tubercle bacillus is briefly reviewed in connection with a bibliography. The peculiar growth of tubercle bacilli on bouillon is described and is attributed to the fact that the bacteria acquire an abundance of nutriment for their rapid growth, and, therefore, the layer of the organisms shows folds when it reaches the sides of the test tubes.

A struggle with tuberculosis in domestic animals, E. UJHELYI (*Jour. Compar. Path. and Ther., 18 (1905), No. 4, pp. 299–311*).—In Hungary, tuberculosis is said to be comparatively rare in horses, sheep, and hogs.

Statistics based on slaughter findings in 1902 showed that the number of tuberculous hogs was about 2.2 per cent. Among cattle, however, the disease prevails extensively. The conditions in Hungary seem to make it desirable to apply Bang's method in the eradication of the disease, and satisfactory results have been obtained from the use of this method on a number of estates. Statistics are given showing the distribution of the disease on these estates.

Von Behring's method of immunization of young cattle against tuberculosis, C. Guérin (*Presse Méd.* [*Paris*], *1906, No. 2, pp. 13, 14*).—The author reviews experiments thus far carried out with von Behring's method of vaccination by various investigators, including Schlegel, Eber, Lorenz, Vallée, Klimmer, Römer, Ruppel, Pearson, Arloing, et al. It appears from a comparison of the results obtained by these different investigators that von Behring's method is not dangerous to young cattle and that an effective immunity is thereby brought about. This immunity has been tested by subjecting the animal to exposure much more severe than would ever occur under natural conditions.

The properties of local toxins of the tubercle bacillus, P. Armand-Delille and Huet (*Compt. Rend. Soc. Biol.* [*Paris*], *59* (*1905*), *No. 37, pp. 656–658*).—A study of local toxins produced by the tubercle bacillus indicated that such toxins in rabbits and guinea pigs did not produce an elevation of temperature greater that 0.1 to 0.5° C. Such toxins inoculated into newborn animals also failed to produce a greater elevation of temperature.

Acid-resisting properties of fatty acids in tubercle bacilli, J. Camus and P. Pagniez (*Compt. Rend. Soc. Biol.* [*Paris*], *59* (*1905*), *No. 38, pp. 701–704*).—The authors made extensive experiments in testing the effect upon tubercle bacilli of the removal of their content of fatty acids. It was found that tubercle bacilli thus treated lost the power of resisting acids.

Experimental transmission of tuberculosis to anthropoid apes, von Dungern (*München. Med. Wchnschr.*, *53* (*1906*), *No. 1, pp. 4–7*).—A brief review is presented of the literature relating to this subject.

A number of gibbons were captured and inoculated with tubercle bacilli of human and bovine origin in doses of 0.01 gm. subcutaneously. Among the apes used in the experiment, five inoculated with bovine bacilli died within 35 to 65 days and three which received human tubercle bacilli died within 37 to 63 days. No difference whatever was observed in the action of the bovine and human tubercle bacilli. Comparative feeding experiments with gibbons also failed to show any difference between the two kinds of tubercle bacilli, since cases of generalized tuberculosis developed after feeding on either kind of the bacillus.

Tuberculous spondylitis in cows, O. Stenström (*Ztschr. Tiermed.*, *10* (*1906*), *No. 1–2, pp. 133–137, figs. 3*).—Recently several cases have been reported of this form of tuberculosis in cattle. The author describes the symptoms as observed in a few instances together with notes on the pathological anatomy.

Milk fever, its causes, symptoms, and successful treatment, J. Spencer (*Virginia Sta. Bul. 158, pp. 67–79, figs. 2*).—The author discusses briefly the symptoms, causes, and treatment of this disease.

The most effective treatment thus far discovered consists in pumping atmospheric air into the udder until this organ is tightly distended. This method has been successfully used at the Virginia Station, and a suitable apparatus for this purpose is described and illustrated. Detailed clinical notes are given on 4 cases, in 3 of which a complete recovery took place, while in the fourth case the treatment was not begun until the disease had progressed too far.

In order to prevent the development of milk fever, the author recommends that dairy cows should be compelled to take considerable exercise immediately

before calving, and that purgatives be given—for example, Epsom salts in doses of 1½ lbs. Attention is also called to the desirability of using antiseptic precautions in pumping the air into the udder, since otherwise an infection may take place and lead to serious inflammation.

Parturient paresis, puerperal septicemia, and paralysis after parturition, E. HESS (*Schweiz. Arch. Tierheilk., 47 (1905), No. 6, pp. 277–304*).—The symptoms of numerous cases of these diseases are given, together with clinical notes, and an account of the line of treatment adopted by the author.

In several instances transition stages were noted between the three diseases so that all three appeared to be quite closely related. The author discusses the etiology of these diseases in some detail, as based on a study of the symptoms and pathological anatomy. As is generally known, some veterinarians recommend that in order to prevent the occurrence of parturient paresis, cows should be milked during the last 8 or 10 days before parturition. Similar results are obtained from bloodletting and from the administration of laxatives. All three of the diseases may be successfully combated by the use of air or oxygen pumped into the udder until this organ is tensely distended. Puerpural septicemia, however, may require in addition to the oxygen treatment a thorough irrigation of the reproductive organs with antiseptics.

The author suggests the desirability of determining the volume and weight of the udder of cows affected with parturient paresis before and after treatment, also the amount of blood forced out of the udder by the oxygen treatment, and the variations in the abdominal blood pressure in cows before and after parturition.

The treatment of appearance of blood or hemoglobin in the milk, K. MEUCH (*Berlin. Tierärztl. Wchnschr., 1906, No. 1, p. 4*).—In two instances the author had complete success in such cases after other remedies had failed by the use of air infusion. The air pressure produced in the udder seemed to have the effect of closing the ruptured blood vessels from which the blood escaped, and thus prevented the further admixture of blood in the milk.

Infectious vaginal catarrh of cattle, THOMS (*Monatsh. Prakt. Tierheilk., 17 (1906), No. 5–6, pp. 193–211, pls. 2, fig. 1*).—The literature of this subject is critically reviewed. It appears that cattle of all ages are susceptible to infec tious vaginal catarrh. The characteristic discharge of the disease always contains numerous diplococci and streptococci. The mucous membrane of the vagina exhibits tubercles within 4 or 5 days after the appearance of the disease. These follicular enlargements gradually decrease in size after the active infection has been controlled. It appears, therefore, that a cure may be effected before the tubercles disappear.

Sterility in milch cows, its cause and treatment, ALBRECHTSEN (*Samvirk. Landbofor. Fyns Ber. 1904–5, pp. 136–150*).—Through the agency of various experimental unions in Denmark the author obtained quite extensive data regarding the number of milch cows which go farrow. In 1902 there were 180 such cows in 2,508, or 7 per cent, while the number which aborted was 112, or 4½ per cent. In a total of 19,134 cows, 1,161 went farrow.

The causes of such sterility are believed by the author to be found in the reproductive organs of the cow, and are apparently to be sought in some disease which prevents the ripening of the eggs. In the majority of cases examined by the author the corpus luteum which develops during pregnancy failed to be absorbed after parturition, and so long as it is not absorbed the cow remains sterile. The operation of removing the corpus luteum from the surface of the ovary is not difficult, and in 70 to 90 per cent of cases after this was done the cow came in estrum within 3 or 4 days. The author believes that this treat-

ment in connection with suitable treatment for abortion will practically control the problem of sterility in milch cows.

Contagious abortion among cattle, A. H. Cory (*Queensland Agr. Jour., 16 (1905), No. 3, pp. 249, 250*).—A brief account is given of the cause, symptoms, treatment, and prevention of this disease. The antiseptic solutions recommended in the treatment of the disease are carbolic acid 1 : 100 parts of water or corrosive sublimate 1 : 2,000 parts.

Cowpox, Desmond (*Jour. Dept. Agr. So. Aust., 9 (1905), No. 5, pp. 328–334, figs. 4*).—This disease occurred in an extensive outbreak in a dairy which was later examined by the author. Seven cows were found to be affected in the herd. The usual antiseptic precautions are recommended in the control of the disease.

Eradication of African coast fever, C. E. Gray (*Transvaal Agr. Jour., 3 (1905), No. 12, pp. 696–699*).—Additional experiments on the life history of the brown tick, which is the main factor in the dissemination of African coast fever, indicate that it may be possible to stamp out the disease by the observance of certain precautions. If susceptible animals are kept away from infested fields for a period of 12 months they may then be allowed to graze on such ground. The explanation of this fact is that the ticks have died in the meantime. Tick starvation in connection with thorough dipping of infested cattle may lead to the eradication of the disease.

Further experiments to note how long an area remains infected with east coast fever, A. Theiler (*Transvaal Agr. Jour., 3 (1905), No. 12, pp. 700–706*).—On sheep allowed to graze with cattle infested with the brown tick, this tick was not found to occur in great numbers. The most prominent species on sheep were *Hyalomma ægyptium*, *Amblyomma hebræum*, *Rhipicephalus simus*, and *R. evertsi*.

Experiments were carried out by the author to determine the possibility of eradicating the disease from infected fields. It was found that as soon as the ticks were dead from starvation the area was no longer dangerous. Care must be exercised, however, to prevent other animals from carrying the ticks from place to place. In one instance, a brown tick was found on a wild hare.

It is recommended that as soon as the fever temperature appears in animals affected with African coast fever they be confined in inclosures so that ticks from them will be unable to get upon the pastures. The incubation period of coast fever is not more than 20 days. During this time ticks on cattle do not become virulent. It should also be remembered that the ticks do not acquire the blood parasite even after the first few days of the disease, and after the tick falls to the ground it must first undergo a moulting process before it is able to infest healthy cattle. This period lasts for not more than 20 days.

In experiments with virulent brown ticks the author was able to reproduce the disease in 8 out of 9 cases. It was also found that two ticks were sufficient to cause a development of fever.

Redwater in cattle and its treatment with Damholid, Westermann (*Berlin. Tierärztl. Wchnschr., 1905, No. 52, pp. 881, 882*).—In the early experiments carried out by the author in treating redwater with injections of Damholid, the animals all died of what appeared to be malignant edema. Later experiments, however, showed that if the inoculation was made during the early stages of the disease it always has a decidedly beneficial effect.

Good results are also obtained from the administration of 50 gm. of Damholid daily through the mouth. In most cases the treated cattle recovered entirely within 3 days. Damholid was also used in one case of advanced tuberculosis, being fed in water at the rate of 50 gm. per day. At the beginning of the treat-

ment the animal was greatly emaciated and weak, but within 4 weeks the health of the animal had greatly improved and it had apparently recovered from tuberculosis.

The cause of wooden tongue, M. P. RUKHLYADEV (*Uchen. Zap. Kazan. Vet. Inst., 22 (1905), No. 5-6, pp. 448-451*).—The literature of this subject is briefly reviewed, in connection with some experimental work of the author relating to the pathological histology of the tongue of cattle affected with actinomycosis.

A wasting disease of young cattle, L. A. KLEIN (*South Carolina Sta. Bul. 114, pp. 11*).—On 5 farms visited by the author, 72 out of 114 young cattle had been attacked by verminous gastritis. Of these animals, 44 had died, while only 2 had recovered, the others still being sick.

The parasite was found to be *Strongylus contortus*. An account is given on the history of this parasite with notes on the symptoms caused by it. The first symptoms appeared in August and September, and the deaths were most numerous in October and November. The disease appears, therefore, to be later in occurrence in the South than in the northern States. It is nearly always fatal since only 2 of the animals in question recovered, and these were nearly 2 years old.

Verminous gastritis is confined largely to young cattle under 1½ years of age. In some cases the disease occurred not only on low wet pastures but on hilly land. Excellent results were obtained from the use of coal-tar creosote given at the rate of 25 drops to 2 teaspoonfuls in a pint of water according to the age of the animals.

Cattle plague in Egypt in 1903 to 1905, W. LITTLEWOOD (*Jour. Compar. Path. and Ther., 18 (1905), No. 4, pp. 312-321*).—Apparently cattle plague was introduced into Africa during the last 20 years by the importation of cattle from Arabia. Data are presented showing the present distribution of the disease.

In outbreaks of cattle plague it is desirable to bury the carcasses of animals dead of the disease, but some difficulty has been experienced in having this done systematically. It was also necessary in some instances to close cattle markets during the progress of an outbreak. Since man is not affected by eating the meat of cattle affected with the disease, the use of such animals has served to spread the disease. The best treatment, in the author's opinion, is the use of serum wherever this material is to be conveniently obtained. Notes are also given on the use of bile and a combination of blood and serum.

Malarial catarrhal fever (blue tongue) of sheep in South Africa, J. SPREULL (*Jour. Compar. Path. and Ther., 18 (1905), No. 4, pp. 321-337, figs. 10*).—This disease has been recognized in South Africa since 1880, but its nature and etiology were not systematically studied until 1900. The lesions which occur in blue tongue are chiefly confined to the mouth and feet and are accompanied by fever.

The disease prevails extensively in Cape Colony, Bechuanaland, British Protectorate, and Transvaal. It has been observed that sheep are less susceptible to the disease when the wool is long than when it is short, and some protection is afforded when they are kept in sheds at night. Apparently, therefore, some blood-sucking insect is concerned in the spread of the disease, since infection does not take place by mere contact. The period of incubation is 2 to 5 days, and the mortality varies from 5 to 30 per cent.

The author used chlorid of potash with tannic and boric acid as a treatment for the lesions in the mouth. Rest and cool surroundings are recommended in cases of the disease. Blue tongue may sometimes be prevented from spreading further by removing the herd of sheep to another grazing ground, especially if

this be at a higher altitude. The micro-organism of the disease is believed by the author to be ultramicroscopic.

No immunity was produced by the use of bile from affected animals, and this treatment appeared to be somewhat dangerous. The results obtained from the inoculation of blood of recovered animals gave varying results. Apparently such blood gradually becomes more attenuated, and in some instances can be used with success. The disease may be transmitted by inoculation to goats and cattle.

Blue tongue in sheep, A. THEILER (*Transvaal Agr. Jour., 3 (1905), No. 12, pp. 685–696*).—This is an infectious disease attacking chiefly the mucous membranes of the mouth, nose, and intestines, and sometimes causing inflammation of the feet. The popular name is derived from the bluish discoloration of the lips, tongue, and gums.

The disease is quite similar to the so-called catarrhal fever of sheep, but is believed to be specifically distinct. It is distributed quite largely throughout the Transvaal, but does not occur every year to a serious extent. The period of incubation is 4 days and the fever temperature may rise to 107° F. The disease is fatal only in a small percentage of cases, and in these cases the mouth is the seat of the principal lesions. The lungs become edematous and minute blood spots appear under the endocardium.

The disease appears not to be transmitted by mere contact. It is, however, due to a micro-organism, as shown by the fact that the serum of the blood of affected animals is exceedingly virulent. The micro-organisms, however, appear to be ultramicroscopic. The disease can not be transmitted to horses, but may be transmitted to goats. One attack produces considerable immunity, and the serum of hyperimmunized animals may be used in vaccinating other animals to prevent the development of the disease.

Scab and its eradication, C. E. GRAY (*Transvaal Agr. Jour., 3 (1905), No. 12, pp. 669–675, pl. 1*).—Hand dressing of sheep infested with scab mite is not recommended. The formula for lime-sulphur dip as proposed by the Department of Agriculture of Cape Colony calls for 25 lbs. of sulphur and 20 lbs. of lime per 100 gal. of water. This dip and the formula recommended by the Bureau of Animal Industry of this Department are both considered effective.

Infestation of lambs with flies, O. JORDAL (*Norsk Vet. Tidsskr., 17 (1905), No. 6, pp. 121–124*).—Young lambs are frequently attacked by flies such as *Musca cæsar*, *M. sericata*, etc. The extent of this infestation in Holland, Germany, and Norway is briefly indicated. In certain cases favorable results were obtained from the use of turpentine, pyrol, or benzine.

The characterization of hog cholera group, A. BÖHME (*Ztschr. Hyg. u. Infectionskrank., 52 (1905), No. 1, pp. 97–110*).—According to the author's investigations the bacillus of psittacosis belongs with the hog cholera group as well as the true hog cholera bacillus, paratyphoid bacillus, and some of the bacteria of meat poisoning.

Among the meat-poisoning bacilli the so-called Moorseele bacillus is somewhat typical. Serum obtained from animals affected with psittacosis exercises a preventive or slightly immunizing action against all bacilli of the hog cholera group and appears to be more generally effective in this regard than the sera from other organisms belonging to the group. The psittacosis serum also agglutinates typhoid bacilli.

Heartwater and horse sickness: A new protective inoculation against horse sickness, J. M. COUTTS (*Jour. Compar. Path. and Ther., 18 (1905), No. 4, pp. 337–345*).—A report is made on 7 cases of inoculation of horses with heartwater. Heartwater and horse sickness are very similar in appearance.

Both diseases may be transmitted by inoculation, but neither is infectious. The micro-organism appears to be ultra-microscopic, both are peculiar to South Africa, and the post-mortem appearances are similar.

In the author's experience it is somewhat difficult to inoculate horses with heartwater, but when such inoculation is successful the post-mortem conditions are similar to those of horse sickness. Animals which recover from the inoculation show some immunity against horse sickness. The author recommends 4 inoculations of the blood from animals recovered from heartwater in producing immunity against horse sickness.

The identity of surra and mbori, A. LAVERAN (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 26, pp. 1204–1207*).—The results obtained by the author's investigations indicate quite clearly that trypanosomes found in cases of surra and mbori in camels and other animals belong to the same species *Trypanosoma evansi*. The forms obtained in these two diseases may be varieties of the same species, but mutually vaccinating properties are observed.

The pathological histology of experimental infection with Trypanosoma brucei, E. SAUERBECK (*Ztschr. Hyg. u. Infectionskrank., 52 (1905), No. 1, pp. 31–86, pls. 2*).—In the author's experiments with this organism it is found that with rats, guinea pigs, rabbits, and dogs infection leads to death within a few days in the case of dogs and rats, and within a few weeks or months in the case of guinea pigs and rabbits.

The trypanosomes increase regularly and constantly in number in rats and dogs, but are irregular in their occurrence in guinea pigs and rabbits. In the case of some of the experimental animals the immediate cause of death appeared to be found in excessive irritation of the brain. The trypanosomes apparently do not develop irregular forms in the blood, but only in the lymphatic glands, spleen, bone marrow, liver, and lungs. The irregular forms are the same as appear in the blood after death.

In the lymphatic glands, spleen, and bone marrow it is not the endothelial elements but the free cells which are most altered by the development of large nuclei. The cell multiplication in such structures precedes hyperemia and enlargement of the organ. The author was unable to find any parallelism between the duration of resistance to the disease and the degree of phagocytosis.

Immunization against tsetse-fly disease, C. SCHILLING (*Ztschr. Hyg. u. Infectionskrank., 52 (1905), No. 1, pp. 149–160*).—Material for the author's investigations was obtained from a horse affected with the disease and the blood parasites were transferred by numerous inoculations in gray rats and dogs. The parasites were also found in considerable numbers in cattle.

It was found during these experiments that frequently the peripheral blood of affected animals contains none of the blood parasites. Goats are very resistant to nagana. Experiments were tried in killing the blood parasites in the peritoneal exudate of affected dogs and using this material for immunization. The results, however, were not constant.

Trypanosomiasis in camels, A. THEILER (*Transvaal Agr. Jour., 3 (1905), No. 12, pp. 717–721*).—Trypanosomiasis broke out in a herd of 36 camels which were imported from Somaliland.

Blood was taken from those camels which were evidently diseased and ultimately from all the camels and used in inoculation of dogs. It was found that only two camels were free from the disease. Since later some doubt appeared regarding the health of these two animals, all of the camels were killed for the purpose of stamping out the infection. The disease in question was apparently surra or a closely related infection.

The etiology of so-called horse typhoid or petechial fever, BARUCHELLO and MORI (*Deut. Tierärztl. Wchnschr., 13 (1905), No. 51, pp. 589–592*).—The disease

in question is apparently closely related to malaria. The development of fever occurs suddenly and assumes an acute form. Death may result within 2 or 3 days.

Quite satisfactory results were obtained from the use of subcutaneous and intravenous injections of quinin. The blood parasites may be easily obtained and stained for examination. A detailed description is given of these parasites in their different developmental forms. Intravenous inoculation of blood from affected animals failed to produce the disease in horses, rabbits, and guinea pigs. Apparently the disease is transmitted by means of insects, perhaps mosquitoes.

The bacterial flora of the nasal cavity of the horse, De Angelis (*Rec. Méd. Vét., 83 (1906), No. 1, pp. 31-35*).—According to the author's investigations a staphylococcus and streptococcus are constantly found in the nasal cavity of the horse. These organisms are not pathogenic for laboratory animals, but may produce local or even generalized infection in the horse. These micro-organisms are identical with nonpathogenic forms in their morphological and pathological characters. Repeated occurrence of them in horses does not produce immunity.

The occurrence of the tetanus bacillus in animal feces, A. Hoffmann (*Hyg. Rundschau, 15 (1905), No. 24, pp. 1233-1239*).—In the author's experiments cultures were used from the feces of sheep, horses, and cattle in inoculating mice for the purpose of determining whether tetanus bacilli were contained in this material. In the 22 experiments carried out along this line, tetanus was produced in only one case. It appears, therefore, that the feces of animals which bear wounds at the time may contain tetanus bacilli in sufficient numbers to cause infection.

The destruction of rabies virus in the peritoneal cavity, P. Remlinger (*Compt. Rend. Soc. Biol. [Paris], 59 (1905), No. 38, pp. 689, 690*).—It has long been known that the virulence of pathogenic bacteria may be increased when these micro-organisms are kept in collodion sacs, or otherwise in the body cavity of susceptible animals, and also by repeated passage by means of hypodermic or intravenous inoculations through animals. When rabies virus, however, is placed in the body cavity of dogs and rabbits the opposite effect is observed.

In the author's experiments samples of virus thus treated were removed every day and used for inoculating experimental animals. It was found that none of the animals inoculated after more than 24 hours had passed was affected. The rabies virus was completely destroyed by remaining in the peritoneum for 24 hours.

The diagnostic value of Negri's corpuscles, Bohne (*Ztschr. Hyg. u. Infectionskrank., 52 (1905), No. 1, pp. 87-96, pl. 1*).—In the investigations reported in this paper the author came to the conclusion that Negri's corpuscles must be looked upon as of specific diagnostic value for rabies. If tissue from suspected animals is embedded by the quickest known methods it is possible to arrive at a positive diagnosis within a few hours. In case the result is negative it is desirable to make a test by means of animal inoculation. The exact nature of Negri's corpuscles is not certain, and in the present state of knowledge the author believes that their parasitic nature is somewhat doubtful.

The nonvirulence of milk of rabid herbivorous animals subjected to intravenous injections of rabies virus, J. Nicolas (*Jour. Méd. Vét. et Zootech., 56 (1905), Dec., pp. 721-726*).—The author's experiments were carried out on goats and cows, and the milk obtained from inoculated animals was used in the inoculation of laboratory animals.

It was found that the milk and mammary tissue of herbivorous animals suffering from rabies is never virulent. In goats and cows subjected to

repeated intravenous injections of rabies virus the milk showed no virulence. It is suggested therefore that the milk of such animals may be used without danger.

Paralysis of the lower jaw in dogs independently of rabies, DAUPHIN (*Rec. Méd. Vét., 83 (1906), No. 1, pp. 28–30*).—In several instances, the author has observed paralysis of the lower jaw in which the dog was certainly not affected with rabies. Since this symptom is depended upon to some extent in suspected cases of rabies, the observations of the author make it desirable to exercise greater precaution in reaching a diagnosis.

Esophageal spiropterosis in dogs in southern Tunis, LE MAITRE (*Rec. Méd. Vét., 83 (1906), No. 1, pp. 17–24*).—The climate of Tunis has been found to be very unfavorable for European dogs. A large proportion of them die of distemper, rabies, and a sort of malarial fever accompanied with anemia and esophageal spiropterosis, the latter being most important.

This disease is due to the presence of *Spiroptera sanguinolenta* in the esophagus of infected dogs. The author made observations on a number of cases of this disease and found that at least ⅓ terminated fatally. The disease is most prevalent in spring and summer. There appears to be an undetermined intermediate host of this parasite. It is impossible to recognize the earliest stage of infestation. As soon as the disease can be recognized it is desirable to administer emetics and anthelmintics. The author prefers turpentine for this purpose.

Internal mycoses and the micro-organisms which cause them, P. SAVOURÉ (*Arch. Par., 10 (1905), No. 1, pp. 5–70, figs. 20*).—Elaborate descriptions, with notes on their life history, are given for various species of Mucor, Rhizopus, Rhizomucor, and Aspergillus. Certain species of these genera have long been known to cause pathological lesions in animals and man.

It was found that these genera may cause the formation of tubercles in susceptible animals which are characterized by a disintegration of the tissues and sometimes of the whole organ. As a rule, susceptible animals appear to show a certain amount of resistance to the spores of these molds, due to the phagocyte action of the endothelial cells of the blood vessels.

A series of experimental inoculations were made on rabbits, during which various species of these genera were used. *Mucor racemosus* was found to be nonpathogenic. More or less serious lesions were caused by *M. corymbifer, M. regnieri, M. truchisi, Rhizopus equinus, Rhizomucor parasiticus, Aspergillus fumigatus, A. oryzæ*, and *A. sulphureus*.

Toxic substances produced by animal parasites, R. BLANCHARD (*Arch. Par., 10 (1905), No. 1, pp. 84–104*).—An elaborate study was made of animal parasites of various orders, and the author comes to the conclusion that all animals including parasites of all groups secrete toxins which exercise more or less active effects.

The parasites of the intestines, including nematodes, tapeworms, flukeworms, etc., produce toxins which are, however, eliminated by the intestines of the host without producing any serious consequences. Parasites in the blood such as Filaria, Bilharzia, etc., cause a very slight intoxication, while the toxins produced by the blood-infesting protozoa such as trypanosomes are eliminated through the kidneys.

RURAL ENGINEERING.

Reports on the irrigation service in Upper and Lower Egypt, A. L. WEBB and R. E. VERSCHOYLE (*Rpt. Pub. Works Dept. Egypt, 1905, pp. 51–169, pls. 6*).—These reports are part of a complete report upon the administration of the Public Works Department in Egypt for 1904, by Sir William Garstin, and are of

interest as showing the practical working of the elaborate English administrative system on the Nile.

They consist largely of detailed statements of expenditures, with descriptions of new work started and repairs made, and of gage-height records, showing the use made of flood and reservoir water and its distribution among the basins and canals. The duty of water is discussed, the actual duty observed running from 80 to 105 acres per cubic foot per second for general crops, twice as much water being used on rice. The season is not given in this connection, but appears to be 90 to 100 days. A report on drainage works and roads is included.

Typical examples of sewage irrigation, P. EHRENBERG (*Fühling's Landw. Ztg.*, *54* (*1905*), *No. 24*, *pp. 831–847*).—After showing the value of sewage as a fertilizer, the author points out that its continuous discharge demands constant care day and night through the year, to distribute the sewage over the land, and that in many cases it must be applied regardless of injury to the crop, since its disposal is the paramount object.

There are, however, certain plants which resist overirrigation and which are hence particularly useful here. Among field crops hemp and asparagus would be ideal plants did they not entail much hand labor and a large investment. Beets require disking and are uncertain in starting. Even corn fodder does not meet the conditions wholly and is inferior to grass (*Rieselgrass*) which is the best crop of all.

Next in importance is truck raising. The very quick-growing vegetables are grown on freshly-irrigated land, and harvested without further application of sewage. Other vegetables are hilled up to prevent actual contact with the sewage. The distance from market must be short enough so that truck may be gathered and sold the same day. Nightshade and other stubborn weeds flourish in autumn when the gardener is busiest, and cause much trouble, since mowers can not be used on account of the dikes and checks. Near Berlin are over 500 lessees of sewage-irrigated lands which aggregate nearly 4,500 acres. The annual rental in 1904 was $22 per acre.

In irrigating grass land, sewage may be applied summer and winter in great excess without injury, and the yield is phenomenal. In 1904, 22.2 tons of fresh-cut grass per acre was reported, and in 1889, 26.2 tons. Mowing machines have not come into use, the most primitive methods prevailing. Without roadways through the fields the hay must be carried out on litters.

The author includes a number of tables showing the value of sewage, rental of land, yield of crops, seed required, etc., and a discussion of fresh-cut grass as a milk producer.

Reservoirs, M. RINGELMANN (*Jour. Agr. Prat.*, *n. ser.*, *10* (*1905*), *No. 51*, *pp. 787–790*, *figs. 6*).—An elementary discussion of the design of earth dams.

Weir experiments, coefficients, and formulas, R. E. HORTON (*U. S. Geol. Survey*, *Water-Supply and Irrig. Paper No. 150*, *pp. 188*, *pls. 38*, *figs. 16*).—This paper is a compilation of the work of Francis, Fteley and Stearns, Bazin, Hamilton Smith, Thomson, Cippoletti, and others on thin-edged weirs, and the experiments of Bazin, the U. S. Board of Engineers on deep waterways, the U. S. Geological Survey at the Cornell University hydraulic laboratory, and others on weirs of irregular cross section. The coefficients of Bazin are recomputed so as to cover more general cases. Submerged weirs and weir discharge under varying heads are discussed at length.

The good roads problem in Iowa (*Iowa Engin. Sta. Bul.*, *2* (*1905*), *No. 6*, *pp. 24*, *pls. 15*, *dgms. 2*).—The work of the Iowa Highway Commission since its creation in 1904 is described, with data showing the general road situation and the funds available for improvements. Drainage and the use of the King road

drag are urged as a solution of the problem for earth roads. The annual cost of maintenance does not exceed $3 per mile. Culverts and short bridges of reinforced concrete are advised.

Although a general lack of road metal over the State is admitted, the commission states that "we believe the earth road is not a permanent solution of our road problem, so far as the main traveled roads are concerned. In every county the network of main traveled roads should in the end be made permanent hard roads, surfaced with broken stone, if possible, and at least with gravel." But it adds: "We do not advise the construction of roads which cost $5,000 to $10,000 per mile to build, and $100 per mile per year to maintain, unless for a very few very important roads. We advise, rather, the construction of such stone roads as can be built in this State and others at costs of $1,200 to $2,500 per mile, and of gravel roads such as are being built in this State for $400 to $600 per mile where the gravel is found near at hand."

The use of cement for farm purposes, S. M. WOODWARD (*Municipal Engin., 30 (1906), No. 2, pp. 99–102*).—The possible scope of concrete as a material for farm buildings, floors, approaches, fence posts, troughs, and other farm purposes is briefly outlined, and its uses in California for irrigation structures are described at more length. Cost data for ditch and reservoir linings and for cement pipe in small sizes are given.

Denaturized alcohol for farm purposes, C. J. ZINTHEO (*Gas Engine, 8 (1906), No. 1, pp. 6–9*).—A review of the possibilities in the use of alcohol made from waste farm products for heat, light, and power, showing the urgent necessity of free alcohol for industrial purposes.

Any farm product containing large percentages of starch or sugar, such as grains, potatoes, beets, and cornstalks, may be used. Distillers claim that corn at 40 cents will produce 94 per cent alcohol at 13.5 cents a gallon, and that it has been made at a cost as low as 8 cents. It has been sold for 18 cents a gallon over the tax. While its heating power is about half that of gasoline, its combustion is so much more perfect that it is about as efficient, gallon for gallon.

European governments have all removed the tax on denaturized alcohol, and large areas are devoted to crops for producing it. In America free alcohol would not only insure cheap power, but would steady the price of corn, and absorb local overproduction of other crops.

Straw as a substitute for coal, C. VOITELLIER (*Jour. Agr. Prat., n. ser., 10 (1905), No. 48, pp. 686–688*).—The caloric value of straw is less than one-fourth that of coal, and this fact, added to the difficulty of firing with straw, makes it a poor fuel for steam boilers. The writer states, however, that when made into producer gas and used in a gas engine, 1 kg. of straw will yield as much power as 3 or 4 kg. of coal used to produce steam. Compared with coal at 40 francs per ton, the power value of straw on this basis would be 150 francs per ton, or something like $35 per acre for an average yield. The straw should be baled, and for the sake of economy power plants should be concentrated in 70 to 100 horsepower units.

The capacity of wind motors, M. RINGELMANN (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 18, pp. 688, 689*).—The experiments recorded were made on a 12-ft. mill with wooden vanes, and bear out former tests in showing that with a constant load the rate of work varies as the first power of the wind velocity. An analytical explanation of the reduced efficiency at higher velocities is offered, which shows that the effective area presented to the wind tends to diminish as the ratio of wheel rate to wind velocity increases. The method of determining the most effective load for a particular locality from daily wind records is given.

A note by M. Ringelmann on the same experiments is found in *Jour. Agr. Prat.*, n. ser., 10 (1905), No. 48, pp. 686–688.

New farm machinery, B. MARTINY (*Fühling's Landw. Ztg.*, *55* (*1906*), *No. 2*, *pp. 68–72*, *figs. 3*).—Two straw cutters are described, one having a number of star-shaped knives on the same shaft, which project upward through slits in the bottom of a long hopper when the shaft revolves. The other has two heavy knives which revolve on one spindle and alternately cut the straw fed through an ordinary chute.

Lucerne cultivators (*Agr. Jour. Cape Good Hope*, *28* (*1906*), *No. 1*, *pp. 49–51*, *figs. 4*).—Three types of cultivators for alfalfa are described. One is provided with rotary pickers mounted on a large pair of wheels, and is intended for irrigated land; another is the common wheel cultivator, with special lucerne teeth; the third consists of a heavy spiked roller.

Practical cold storage, M. COOPER (*Chicago: Nickerson & Collins Co.*, *1905*, *pp. 576*, *figs. 213*).—As stated in the preface, "this book is intended to cover the field of applied refrigeration with the exception of ice making, ice machines, and the technical and theoretical side of the mechanical production of refrigeration," and is a comprehensive treatise on the construction and management of cold-storage plants of all kinds.

The four objects of refrigeration are stated to be to prevent the premature decay of perishable products, to lengthen the period of consumption and thus greatly increase production, to enable the owner to market his products at will, and to make possible transportation in good condition from point of production to point of consumption irrespective of distance. The author takes up in detail the subjects of insulation, air circulation, ventilation, and the control of humidity in plants using artificial methods of refrigeration. He next deals with the storage of particular products in order of their importance, including eggs, butter, cheese, general creamery and dairy refrigeration, fruit, fish, fabrics, and furs.

The shipping of meat and other perishable products, and ice refrigeration in general are thoroughly treated, and methods of harvesting, handling, and storing ice, and approved methods of building ice houses of all sizes are fully described. The book is full of figures and drawings showing details of construction. A number of tables are included, showing the relative insulating qualities of various materials, etc., and a table of cold storage and freezing temperatures for various products is appended.

The extremely recent development of refrigeration is shown by the statement that scarcely any of the printed matter published earlier than 1895 was found of use in writing this book. The cold storage of furs and fabrics is a recent development which is likely to prove an important use of refrigeration.

AGRICULTURAL EDUCATION.

Annual report on the distribution of grants for agricultural education and research (*Bd. Agr. and Fisheries* [*London*], *Ann. Rpt. Agr. Ed. and Research*, *1904–5*, *pp. X + 209*).—This consists of a general report on the work of the year, a list of grants awarded in 1904–5, and 4 appendixes: (1) Reports on institutions receiving grants, (2) education in rural districts—school gardens, (3) summary of the agricultural instruction provided by county councils in England and Wales in the year 1904–5, and (4) statement showing the expenditure of county councils in England and Wales upon agricultural instruction in the years 1903–4 and 1904–5.

In the general report attention is called to an increase of $4,856 in the amount given to local institutions in aid of agricultural education. One-half of this sum

was awarded in two equal grants for lectureships in forestry at the University College of North Wales, Bangor, and Armstrong College, Newcastle-upon-Tyne. The sum of $971.20 was given to aid "the excellent scheme of instruction provided by the County Council of Essex at their technical laboratories in Chelmsford," and $971.20 and $485.60, respectively, to the agricultural departments of the university colleges of Reading and Aberystwyth on account of the establishment of farms in connection with these institutions.

The statement is made that the principal reason for giving financial assistance to educational institutions was to provide facilities for training young men for the practice of agriculture, but it is considered noteworthy that a large percentage of "the best students have been attracted from the practice of agriculture by the offer of research and teaching appointments, and are now filling many of the more important chairs and lectureships" in England, as well as important positions requiring trained specialists in the colonies of Great Britain and other parts of the world. It is recognized that "agricultural science offers to our best students a career which is certainly not less attractive than that presented by the older and more conventional professions."

A feature of the work of the different colleges, aided by the board during the past year, has been the attention given to the training of teachers for the elementary schools. Short courses, usually extending over 2 weeks, have been given for teachers at many of these institutions. In this work the county councils have frequently cooperated. The courses have included instruction in nature study, horticulture, economic entomology, dairying, school gardening, and other subjects of this nature. The attendance of teachers at Reading University College was 25; at Wye College, 67; at the University College of Wales, 42; at the Midland Agricultural and Dairy Institute, 61; at Harper-Adams College, 13; and at the Essex County Technical Laboratories, 30.

In the appendix on "Education in Rural District—School Gardens," detailed information is compiled from replies to 33 questions sent by the Board of Agriculture and Fisheries to the different county councils. These questions and answers relate to gardens connected with both day and evening schools and to the sources from which land, funds, seeds, and tools are supplied; the total area in gardens and the size of each plat; the instructors, their training and compensation; the number and ages of children doing garden work; the time devoted to this work; systems of cropping; supervision; systems of prize giving, and disposal of products. From the replies received, it appears that at least 32 counties have gardens connected with day schools, and 22 counties maintain other gardens either connected with evening schools or worked independently by boys and young men.

In the case of the day-school gardens, it appears that in most counties land and tools, and in a few counties seeds, are provided either directly or indirectly by the county councils. The seeds are usually provided by the local school authorities. The size of the gardens ranges from $\frac{1}{8}$ to $\frac{1}{4}$ of an acre, and the size of the individual plats from 1 to 3 square rods. Custom varies as to whether each pupil shall have a separate plat or whether the land shall be worked in common. The teachers of gardening are usually the head teachers in the schools, who in many counties are required to have credentials of qualification for this work. Sometimes gardeners are employed as instructors, though this arrangement is not very satisfactory. The ages of the pupils in gardening range from 9 to 15 years, with comparatively few less than 11 years. Two hours a week is given as the general average of time devoted to gardening.

There is no general system of cropping or prize giving, and only a few counties in which the work is under the supervision of a county instructor in horticulture, though this last is considered highly desirable. The produce in some

cases becomes the property of the boys, in others it is disposed of by the school and the proceeds used for the purchase of seeds or for the benefit of the class, and in others it is taken by the teacher, though the latter practice is not commended.

The agricultural instruction provided by the different county councils is quite varied in nature. It includes aid to the agricultural departments of colleges; employment of instructors in agriculture, dairying, poultry keeping, bee keeping, and farm hygiene; the management of field experiments, experimental farms, and fruit-growing stations, and the support of classes in horseshoeing, manual training, horticulture, and school gardens, as well as the partial support of training classes for elementary teachers. Not all of the councils carry on work in all of these subjects, but each subject receives some attention in many different counties of England and Wales.

The receipts of the county councils from the Customs and Excise Act of 1890 have decreased considerably in recent years, but notwithstanding this fact the county councils were able up to last year to increase the amounts devoted to agricultural education. The total amount received in 1903–4 was $3,369,340, and of this amount $424,764 was devoted to agricultural education in 1904–5, as follows: General expenditures, $47,997; dairy instruction, $63,512; agricultural lectures, $22,940; poultry keeping, $15,272; horseshoeing and veterinary science, $13,296; bee keeping, $5,677; horticulture, $50,818; manual processes, $6,264; miscellaneous, $19,633; scholarships, $51,240; and grants to colleges and schools, $128,597.

Agricultural instruction for adults in continental countries, J. HAMILTON (*U. S. Dept. Agr., Office Expt. Stas. Bul. 163, pp. 32*).—This bulletin is intended to supplement Bulletin 155 of this Office on Agricultural Instruction for Adults in the British Empire. It includes a discussion of systems of itinerant instruction in agriculture in Austria, Belgium, Bulgaria, Denmark, France, Hungary, Italy, Netherlands, Prussia, Russia, and Sweden, together with notes on some fixed agricultural schools for adults.

Statistics of land-grant colleges and agricultural experiment stations, 1905, MARIE T. SPETHMANN (*U. S. Dept. Agr., Office Expt. Stas. Circ. 64, pp. 9*).—Abstracts of statistics to be published later in full in the Annual Report of the Office of Experiment Stations.

Negro agricultural and mechanical colleges, J. H. BLUFORD (*South. Workman, 35 (1906), No. 1, pp. 28–35, figs. 6*).—A general discussion of the origin and present status of agricultural and mechanical colleges for negroes is followed by a more detailed description of the courses of study and equipment of the Agricultural and Mechanical College for the Colored Race at Greensboro, N. C.

This institution is said to occupy a unique position among negro schools in confining all of its instruction to agriculture, the mechanic arts, the English language, and the sciences underlying the same, limiting its instruction to males who have completed grammar school work, providing a very complete equipment, and graduating an unusually large percentage of students from its agricultural course.

Teaching agriculture in the common schools, G. SEVERANCE (*Northwest Jour. Ed., 17 (1905), No. 3, pp. 6–10*).—After discussing in a general way the need of agricultural teaching in the common schools and indicating the aim of such teaching, the writer gives a list of inexpensive materials needed for illustrative purposes, and outlines 9 exercises relating to soils and cultivation.

The relation of geography to nature study in the elementary school, H. W. FAIRBANKS (*Nature Study Rev., 1 (1905), No. 5, pp. 173–188*).—In making a

comparison between geography and nature study in the elementary schools a plea is made for the more uniform and rational treatment of both subjects.

Nature study is defined and differentiated from science. Geography in the earlier years of school life is said to deal from the same standpoint with practically the same materials as nature study, and the two should not be widely differentiated during the first 4 years of school work. After that geography should begin to deal with facts beyond the experience of the pupil, while nature study should still be largely confined to the home district.

The intimate relation existing between geography and history is also pointed out, and an outline is given of a course of study in nature study, geography, and history for the elementary school. This course is developed by grades under the term nature study (modified by the adjectives institutional, industrial, biological, physical, agricultural, geographical, and historical) until the end of the fourth grade, after which nature study is outlined as one subject of study and geography and history as another.

Studies of corn and its uses, F. H. RANKIN (*Agr. Col. Ext. Univ. Ill.* [*Circ.*], *1905, May, pp. 40, figs. 8*).—This circular presents an elementary, systematic study of corn designed to aid boys and girls in acquiring a knowledge of facts and principles in agriculture to prepare them for the successful practice of some branch of farming.

Notes and outlines are given with a view of studying the corn plant as a whole, the ear in connection with the use of a score card, and different features of corn culture and characteristics of the crop by experimentation. Notes on the composition of the different parts of the corn kernel are reproduced from Illinois Station Bulletins 43, 55, and 87 (E. S. R., 8, p. 509; 11, p. 633; 15, p. 352), previously noted. A brief discussion of the commercial products of corn is also given.

Experiments with milk and butter, J. W. DECKER (*Agr. Col. Ext. Bul.* [*Ohio State Univ.*], *1* (*1906*), *No. 4, pp. 4–10, figs. 10*).—Nine simple dairy experiments suitable for elementary schools are described and fully illustrated.

An elementary study of soil, A. B. GRAHAM (*Agr. Col. Ext. Bul.* [*Ohio State Univ.*], *1* (*1906*), *No. 4, pp. 11–14, figs. 5*).—Ten simple exercises with soils are described.

Window gardening in the schoolroom, H. B. DORNER (*Purdue Univ.* [*Pamphlet*], *1905, pp. 23, figs. 10*).—This is a pamphlet prepared by a practical florist, and gives directions for the propagation and care of plants in the schoolroom. The purpose of the pamphlet is to give teachers an insight into the habits and requirements of plants which may be used both as objects for nature study and for the beautification of schoolrooms.

MISCELLANEOUS.

Annual Reports of the Department of Agriculture, 1905 (*U. S. Dept. Agr. Rpts. 1905, pp. CXXXIV+569*).—This is made up of the reports of the Secretary and heads of Bureaus. The various reports are also issued as separates.

Eighteenth Annual Report of Alabama College Station, 1905 (*Alabama College Sta. Rpt. 1905, pp. 28*).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1905, and brief reports of the director and heads of departments. The report of the horticulturist contains a list of certificates granted nurserymen.

Annual Report of Connecticut State Station, 1905 (*Connecticut State Sta. Rpt. 1905, pt. 1, pp. 1–8*).—These pages contain an announcement concerning the work of the station, a report of the board of control, and a financial statement for the year ended September 30, 1905.

Eighteenth Annual Report of New York Cornell Station, 1905 (*New York Cornell Sta. Rpt. 1905, pp. XXIX+525+46*).—This report, which is not intended for general distribution, contains the organization list of the station, reports of the director and heads of departments, a financial statement for the fiscal year ended June 30, 1905, and reprints of Bulletins 221–232 of the station on the following subjects:

Alfalfa in New York (E. S. R., 16, p. 355); record of an attempt to increase the fat in milk by means of liberal feeding (E. S. R., 16, p. 695); the grape-berry moth (E. S. R., 16, p. 681); two grape pests (E. S. R., 16, p. 681); bovine tuberculosis (E. S. R., 16, p. 1024); an apple orchard survey of Wayne County, New York—I, The apple industry (E. S. R., 17, p. 143); II, Geology (E. S. R., 17, p. 119); mushroom growing for amateurs (E. S. R., 17, p. 141); potato growing in New York (E. S. R., 17, p. 133); an apple orchard survey of Orleans County (E. S. R., 17, p. 367); quality in potatoes (E. S. R., 17, p. 358); forcing strawberries (E. S. R., 17, p. 467); notes on the forcing of tomatoes, cucumbers, and melons (E. S. R., 17, p. 463); and experiments on the influence of fertilizers upon the yield of timothy hay when grown on Dunkirk clay loam in Tompkins County, New York (E. S. R., 17, p. 461).

Director's report for 1905, W. H. JORDAN (*New York State Sta. Bul. 274, pp. 501–518*).—This is a somewhat detailed report of the work of the station during the year.

Eighteenth Annual Report of Rhode Island Station, 1905 (*Rhode Island Sta. Rpt. 1905, pp. 169–352 + VII*).—This contains the organization list of the station, a report of the director on the different lines of station work, and more detailed reports of the different divisions which are noted elsewhere, a financial statement for the fiscal year ended June 30, 1905, list of exchanges, and an index to the report and bulletins issued during the year.

The report also contains the following articles which have already been noted from other sources: The effect of postponing the ammonium-citrate treatment of the water-insoluble portion of fertilizers (E. S. R., 16, p. 322); phosphoric acid determinations by the method of ignition with magnesium nitrate and by that of digestion with acids (E. S. R., 16, p. 843); notes on the use of acetic and of oxalic acid for extracting the charred material in preparing ash (E. S. R., 17, p. 432); and the phosphoric acid removed by crops by dilute nitric acid and by ammonium hydroxid from a limed and unlimed soil receiving various phosphates (E. S. R., 17, p. 430).

Annual Report of Virginia Station, 1905 (*Virginia Sta. Rpt. 1905, pp. 36*).—This contains the organization list, a report of the director on the work of the station during the year, a financial statement for the fiscal year ended June 30, 1905, a summary of meteorological observations (see also p. 836), and departmental reports, some of which are noted elsewhere.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, vol. 7, Nos. 9, pp. 79–86; 10, pp. 87–94*).—These numbers contain brief statistical reports on the tobacco crop of 1905, by types; colonial cotton; rice production in the United States; cotton crop of the Department of Agriculture compared with the reports of the Census Bureau; crops of Russia; the corn and tomato pack in 1905; crop conditions in Europe; the cotton crop of British India; farm animals in the United States; oil seeds in British India; crops of Germany; foreign trade in the United States for 1905; the world's meat trade; demand for durum wheat; and numerous other topics.

NOTES.

Alabama College Station.—The station has concluded a feeding experiment with 50 head of steers, which was made in cooperation with the Bureau of Animal Industry of this Department. It represents the second year of this cooperation.

Colorado Station.—E. P. Taylor, assistant to the State entomologist of Illinois, has been appointed field entomologist of the station, with headquarters at Grand Junction. He will study the insects working in the orchards of that section, more especially the codling moth. O. B. Whipple, assistant horticulturist of the station, has been transferred to Grand Junction as field horticulturist to make a study of the orchard conditions of that locality and of plant diseases. A. H. Danielson, assistant agronomist, whose resignation was recently noted, is succeeded by F. Knorr, of Minnesota. E. R. Bennett, of the Connecticut Storrs Station, has been appointed field assistant for special work in potato investigations in the potato districts of northern Colorado. This work is undertaken partly with State appropriation and partly with funds raised by local subscription. The investigations on loco, carried on in cooperation between the station and this Department, will be on a more extensive scale this year than formerly. The headquarters will be at Hugo. The station will be represented by Dr. G. H. Glover, the veterinarian.

Connecticut College and Storrs Station.—The fifth annual summer school devoted to nature and country life will be held at the college July 3–27. Storrs Hall, the new brick and stone dormitory, will be ready for the use of the school.

Florida Station.—E. W. Berger, Ph. D., recently research student at Ohio State University, has been appointed entomologist to the station. N. Adams, of Jasper, has resigned as a member of the board of trustees and J. C. Baisden, of Live Oak, has been appointed to fill the vacancy. Contracts have been let for a greenhouse and seven other agricultural and horticultural buildings at the new location of the college and station at Gainesville, together with houses for the foremen of the horticultural and agricultural departments. The houses are to be completed in sixty days and the other farm buildings very soon.
that.

Iowa College and Station.—The legislature has appropriated $11,000 for the purchase of 135 acres of additional land, 80 acres of which will be used for grazing purposes and experimental work in animal husbandry, and 55 acres for orchard instruction and experimental work in forestry. An appropriation of $5,000 was made for buildings on the dairy farm, and an equal amount for the poultry plant; and $15,000 was provided for agricultural extension work, for the conduct of which it is planned to establish an extension department.

The one-fifth mill tax levy in favor of the institution was extended for a period of five years. This will provide about $125,000 a year for buildings. About $175,000 remains from the present millage tax, which will be applied on the new agricultural building, to cost $275,000. The building will be completed from the new millage tax. An appropriation of $5,000 annually was made for good roads instruction and investigation, $3,500 annually for an engineering experiment station, and $2,400 for library.

H. G. Van Pelt has been elected to the position of assistant in animal husbandry in charge of dairy stock. He will have charge of the 200-acre dairy

farm which has recently been purchased and which is now being equipped and stocked for experimental and educational work in dairy stock. This farm will be devoted exclusively to dairy and poultry work. The poultry department is being organized and will be equipped and ready for work at the opening of the next college year. W. J. Rutherford, assistant in animal husbandry, has resigned to accept a position at the new Manitoba agricultural college.

Massachusetts College and Station.—The State legislature has appropriated $75,300, in addition to the regular permanent appropriations, as follows: For erecting, heating, and equipping a building for the botanical department, $45,000; for a new barn and a new wagon house, $21,300; for a dairy building to be used simply for the handling of the farm product, $3,000; for a new piggery, $1,000; for repairs to buildings, $3,000; and for the further maintenance of the college, $2,000. The new buildings provided for, except that for the botanical department, are to replace those lost by fire. For the new barn an unexpended balance of insurance money amounting to $12,000 is also available. The permanent appropriation of the State to the college now amounts to about $57,000 annually.

Walter B. Hatch, assistant horticulturist in the station, has resigned, and Charles P. Halligan has been appointed his successor.

Kentucky Station.—Benj. R. Hart has been appointed assistant in charge of feed work.

Michigan College and Station.—Alfred R. Kohler has succeeded Albert G. Craig as instructor in horticulture in the college. Miss Dorothea Moxness has been appointed assistant chemist in the station. A farmers' institute corn special was run over the Lake Shore and Michigan Southern Railway in April. The principal topics discussed were the improvement of corn and better methods of corn culture.

Montana College and Station.—Peter Koch has retired from the executive board of the college and station, and has been succeeded by E. Broox Martin, of Bozeman. Mr. Koch will retain the position of secretary and treasurer of the board. Joseph B. Nelson, assistant agronomist of the Utah Station, has been appointed superintendent of the dry farm experiments over the State. Seven of these dry farm substations are being conducted this year, three in the northern part of the State and four in the southern part.

Nebraska College and Station.—The title of the department of agriculture has been changed to department of agronomy and the scope of this department enlarged to include instruction and experimentation in the chemistry of soils. Alvin Keyser and E. G. Montgomery have been appointed instructors in agronomy and assistant agronomists in the station. George A. Loveland, of the U. S. Weather Bureau, has been made meteorologist of the station, vice G. D. Swezey, resigned. F. G. Miller, professor of forestry in the State University, has been appointed forester of the station.

The station has entered into cooperation with the Bureau of Plant Industry of this Department to carry on spraying demonstrations in one orchard in each of six counties to determine the profit from such spraying operations. Records will be kept of the amount and quality of the fruit produced in each orchard where trees are sprayed as compared with similar trees unsprayed.

Ohio University and Station.—The legislature appropriated a total of $135,000 for the college of agriculture—$45,000 for land, $80,000 for buildings, and $10,000 for the purchase of live stock. The $80,000 for buildings will be used for a judging pavilion, a cattle barn, and a horse barn, all as separate structures.

The following appropriations for the work of the station have been made by the State for the two years, 1906 and 1907: Expenses of board of control, $1,600; bulletin publication, $10,500; special work in entomology, botany, horticulture, and chemistry, $19,000; substations for field experiments, $15,000;

general repairs, labor, and supplies, $20,000; special work in animal industry, $12,000; library equipment and care, $800; general construction, $8,000; cooperative experiments, $10,000; forestry investigations, $10,000; total, $106,900.

Porto Rico Station.—Winthrop V. Tower, a graduate of the Massachusetts Agricultural College, where he has been for the past two years pursuing post-graduate work in botany and entomology, has been appointed plant pathologist and entomologist to the station.

Rhode Island Station.—F. L. Yeaw, a graduate of Massachusetts Agricultural College, has been made assistant in chemistry in connection with the soil investigations, and J. Frank Morgan, a graduate of St. Lawrence University, assistant chemist to the station. Alton W. Richardson, of the senior class of the University of Maine, has been appointed assistant agronomist.

Washington Station.—Albert G. Craig, instructor in horticulture at the Michigan Agricultural College, has been appointed assistant horticulturist, vice D. C. Mooring, who resigned in January to accept a similar position in the Mississippi College and Station. Extensive experiments with cereals are planned for the coming year, especially with wheat, to which C. W. Lawrence will devote his entire time.

Better-Farming Special in New England.—The first attempt to introduce this form of university extension work into New England took the form of a so-called "better-farming special" train, which was run through Massachusetts, New Hampshire, and Vermont during April. The idea was fathered by an agricultural publication, which made the arrangements with the railroads, and was carried out by the colleges and stations in the three States. A week was spent in each State, the train being each week under the auspices of the college and station in which State it was running. The train consisted of four cars, which were equipped with apparatus and exhibits illustrative of farm crops, fertilizers, animal husbandry, dairying, horticulture, entomology, and forestry. One-third of each car was given up to the exhibits, the other two-thirds forming the audience room. Forty-minute stops were made at stations along the route, the first twenty minutes being devoted to two terse ten-minute talks in each car, followed by twenty minutes for viewing the exhibits and asking questions. The undertaking was pronounced a great success from start to finish. It is estimated that about 25,000 people visited the train during its course, and a large number of people were reached who had hitherto had little knowledge of the work of the colleges and stations.

Sugar Experiment Station in Peru.—The Peruvian Government has established an experiment station for sugar cane at Lima, under the auspices of the department of the interior. The station is organized under the directorship of T. F. Sedgwick, formerly of the Hawaii Station, who writes: "We already have land and a good laboratory. The work will consist in analyses of soils, fertilizers, sugar-house products, carrying on field experiments, and giving such aid to the planters as the station may be able to give."

Edinburgh and East of Scotland College of Agriculture.—The new buildings for this college were formally opened February 28 by Lord Balfour, of Burleigh. These buildings, according to *Nature*, are in Green Square, Edinburgh, and consist of well-equipped chemical, botanical, and bacteriological laboratories and lecture rooms, and class rooms for the various other subjects taught in the college. Their cost has amounted to more than $45,000.

International Association of Colonial Agronomy.—According to a note in *Nature*, it has been decided to establish an International Association of Colonial Agronomy, to promote the scientific study of the problems of colonial and tropical agriculture and of the commercial utilization of natural products. The

project took shape at a recent meeting of the French Association of Colonial Agriculture and Colonization. A provisional committee has been appointed to organize the association, with M. de Lanessan as president, and vice-presidents from Great Britain, Germany, Brazil, Italy, Mexico, Holland, Portugal, and France. The headquarters of the organization will be in Paris.

International Dairy Congress.—The Third International Dairy Congress will be held at The Hague during the month of September, 1907. The general secretary of the congress is Dr. A. J. Swaving, Lange Voorhout 88, The Hague, to whom applications for membership should be sent.

New Review of Hygiene.—The first number of the *Hygienisches Centralblatt* has been received. This is announced as a complete international review of matters pertaining to the whole field of hygiene, and is edited by Dr. Paul Sommerfeld, director of the laboratory at the Children's Hospital in Berlin, with the assistance of a large number of specialists. The first issue contains numerous abstracts of papers on drinking water, human nutrition, food materials, milk and dairy products, food inspection, and the meat industry. The abstracts are to be printed in German. The *Centralblatt* will be issued fortnightly.

Miscellaneous.—Prof. Nathaniel Southgate Shaler, dean of the Lawrence Scientific School and professor of geology at Harvard University, died April 10 at the age of 65 years. Professor Shaler had made important contributions in agricultural geology, notably upon soils and their origin.

Prof. Adolf Emmerling, director of the agricultural chemical laboratory of the experiment station at Kiel, and professor of agricultural chemistry in the university, died March 17 at the age of 64. He had devoted much study to the chemical processes within the plant, and especially the formation of albuminoids in plant tissues.

The death is announced of Georges Barba, director of the Enological Station of Nimes.

The Gardeners' Chronicle announces the death, March 20, of Count Oswald de Kerchove, chief of the directing council of the State Botanic Garden at Brussels, and the leading spirit in all public horticultural affairs in Belgium. He was also the author of a work on palms and another on orchids.

It is proposed to erect a marble bust of the late Prof. Th. von der Goltz in the agricultural academy at Bonn-Poppelsdorf, and to establish scholarships in his memory. A committee has been formed to solicit funds for the purpose.

Dr. A. J. Ewert, formerly at Birmingham, England, has been chosen professor of botany at the University of Melbourne, Australia.

The Academy of Sciences of the Institute of France has awarded the Thore prize to Prof. G. de Istvanffi, director of the Royal Central Institute of Ampelology of Hungary, on account of his investigations on the biology of the gray rot of grapes, due to *Botrytis cinerea*.

A station for testing agricultural machinery has been established at Breslau under the auspices of the chamber of agriculture of the Province of Silesia. It is under the directorship of Dr. Ernst Foerster.

The Royal Seed Breeding Institute of Wurttemberg was established at Hohenheim in December, 1905, under the directorship of Professor Fruwirth, with Dr. H. Lang as assistant.

It is announced in *Science* that about $50,000 has already been raised for the new professorship of lumbering in the Yale Forest School of the $150,000 which is sought as an endowment. In fourteen western States $44,000 was raised from sixty contributors, representing in the main corporations and firms.

O

EXPERIMENT STATION RECORD.

VOL. XVII. JUNE, 1906. No. 10.

The outlining of plans for work under the Adams Act has led to greater consideration of what should be regarded as research in agriculture. The terms "research" and "investigation" have been used freely in reference to experiment station work, and often more broadly than they are employed in science generally. We have fallen into the habit of speaking of much of the work as investigation, which in a strict sense can not be regarded as of that grade. The result has been considerable confusion in the minds of station workers, as well as the general public, as to the distinction between this and other grades of work less technical and fundamental in character.

There are several reasons which contribute to this uncertainty in the use of terms. Agriculture is a new science. Our knowledge is not as well systematized and classified, and the problems for research are not so definitely outlined as they are in the older sciences. Being a composite science, it has been built up on the basis of the pure and natural sciences. It has drawn upon these for many facts, which have been given a scientific or a practical application in agriculture. Important as this application may be, it is not always to be regarded as research or a scientific discovery. All knowledge is supposed ultimately to have a useful application, and the work of the experiment stations has done a vast deal to demonstrate this fact and to give this knowledge a tangible value.

Again, the needs of agricultural practice have frequently blinded station workers and led them to mistake for investigation tests and demonstrations or simple experiments involving no original features, but which led to an answer to the farmer's question. They have been flooded with practical questions, and have set out to answer these questions in the most direct and quickest way. Results of this kind have accumulated very fast. The workers as a rule have been too busy and too much absorbed to stop long to philosophize or speculate upon the broader and deeper scientific aspects of their work or to inquire into the reason of the results observed.

Hence it is that much of our experimental work has given results which are largely empirical. We find that if we follow a certain programme of operations we will get a given result quite constantly. Why? Usually because this result has been observed in a variety of trials; not because the underlying principles have been determined, and the relation of these to the particular problem, as for example, that a given practice is found to have a special effect on the moisture conditions or aeration of the soil, or to bring about more congenial conditions for the organic life of the soil, or to have a definite effect on the physiological activities of the plant itself. The experimenter often sees only the final result, and is satisfied with this if it is favorable. The investigator will strive to determine the cause of what he sees and the broader bearings of the results of his experiments. This will stimulate him to make investigations into these problems which will go down to the fundamental facts and enable him to prove his proposition step by step.

These differences in the use of terms, which have grown up as a result of circumstances and environment, make it desirable that we should discriminate carefully and intelligently in applying the funds under a new act which restricts them to investigation. Such discriminating study of the different branches of the subject will be an aid in the development of agricultural science and will lead to a clearer view. It will enable the systematizing of investigations, so that we may go forward step by step in a logical way and as a result of things definitely worked out and proven. Until this is done we shall continue very largely to be groping in the dark, and not laying the foundation for scientific deductions which will help in the next set of problems or in another locality.

Some one has said that "Science seeks to make our knowledge of the small, the invisible, the mysterious, as accurate, as practical as our knowledge of common things;" and that "it seeks to make our knowledge of common things accurate and precise that this accuracy and precision may be translated into action." This fact finds expression in the results of many lines of research in agriculture. The intelligent use of lime is such an illustration, the combating of plant pests, the making and curing of cheese, the handling of milk, and a wide variety of other matters. But these subjects have each passed through their empirical stage before they reached a scientific basis.

For example, there was much experimenting upon the use of lime for land. Applications to some soils gave beneficial results, while on others there appeared to be no benefit, and it was thought by some to exhaust the soil and to be ill advised. A few years ago this represented the status of knowledge and experimentation. The results and the practice were entirely empirical. The lime was usually not needed

by the crops themselves, although it benefited them, but the purpose it served was not known, and there was no way of reasoning whether or not in a particular case lime would be helpful or its use advisable. Soil tests were relied upon for this purpose, and while they might be regarded as experiments, in themselves they did not comprise an investigation.

There were research problems which experience and these experiments had suggested, and after a while these problems became the subject of investigation. The effect of lime in correcting an acid condition of the soil was observed; the relations of this changed reaction to the biological factors of the soil were worked out; and gradually from these and other facts a basis was formed for the philosophy of liming. Through research the knowledge of this common practice had been made "accurate and precise," and this accuracy and precision had been "translated into action."

The combating of plant diseases and insects furnishes similar illustrations. We have come to recognize that investigation of the nature of the disease and the life history and habits of the insect are necessary preliminary steps. The practical problem is the control of the pest; the scientific study of its habits as a basis for control is research or investigation, and this will suggest many experiments, all directed toward a definite purpose and a part or extension of the investigation. But the man who starts in spraying with this and that, trying everything at hand without any basis for his cut-and-try efforts, is testing merely, and although he may hit upon a remedy, his work is in no sense investigation.

In feeding work the case is often on much the same plane. For example, we make a comparison of wheat bran and gluten meal for milk production. One of these feeds gives the better result, as measured by the yield and the financial returns, but often the inquiry stops there. If the question is merely a commercial one, the answer is sufficient, and the farmer can be advised. But we have added nothing to the sum of human knowledge, and we know no better how to feed next year if the relative prices have changed. Is a pound of digestible fat or of protein in one feed of the same value for making milk as that from another source? Or are there some particular constituents whose functions are especially important and give the feed a special value? The real physiological relation of these feeds, or of their respective constituents, to the elaboration of milk remains untouched by such experiments.

Suppose, again, we feed a lot of steers on heavy rations of corn for fattening. Humanity says shelter them in a warm, comfortable barn. They appear after a little to resent this. They are uncomfortable and it is difficult to keep them up to the high rations. Divide them into two lots, and turn one out into the cold with only a shed to shelter

them from the winter winds. The latter lot does better—is more thrifty, eats better, and makes better gains. Is the question answered? Too often it stops here. We have the empirical result, but it is supported by no reason.

Put one of these heavily fed steers into a respiration calorimeter and we find he gives off heat enough under his heavy corn feeding to keep his body warm without artificial protection. The reason has been found. Again, knowledge of common things has been made accurate and precise, and may be translated into action.

In pure science the accumulation of data has in itself often been the object, rather than merely a means to an end; while in experiment station work the case has often been reversed. Here in our haste we have sought mainly the result, without so much attention to accumulating extensive data for broad generalizations.

Research is worthy of the name only as it sets up definite ideals or aims which it strives to attain by scientific methods of procedure. This will involve a definite plan of operations, a thorough consideration of what is known of the subject and its bearings, both practical and scientific, and should lead the experimenter to learn something of the reasons for the results he secures. While the aim should remain fixed, the plan will often have to be modified in detail as the investigation progresses. But too often there appears to be lacking any well-thought-out plan or object; this is developed piecemeal and lacks in directness.

There are certain operations which will always be more or less experimental, as they will depend upon a variety of conditions, either indefinite in extent or combined in such a way as to make the outcome somewhat uncertain. Such operations can not proceed with mechanical exactness, and this very element of uncertainty will lend a charm to the work. But the object to be attained and the line of experiment should be matters of mature consideration. An investigation should presuppose this preliminary.

The line of demarcation between investigation and the lower grades of inquiry is not always clear and sharp, but the character of the problem does not determine this. The lowliest and most common subject may be a proper matter for real investigation. It is the man in charge of the work and his mental attitude toward it which determines whether it shall be a simple test, a conclusive experiment, or a thorough investigation. If he has none of the scientific spirit or sees only the purely practical phase, his work will stop with comparisons and simple experiments; but if he has the true spirit of the investigator and is trained to observe, even though he may not have seen a college class room, his results will contribute something toward establishing a scientific fact.

We have been accused in our experimental work of having the immediately practical results too constantly in mind. The immediately practical work is important and desirable. It has helped to make the American stations strong in the confidence of their constituents. It should be continued and the results carried to the farmer in demonstrations, cooperative experiments, and other popular ways. But it is equally important to get at the scientific facts, which have a wider and more permanent application. Surely there is no conflict between such investigation and the securing of practical results.

Already our station work is coming to assume a more national character. To a noticeable extent we are departing from the view that all work must have a decidedly local flavor or application. The community of interest is being recognized. It is seen that much of the research work has a wider field of usefulness. Its results are applicable in the main to a wide extent of country, and require only to be adapted to local conditions.

If the Adams Act leads us to think more clearly along these lines and to consider the strictly investigation problems which the practical experiments and experience are constantly suggesting, it will have a far-reaching effect and will materially stimulate the original research and investigation it contemplates.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

The determination of available plant food in soil by the use of weak acid solvents, part 2, A. D. HALL and A. AMOS (*Jour. Chem. Soc. [London], 89 (1906), No. 520, pp. 205–222, figs. 3; abs. in Analyst, 31 (1906), No. 361, p. 129*).—The rate of solution of phosphates and the concentration of the extract obtained by continuous extraction of soil samples with water saturated with carbon dioxid and with 1 per cent citric-acid solution were studied in the investigations here reported and graphically represented. The general conclusions reached are summarized as follows:

"(1) The solvent does not at once remove all the phosphoric acid capable of going into solution in the particular solvent employed; instead an equilibrium is established between the phosphoric acid in the solvent and in the soil.

"(2) The concentration of the solution in equilibrium with the soil falls with each successive attack of the soil by the same solvent. This indicates the presence in the soil of several compounds of varying solubility, the mass of the more soluble being small and of the same order as the amounts going into solution in the earlier extracts. When these more soluble compounds have been removed, an approximate constant equilibrium is attained between the phosphoric acid remaining in the soil and that going into solution at each extraction, indicating that after the more soluble compounds have been removed there remains a phosphate in each soil of such low solubility that the amount going into solution at each extraction is independent of the mass present in the soil.

"(3) With soils which have been for many years manured with a particular phosphate, the amounts of phosphoric acid going into solution in successive extractions with 1 per cent citric-acid solution follow a logarithmic law of decrement, indicating the presence of one particular phosphate which dissolves in proportion to the mass of it present in the soil. This law does not, however, hold for ordinary soils which have been variously manured.

"(4) In the case of the Rothamsted soils, the sum of the phosphoric acid dissolved out by the first five extractions with citric acid approximates very closely to the known surplus of phosphoric acid accumulated by the additions of manure to the soil.

"(5) Assuming that the solvent actions of the soil water and of the weak acid solvents employed in the laboratory are comparable, the evidence lends no support to the theory that all soils give rise to a natural soil solution of approximately constant composition, which is not disturbed by the use of fertilizers containing phosphoric acid.

"(6) For the practical purposes of soil analysis, the evidence afforded by a single extraction of the soil for 20 hours with continual shaking is very similar to that obtained from a series of successive extractions by the same solvent, and leads to the same conclusions as to the manurial requirements of the soil."

On the determination of phosphoric acid as magnesium-ammonium phosphate and as ammonium phosphomolybdate, G. JÖRGENSEN (*K. Danske Vidensk. Selsk. Skr., 7. ser., 2 (1905), No. 4, pp. 141–238, figs. 3; abs. in Chem. Ztg., 29 (1905), No. 96, Repert. No. 23, p. 342*).—The author critically reviews the literature of this

subject and reports detailed studies of the conditions affecting the accuracy of the magnesium, molybdomagnesium, molybdic, and citrate methods.

He concludes that either gravimetric or volumetric methods depending upon a constant relation of phosphorus to molybdenum in ammonium phosphomolybdate are not reliable because the composition of the precipitate varies with the conditions of precipitation. The proportion of phosphorus to nitrogen in the ammonium phosphomolybdate is also much too variable to serve as a means of determining phosphoric acid. The solubility of magnesium-ammonium phosphate in ammoniacal water can be determined with reasonable accuracy even when ammonium chlorid, ammonium citrate, as well as magnesium chlorid are present. The equilibrium between magnesium chlorid, ammonium chlorid, and ammonia at about 100° C. can be determined with sufficient accuracy.

In the precipitation of phosphoric acid by means of magnesia mixture in cold solution it is not possible to obtain a precipitate of constant composition either by direct precipitation or by the use of the molybdic or citrate methods. By precipitation in hot solution the conditions of precipitation may be varied considerably without any variation in the proportion of phosphorus to magnesium, and in this way 1 part of phosphoric acid in 1,000 parts of solution may be determined with accuracy.

The molybdomagnesium method worked out by the author on this basis gives accurate results even in the presence of large amounts of strong inorganic acids, silicic acid, and citric acid, as well as of calcium, iron, and aluminum compounds. The citrate method which he proposes, however, is not applicable in case of solutions containing a large amount of silicic acid and can be used with safety only when small amounts of calcium, iron, and aluminum compounds are present. The molybdomagnesium method gives highly accurate results with fertilizers and crude phosphates. The citrate method is recommended only for the determination of water-soluble phosphoric acid in superphosphates.

The molybdomagnesium method proposed is in brief as follows: The solution of phosphate is heated for 10 minutes to about 50° C., shaken, and allowed to cool. A slight excess of molybdic solution is added (formulas for the calculation of the amount of molybdic solution to be used are given), the precipitation and collection and washing of the precipitate being done in the usual way. The precipitate is dissolved in the smallest possible amount of 2.5 per cent ammonia solution, and the solution is heated nearly to the boiling point when neutral magnesia mixture is added drop by drop to precipitate the phosphoric acid. While the solution is cooling it is frequently shaken in order to cause the formation of a crystalline precipitate. After standing 4 hours the precipitate is collected on a filter, ignited, and weighed as usual.

In the citrate method proposed the phosphate solution is mixed with 25 to 30 cc. of neutral ammonium citrate and 25 cc. of 10 per cent ammonia solution, heated to boiling in a covered flask, and the phosphoric acid precipitated with 30 to 40 cc. of neutral magnesia mixture. By repeated stirring or shaking the precipitate separates in crystalline form, and after standing at least 4 hours is collected on a filter, ignited, and weighed as usual.

A list of 269 references to literature of this subject is given.

Citrate solubility of phosphoric acid in fertilizers, J. K. S. Dixon (*Jour. Agr. Sci., 1 (1906), No. 4, pp. 430–443*).—The author reports studies of the solubility of the phosphoric acid of steamed bones, raw bones, fish meals, and guano in alkaline, neutral, and acid ammonium citrate, and 0.1, 1, and 2 per cent citric acid. The results are somewhat inconclusive, but seem to warrant the following conclusions:

"(1) The order of the solvent power of the three solutions of each of the two classes remains the same throughout. In the citrate solutions the order is (descending), (a) neutral, (b) acid, (c) alkaline solution, with only two exceptions, viz., the

raw bone meals. . . . With the free acid the solubilities are in the order of the strength of solution without exception.

"(2) The presence of free ammonia in the citrate solution lowers the solubility and the amount of lowering varies with different products. . . .

"(3) Bones of similar chemical composition and physical properties, and containing practically the same percentage of total phosphoric acid, have different solubilities in the same citrate or citric-acid solution. . . . This observation leads one to infer (a) that the action of the solvent is either not one of simple solution, or (b) that there is a fundamental difference in the phosphates of the bones." The latter view is said to be in accord with that of Gebek (E. S. R., 6, p. 398).

The determination of phosphoric acid in Thomas slag, bone meal, etc., O. BÖTTCHER (*Chem. Ztg., 29 (1905), No. 100, pp. 1293, 1294; abs. in Chem. Centbl., 1906, I, No. 4, p. 282*).—The author summarizes data obtained in over 800 analyses of Thomas slag to show that his method of determining the citric-acid soluble phosphoric acid in Thomas slag (E. S. R., 15 p. 744) gives reliable results when carried out promptly and with proper precautions. Data are also reported to show that the German official method for determining total phosphoric acid in Thomas slag, bone meal, etc., gives reliable results and that it is not necessary, as claimed by Schenke, to neutralize the solution before precipitation, whether nitric acid or sulphuric acid has been used for preparing the solution of the phosphate.

Analytical notes on the superphosphate industry, L. SCHUCHT (*Ztschr. Angew. Chem., 19 (1906), pp. 183-187; abs. in Chem. Centbl., 1906, I, No. 11, pp. 870, 871; Bul Soc. Chim. Paris, 3. ser., 36 (1906), No. 5, p. 558; Analyst, 31 (1906), No. 361, p. 129*).—Drying at 100° C. for 3 hours gives inaccurate results for moisture. Better results were obtained by exhaustion of 2 gm. on the filter with absolute alcohol and ether and weighing the evaporated extract after heating to 120° for 3 hours and the residue on the filter after heating to 40° until the ether disappears.

The author defends his oxalate method of determining free acids against W. Möller's criticism that it gives too low results and is less accurate than the method of alkalimetric titration, reporting further tests which bear out his contention. He condemns the sugar inversion method. The examination of silico-fluorids by titration with one-half normal alkali and phenophthalein and methyl orange is discussed.

Use of the Heraeus electric crucible in the analysis of phosphates, F. HAUSSDING (*Chem. Ztg., 30 (1906), No. 7, pp. 60, 61; abs. in Bul. Soc. Chim. Paris, 3. ser., 36 (1906), No. 4, p. 430; Analyst, 31 (1906), No. 361, p. 128, fig. 1*).—A crucible is described with which it is possible with addition of magnesia to calcine organic phosphates in two minutes. The crucible is also useful for igniting ammonium-magnesium phosphate precipitates.

The industrial analysis of water, E. BOSCH (*Ztschr. Angew. Chem., 19 (1906), pp. 92-95; abs. in Bul. Soc. Chim. Paris, 3. ser., 36 (1906), No. 5, p. 555*).—The author discusses various methods of industrial analysis of water and proposes to test for presence of magnesium and sodium sulphate by adding barium carbonate and phenolphthalein and boiling, the production of a decided coloration indicating that the sulphuric acid is in part combined with magnesium and sodium and not entirely in form of calcium sulphate.

The determination of nitrous acid in water analysis, G. LUNGE (*Ztschr. Angew. Chem., 19 (1906), No. 7, p. 283*).—The author calls attention to the fact that some analysts have confused his method for the detection of nitrous acid in sulphuric acid with the colorimetric method proposed by him for the determination of nitrites in water.[a] In the latter case no sodium acetate is used with the "Lunge reagent" (a mixture of an acetic-acid solution of α-naphthylamin and a water solution of sulfanilic acid).

[a] Ztschr. Angew. Chem., 7 (1894), p. 348.

The separation of solutes from solvents by absorbing media, F. K. CAMERON and J. M. BELL (*Abs. in Science, n. ser., 23 (1906), No. 583, p. 324*).—This is an abstract of a paper presented at the New Orleans meeting of the American Association for the Advancement of Science.

A study of the absorption of dyes from water by blotting papers, cotton, and soil is reported, from which it is concluded that the capillary movements of solutes through absorbing media follow an empirical law—"$y^n=kt$, where y represents the distance through which the movement has taken place, t the time of movement, and n and k constants depending on the nature of the substances used, although n approximated 2.3 in most of the cases to which the formula has so far been applied." This formula holds, however, only when neither the distance nor time is large.

Chemistry of the proteids, G. MANN (*London and New York: The Macmillan Co., 1906, pp. XVIII + 606, dgms. 6*).—It has been the author's purpose to summarize, classify, and discuss the available data regarding the composition, structure, and characteristics of proteids, the principal topics dealt with being the reaction of albuminous substances, their dissociation products, the synthesis of albumins and their constitution, albumoses and peptones, salts of albumins, halogen albumins and allied matter, and physical properties and classification of albumins.

As the author points out, special stress has been laid on the proposition that cellular metabolism is a cyclic event and not a question of anabolism and catabolism, and throughout the volume the biological aspect of chemistry has been constantly kept in mind. The synthesis of albumins, as far as it was known up to September, 1905, is given in full. The carbohydrate radicals of proteids are dealt with fully because of their biological importance, and for the same reason special attention has been paid to sulphur.

A new view has been advanced, namely, that so-called neutral salts of albumins are in reality not neutral, for it is their very want of neutrality which allows them to dissolve in water, and which also enables them to dissolve globulins or to keep these compounds in solution.

The subject of autodigestion of nucleo-proteids has been considered at length, as it is believed that it will in the near future throw a great deal of light on the question of metabolism.

A purely chemical classification has been adopted for proteids, "the individual substances being arranged in such a way as to lead from the lower members of a series to the higher ones—from the less to the more highly oxidized forms—and from open chain to ring compounds."

A full index and a bibliography add to the value of the volume. The author states that his book is based on the second edition of O. Cohnheim's *Chemie der Eiweisskörper* (E. S. R., 16, p. 439), but that a large amount of additional matter has been included.

Practical elementary guide for the examination and analysis of milk, A. FARINES (*Guide pratique et elementaire pour l'examen et l'analyse des laits. Paris, 1905; rev. in Rev. Gén. Lait, 5 (1906), No. 13, p. 303*).—This work is based upon a course given in a dairy school and consists of practical methods for the examination of milk, the more rapid and simple methods being given the preference inasmuch as the book is designed not only for students in dairy courses but for practical dairymen.

Experiments with the "sin-acid" butyrometer, J. ADORJÁN (*Ztschr. Landw. Versuchsw. Oesterr., 9 (1906), No. 3, pp. 117-125*).—Comparative tests of the Sichler nonacid method and the Gerber method are reported, the author concluding that at present the nonacid method can not supplant the simpler and more rapid acid method of Gerber. It is considered probable, however, that with improvements the nonacid method may become of great practical importance.

Rapid analysis of butter, H. W. CHARLTON (*Dairy, 18 (1906), No. 208, p. 101*).—This method consists in separating the melted butter into two layers by means of a centrifuge and observing the volume of each layer at 100° C. The percentage by volume of the lower layer consisting of water, salt, and curd is considered practically the same for normal butter as the percentage of water by weight. With abnormal butter the method does not give the correct percentage of water by weight, but indicates, according to the author, that there is something wrong. The author states certain conditions that must be observed in the use of this method which is considered better than any partial gravimetric analysis for showing the relative value of butter samples.

Note on the method of silver indexes for the detection of cocoanut oil in butter, F. JEAN (*Ann. Chim. Analyt., 11 (1906), No. 4, pp. 121-124*).—The author's investigation leads him to conclude that the method of silver indexes (E. S. R., 17, p. 834) may confirm the presence of cocoanut oil in butter, but that negative results are not in all cases to be considered as invalidating results obtained by other methods, especially by the method of Muntz and Coudon (E. S. R., 15, p. 850) when the butter is adulterated with a mixture of different fats.

Microscopy of vegetable foods and condiments, J. MOELLER (*Mikroskopie der Nahrungs- und Genussmittel aus dem Pflanzenreiche. Berlin: Julius Springer, 1905, 2. ed., pp. 599, figs. 599; rev. in Österr. Chem. Ztg., 9 (1906), No. 5, p. 69*).—This volume, which describes the histological structure of foods and condiments of vegetable origin with a view to their identification under the miscroscope, has been thoroughly revised, and the author states that he has had the cooperation of A. L. Winton in the work.

The quantitative estimation of the lecithans, W. KOCH and H. S. WOODS (*Jour. Biol. Chem., 1 (1906), No. 2-3, pp. 203-211*).—Using methods which are described, lecithins and kephalins were determined in a number of samples of muscle of different sorts, submaxillary glands, pancreas glands, testicles, lung, kidney, liver, white and yolk of egg, mothers' milk, cows' milk, bread, etc.

The identification of horse and colt flesh by means of its glycogen content, M. MARTIN (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 5, pp. 249-266*).—A comparison of different methods of estimating glycogen was undertaken with a view to devising a means of identifying horse flesh in sausage and other food products, and a number of determinations of the glycogen content of different sorts of flesh were made. According to the author, horse flesh in sausage may be detected by determining the glycogen content, and Pflüger's method is best suited for the purpose.

Sulphate and sulphur determinations, O. FOLIN (*Jour. Biol. Chem., 1 (1906), No. 2-3, pp. 131-159*).—Methods of determining sulphur were studied and modifications and precautions suggested which the author considers necessary to insure accuracy, the investigations as a whole being carried on with reference to the determination of different sorts of sulphur in urine.

The method for determining inorganic sulphates is as follows: Add 5 per cent barium-chlorid solution, drop by drop, preferably by means of an automatic dropper, to 25 cc. of urine diluted with about 100 cc. of water and acidulated with 10 cc. of dilute hydrochloric acid. The solution must not be shaken, stirred, or otherwise disturbed while the barium chlorid is being added. At the end of an hour or later shake and filter through a Gooch crucible. Wash the precipitate with about 250 cc. of cold water, dry, and ignite.

Methods are also given for total sulphates, ethereal sulphates, and total sulphur.

Bluestone and formalin, T. MACFARLANE (*Lab. Inland Rev. Dept. [Canada] Bul. 115, pp. 6*).—Analyses of 23 samples of copper sulphate and 11 of formalin are reported Six of the samples of copper sulphate were adulterated or inferior in quality and 1 sample of formalin showed only 25.6 per cent of formaldehyde.

The interpretations of chemical analyses for farmers, H. Ingle (*Transvaal Agr. Jour., 4 (1906), No. 14, pp. 330-357*).—The object of this article is "to explain, in as popular a manner as possible, the practical meaning of analyses of some of the more important substances produced or consumed in agriculture." The main topics discussed are soils, manures, feeding stuffs, and antiseptics.

Agricultural chemistry during the second half of the year 1905, W. Zielstorff (*Chem. Ztschr., 5 (1906), Nos. 4, pp. 73-75; 5, pp. 99-101; 6, pp. 123, 124*).—Brief reviews are given of articles relating to the nutrition of plants and animals.

Thirteenth annual report of the committee on atomic weights. Determinations published in 1905, F. W. Clarke (*Jour. Amer. Chem. Soc., 28 (1906), No. 3, pp. 293-315*).

METEOROLOGY—WATER.

Outlines of tropical climatology, G. M. Giles (*Climate and Health in Hot Countries. London: John Bale, Sons & Danielsson, Ltd., 1904, pt. 2, pp. 109*).—This article discusses the general characteristics of tropical climates, and the more important data determining the character of such climates, including temperature (mean and range), relative humidity, amount and distribution of rainfall, cloudiness, and amount, daily distribution, and direction of the wind, and summarizes all available data bearing upon the special characteristics of the climate of the countries lying in the Mediterranean Basin, including Algeria, Malta, Cyprus, and Egypt; other regions of the African Continent, including Soudan, Abyssinia, region of the Great Lakes, Kongo Basin, West Coast, Sierra Leone, Gulf of Guinea, East Coast, Madagascar, Mauritius, Red Sea and its coasts including Somaliland; the Asiatic Continent, including Palestine, Persian Gulf region, Arabian Peninsula, India and Ceylon, Indo-Malay Peninsula, Straits Settlements, Siam, Cochin China, China, Malay Archipelago; Australia, Pacific Islands, the Southern United States, Mexico, Central America and the Isthmus of Panama, West Indies, Bermuda, Madeira, and various places in South America.

Monthly Weather Review (*Mo. Weather Rev., 33 (1905), Nos. 12, pp. 515-570, figs. 8, charts 11; 13, pp. XV+571-591, charts 8*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the month of December, 1905, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., No. 12 contains special contributions on Doctor Margules on the Energy of Storms, by S. T. Tamura; Air and Water Temperatures, by W. F. Cooper; International Meteorological Definitions and Symbols, by E. R. Miller; Deposit of Ice Columns (illus.), by E. R. Miller; The Climate of Madison, Wis. (illus.), by J. L. Bartlett (see p. 941); Tornado Insurance (illus.), by H. E. Simpson; Norway's Contributions to the Natural Sciences, by R. S. N. Sartz; and A Visit to European Observatories, by G. J. O'Connor; and notes on the mild weather of December, 1905, meteorology in India, meteorological maps for school use, Thomas R. Rodman, meteorology in Holland, a large meteor, Weather Bureau men as instructors, special meteorological stations for special studies, and cyclones and anticyclones.

No. 13 contains a table of contents, list of corrections, additions, and changes, and an index for volume 33; a report of the Forecast Division; report of the Chief of the Weather Bureau for the fiscal year ended June 30, 1905; and a summary of observations on pressure, temperature, precipitation, humidity, cloudiness, and other meteorological phenomena "based essentially upon data received from about 166 regular Weather Bureau stations, 33 regular Canadian stations, and from such climate and crop sections as have forwarded their annual summaries in time."

The mean pressure of air departed considerably from the normal during the year, being "below the normal in Maine, Vermont, northern New Hampshire, extreme eastern Massachusetts, the Peninsula of Florida, the western portions of the southern

and middle Plateau and southwestern portions of the northern Plateau regions, and the south and middle Pacific and southern portion of the north Pacific districts; elsewhere it was above the normal. . . . The mean temperature was above the normal in the Florida Peninsula, upper Lake region, North Dakota, Missouri Valley, and the northern slope, northern Plateau, and Pacific regions; elsewhere it was below the normal." The departures in temperature were as a rule small and "in but few instances exceeded 1°, the greatest, +2.5°, occurred over the Red River of the North Valley. . . . Over the country east of the Mississippi River the distribution of precipitation was not well marked as to geographic districts, as excesses and deficiencies of considerable amount occurred in the same district. To the westward of the Mississippi River the lines of demarcation between the excesses and deficiencies were much better defined as to geographical districts. Considering the geographic districts as a whole the precipitation for the year was above the normal in the Florida Peninsula, Gulf States, Missouri Valley, slope and southern and middle Plateau and south Pacific regions; elsewhere it was below the normal."

Summary of meteorological observations, January to June, 1904, F. H. LOUD (*Colo. Col. Studies, 11 (1904), Sci. Ser. Nos. 33-35, pp. 54-76*).—The equipment of Colorado College for meteorological observations is described, the methods of reduction are explained, and observations on temperature, pressure, precipitation, humidity, sunshine, and wind movement are reported.

Determination of number of hours of possible sunshine at Colorado Springs, F. H. LOUD (*Colo. Col. Studies, 11 (1904), Sci. Ser. Nos. 33-35, pp. 77-82*).—A description of the method used in making the determination and the results obtained in 1888 are reprinted from an earlier publication (Colorado Weather, April, 1889).

Meteorology for the year 1905, J. DERÔME (*Rev. Sci. [Paris], 5. ser., 5 (1906), No. 2, p. 53*).—This a brief summary of observations at Paris on atmospheric pressure, temperature, and rainfall compared with similar observations for 1903 and 1904. The characteristic feature of the weather in the region of Paris during the year was excessive rainfall. The rainfall at Park St. Maur was 641.1 mm. in 1905 as against 541 mm. in 1903 and 527 in 1904, the mean for 1841-1890 being 594 mm. There were 169 rainy days in 1905, as against 159 in 1903 and 141 in 1904. The wettest month was June, 108 mm. The heaviest daily rainfall, 27.2 mm., occurred August 28.

The mean temperature of the year was 9.87° C., being lower than that of 1903 (10.38°) and 1904 (10.4°). The mean temperature for the period 1841-1890 was 9.93°. The highest temperature observed in 1905 was 32° C., the lowest −10.9°.

The mean annual pressure was 758.97 mm. The normal for the period 1841-1890 was 757.6. The lowest barometer observed in 1905 was 730.3 mm., the highest 782.1.

Meteorological summary for 1905, H. DUFOUR and D. VALET (*Chron. Agr. Vaud, 19 (1906), No. 3, pp. 49-54*).—Observations at Lausanne on temperature, precipitation, sunshine, temperature of the soil, and general weather conditions are briefly summarized for the year and compared with averages for previous years and neighboring places.

Practical meteorological studies and comparative observations at the stations of Beaulieu, Sevres, and Vacquey for the year 1903, G. EIFFEL (*Études pratiques de météorologie et observations comparées des stations de Beaulieu, Sèvres et Vacquey pour l'année 1903. Paris: L. Maretheux, 1905, pp. 377; rev. in Rev. Gén. Sci., 17 (1906), No. 3, p. 149*).

Meteorological observations, G. GINESTOUS (*Bul. Dir. Agr. et Com. [Tunis], 9 (1905), No. 37, pp. 590-614*).—Tabular summaries are given of observations, June to November, 1905, at a number of places in different parts of Tunis on precipitation, temperature, atmospheric pressure, humidity, evaporation, cloudiness, direction of the wind, and casual phenomena. A brief account is also given of meteor

ological observations made in Tunis during the eclipse of the sun August 30, 1905. These relate to temperature, relative humidity, wind movement, cloudiness, etc.

Meteorological Chart of the Great Lakes, A. J. HENRY and N. B. CONGER (*U. S. Dept. Agr., Weather Bur., Met. Chart Great Lakes, 1905, No. 2, pp. 12, chart 1*).—This is a summary of observations on storms and high winds over the lake region, 1905; precipitation and lake levels, November, 1904, to October, 1905; opening and closing of navigation, 1905; vessel passages at Detroit, Mich., during the season of navigation; and wrecks and casualties during 1905.

Climate of the Pacific coast, A. MCADIE (*Outing Mag., 47 (1906), No. 5, pp. 555–558*).—The more characteristic features of temperature, rainfall and snowfall, sunshine and evaporation are discussed and compared with similar climatic features of the Atlantic coast. It is shown that the temperature is less variable throughout the year on the Pacific coast than on the Atlantic coast, although, owing to the topography of the country, wide differences of temperature occur within short distances.

"The orography of the Pacific coast is different from that of the Atlantic. The mountains stand in great ranges, inclosing many valleys running as a rule parallel to the coast. The angle of inclination of the mountains to the rain-bearing winds is favorable for heavy rainfall, north of the thirty-fifth parallel. In southern California the mountains trend east and west, and much drier weather is the rule. While the inclination of the mountains is an important factor in rain production, the chief factor, of course, is the movement of the air due to the great pressure areas."

The heaviest rainfall in the country occurs on the north Pacific coast; the least in southeastern California, varying in 1904 from nothing in the latter region to 145 in. in eastern Oregon. Due to the influence of the mountains the snowfall is heavier in many parts of the Pacific coast than in most portions of Canada, varying from a trace in San Francisco to 360 in. at Fordyce.

"Evaporation data are scant, but it is likely that the highest rate of evaporation in our country will be found in California. At Calexico, from July 1, 1903, to July 1, 1904, the evaporation measured 108 in., i. e., 2,743 mm., or over 7 mm. per day."

The Pacific coast is thus shown to be a region of climatic contrasts and contradictions. The mountains favor diversity of climate and give rise to many so-called "local" climates.

The climate of Madison, Wis., J. L. BARTLETT (*Mo. Weather Rev., 33 (1905), No. 12, pp. 527–534, figs. 6*).—Meteorological observations at Madison, beginning as early as January, 1853, are summarized, and from them the climatic characteristics of the place are deduced (see also E. S. R., 17, p. 224).

As regards the general climatic situation, it is stated that "southern Wisconsin enjoys a type of climate peculiar to continental interiors, characterized by great extremes of temperature. As it lies on the windward side of Lake Michigan, its atmospheric conditions are but slightly influenced by the Great Lakes. In general this is a region of warm summers, with occasional periods of extreme heat, which may be interrupted by destructive local storms. The winters are somewhat cold and stormy, with frequent cold waves. The rainfall is sufficient for raising excellent crops, and is heaviest during the spring and early summer and least in the winter. About 50 per cent of the possible duration of sunshine is recorded at the surface of the earth."

Madison occupies a narrow strip of land lying directly between Lakes Mendota (15 square miles in area) and Monona (5 square miles in area), and "the tendency of the lakes is to lower the mean maximum temperatures throughout the year, to raise the mean minimum, and thus to decrease the mean daily range. . . . The average date of last killing spring frosts is April 21, and the earliest in the fall October 17. Comparing these dates for a number of years with the dates of similar

phenomena at Harvey, Wis., which is directly east of Madison, away from any small lakes, but nearer Lake Michigan, it is found that at Harvey killing frosts occur, as a rule, two weeks later in the spring and two weeks earlier in the fall. Thus the growing season is lengthened about one month at Madison, apparently by the influence of the presence of lakes Mendota and Monona."

The average annual rainfall during 36 years has been about 37 inches. "Dry spells are of almost annual occurrence at Madison, and occasionally pronounced droughts occur."

"The prevailing winds vary from northwest during November–March, to south during the remainder of the year. These two directions prevail nearly equally."

A first report on the relations between climates and crops, C. ABBE (*U. S. Dept. Agr., Weather Bur. Bul. 36, pp. 386*).—This bulletin summarizes the views of investigators and observers on this subject which had been published up to 1891. Numerous extracts from the more important contributions to the subject are included. "The work is prepared with the idea that it will be especially useful to the teachers of the agricultural colleges and the investigators of the agricultural experiment stations."

The subject is presented from three points of view: (1) Physiological, including results of studies such as those of Sachs and other physiological botanists; (2) experimental, including results obtained by the methods pursued by agricultural experiment stations, and botanical and biological laboratories; and (3) statistical, embodying the results obtained by "comparing the statistics of the successive annual harvests in the country at large with the statistics of the prevailing climatic conditions."

The bulletin is divided into four parts as follows: (1) Laboratory work, physiological and experimental, (2) open air work—experience in natural climates, (3) statistical farm work, and (4) authorities.

The author emphasizes especially "the importance of a climatic laboratory and the methods that must be pursued in order to evolve new varieties of crop plants adapted to special climatic conditions."

It is said that "a continuation of this study, bringing the subject up to date, is contemplated."

Weather forecast, D. E. HUTCHINS (*Rev. in Agr. Jour. Cape Good Hope, 28 (1906), No. 1, pp. 98-105*).—This is a review of a paper by Mr. Hutchins and its discussion before the South African Philosophical Society on long-period forecasts and of the various cycles on which they are based, namely, (1) the sunspot or solar cycle of 11.11 years; (2) a cycle, with alternating periods of 9 and 10 years, termed the storm cycle; and (3) a cycle with alternating periods of 12 and 13 years, termed Meldrum cycle.

The author's conclusions with regard to the application of these cycles in weather forecasting are as follows: "(1) The three main weather cycles are of general application throughout South Africa. I had considered in 1888 that the storm cycle brought practically no rain to the eastern stations, and Meldrum's cycle little or no rain to western stations. The experience of the last 17 years shows that both may extend east and west beyond their area of greatest influence. (2) Observations from the northern stations are as yet too short to draw safe conclusions, but they seem to indicate that the pulse of heavier rainfall occurs a season earlier at northern stations (Transvaal and Rhodesia). (3) There are obscure indications of a tendency to rain at the sunspot minimum, and possibly the irregular rain of 1902 may be accounted for as a sunspot minimum rain. It so happens that the normal sunspot minimum periods (11-22-33-44-55.5-67-78-89-100 in each century) have since the year 1841 so frequently coincided with other cycles that the exact influence of the sunspot minimum is difficult to trace. In the long chain of the Royal Observatory rainfall figures, the sunspot minimum has had no practical influence till we get to the doubtful case of the 1902 rains. At other stations sunspot minimum rains are more clearly traceable.

Note the rains of 1866 at Durban, of 1900 at Bulawayo, Salisbury, and Johannesburg. Further observations are necessary before it can be stated what is the exact influence of the sunspot minimum on South African weather. (4) Up to the present, the direct influence of Brückner's 35-year cycle is inappreciable in South African weather."

Forecasts for the year 1906, based on the weather cycles, are given.

The atmosphere, G. BLEUEL (*Jahresber. Agr. Chem., 3. ser., 7 (1904), pp. 3-18*).—A review is given of literature relating to this subject published during 1904, classified as follows: Constituents (chemistry) of the atmosphere and of atmospheric precipitation, and physics of the atmosphere (meteorology).

Water, A. HEBEBRAND (*Jahresber. Agr. Chem., 3. ser., 7 (1904), pp. 18-25*).—A review is given of the literature relating to this subject published during 1904, classified as follows: Spring, drain, and irrigation water, and sewage and the purification of sewage waters.

A method of determining the turbidity of water, J. F. LIVERSEEGE (*Jour. Soc. Chem. Indus., 25 (1906), No. 2, p. 45*).—A method based upon the ability to read standard type of different sizes through a column of water 2 ft. long at a distance of 2½ ft. is described, the results being termed "turbidity expressed in feet of distance to read standard type."

On the Wartha method for determining hardness in water, H. SICHLING (*Deut. Gerber Ztg., 1905, pp. 271-276; abs. in Chem. Centbl., 1905, II, No. 13, pp. 982, 983*).—The author concludes from his studies of various methods that Wartha's method is simple, easy of execution, and of value especially for tannery chemists. It was preferable to Clark's method in cases in which the use of soap solutions presented difficulties. It must, however, be used with great care in waters naturally containing soda or which have been softened by the use of this substance.

Notes on investigations relating to rain water, H. M. KNIPSCHEER (*Pharm. Weekbl., 42 (1905), pp. 1042-1045; abs. in Chem. Centbl., 1906, I, No. 5, p. 395*).—The author refers to investigations by Nonhebel on the importance of chlorin in rain water, and describes a simple method, using fluorescin, of determining the depth to which rain water sinks into the soil.

The disappearance of water from the upper layers of the soil, W. GÖTZ (*Vrtljschr. Bayer. Landw. Rat., 10 (1905), No. 3, pp. 391-419*).—A general discussion is given of reduction of humidity due to removal of forests, disappearance of bodies of water, and increased percolation, and of the sources of the supply of water in the soil.

Influence of forests on underground waters, M. RINGELMANN (*Jour. Agr. Prat., n. ser., 10 (1905), No. 49, pp. 721-723, figs. 3*).—The effect of forests in lowering the level of phreatic waters and in conserving moisture and regulating streams is briefly discussed.

The drinking water question (*Het Drinkwatervraagstuk. 1905, pp. 30, pls. 5*).—This is an account of a discussion of this subject at the Flemish Congress of Natural Science and Hygiene held at Aalst September 23 and 24, 1905, including articles by A. J. J. Vandevelde on Spring Water as a Source of Supply for Cities, and by I. Bauwens on Sanitary Examinations of the Water of a Number of Springs, with general discussion of the subject.

The hygienic rôle of germs in water, F. MALMÉJAC (*Rev. Sci. [Paris], 5. ser., 5 (1906), No. 6, pp. 176-178*).—The author concludes that a water containing a large number of saprophytic germs is as a rule badly filtered and protected and should not be used for drinking purposes. The same is true for waters containing a considerable number of *Bacillus coli communis*, and of course for all waters containing germs which are undoubtedly pathogenic.

The present status of waste water purification by biological methods, THUMM (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 1905, No. 5; abs. in Centbl. Bakt. [etc.], 2. Abt., 15 (1906), No. 24, pp. 762, 763*).—A general review of this subject, especially as affecting England and Germany.

Effect of copper sulphate on the bacteriological and chemical constituents of large bodies of water, W. R. STOKES and J. B. THOMAS (*Amer. Med., 10 (1905), No. 26, pp. 1075-1078, fig. 1*).—The results of a limited number of experiments with copper sulphate on a swimming tank in Baltimore filled from the general water supply of the city are reported, from which "it would seem that in fairly pure water a dilution of 1 to 100,000 can be depended upon greatly to reduce the algæ and fermentative bacteria, and also clear the water by precipitating the matter in suspension. In moderately polluted water the fermentative bacteria are not destroyed."

SOILS—FERTILIZERS.

Renovation of worn-out soils, W. J. SPILLMAN (*U. S. Dept. Agr., Farmers' Bul. 245, pp. 16*).—The principal lessons which this bulletin is intended to enforce are briefly summarized as follows: "To build up and maintain fertility in the soil, feed a large part of the crops, and return the manure to the land. If manure is not available, plow under crops grown for the purpose. Plow deep (but do not subsoil). Grow leguminous crops for the nitrogen they add to the soil.

"Commercial fertilizers and lime may be important means of improving the soil, but the fertilizer requirements of different soils and different crops in different seasons are so little understood that we are not yet in a position to make positive recommendations that are of general application."

Present definitions of soil fertility, W. H. JORDAN (*Agr. of Mass., 1904, pp. 121-155*).—This paper discusses the various theories of soil fertility, particularly those advanced in Bulletin 22 of the Bureau of Soils of this Department. The author's views with reference to methods of soil management necessary to maintain fertility are summarized as follows:

"(1) Thorough tillage, with efficient machinery, to be given if possible when the moisture conditions of the soil admit of satisfactory pulverization.

"(2) Frequent surface tillage at times of scanty rainfall, in order to conserve the supply of soil moisture.

"(3) A sufficiently rapid rotation of crops to insure good soil texture, to allow the necessary frequency of applying fertilizing material, and as a main result to secure a paying stand of crops.

"(4) The introduction into the soil at frequent intervals of an amount of organic matter necessary to proper soil texture and water-holding power, either by application of farm manures, by plowing under soiling crops, or by the rotting of the turf.

"(5) The scrupulous saving of all the excrement of farm animals, both solid and liquid.

"(6) The purchase of plant food with due reference to the needs of the farm and to the system of farm management prevailing.

"(7) The maintenance in the soil of those conditions of drainage and aeration which promote the growth of desirable soil organisms, and the introduction into the soil, when necessary, of such organisms as are essential to the growth of particular plants."

The analysis of soils, E. A. MANN (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 2, pp. 141-144*).—The value of soil analysis for determining the fertility of soils, especially Dyer's method of determining availability of soil constituents, is briefly discussed. Studies which have been made indicate that the chemical methods are of value in case of West Australian soils.

Fertility studies on Wooster soil, A. H. SNYDER and C. L. COOK (*Ohio Sta. Bul. 167, pp. 85-119*).—An account is given in this bulletin of experiments made by the Bureau of Soils, cooperating with the Ohio Station, "to determine whether the results obtained by its wire-basket and aqueous-extract methods of studying the productiveness and manurial requirements of soils [E. S. R., 17, p. 227] were in accord with

those secured through plat experiments." The character of the soil, which is that of the 5-year rotation plats at Wooster, is described (E. S. R., 16, p. 752) and its previous history and treatment is explained.

A series of experiments with wheat in wire baskets to determine the effect of manures, fertilizers, and lime, and to study the effect of increasing (adding sulphuric and tartaric acids) or neutralizing (with sodium carbonate and hydroxid as well as with lime) the natural acidity of the soil is reported.

Cultures with the soil extract are reported in which the attempt was made "to determine whether or not the causes of a lowered productiveness are transmitted to the aqueous extract, and if so, whether these can be corrected by the various treatments found to be effective in the soil itself."

The results obtained by the above methods are compared with those obtained in plat experiments with like fertilizer treatment in a 5-year rotation on the same soil. The results are thus summarized:

"The experiments carried on . . . . during 11 years by the plot method and those carried on during the last 6 months by the culture methods of soil in wire baskets and of soil extract in bottles, agree in showing that the best results which have been obtained are those following the application of nitrate of soda in combination with acid phosphate, the application of lime or the application of manure. Being submitted to a five-crop rotation, this soil soon responds markedly to applications of phosphoric acid, and the effect of the continued application of this fertilizer is undoubtedly cumulative, this point being brought out equally well by both field and culture methods.

"Additional conclusions brought out by the basket and bottle cultures are as follows:

"(1) The character of the soil, as far as its ability to produce plants is concerned, is transmitted to its extract, as is shown by the fact that the same results may be obtained by growing plants in the extract as are obtained by growing them in the soil itself.

"(2) The soil is acid, probably with an organic acid, but its present low productivity is not due to the acidity.

"(3) The beneficial effect of lime is probably due in great measure at least to other causes than its power to neutralize the soil acidity.

"(4) The evidence points strongly to the conclusion that this soil contains some toxic materials somewhat similar to, but still differing in some of their properties from, those found in the Takoma lawn soil investigated by the Bureau of Soils of the U. S. Department of Agriculture [E. S. R., 17, p. 340]. It seems probable that the effect of lime on Wooster soil is largely due to its action, in some way as yet undetermined, upon these toxic bodies, and it may be that a large part of the effect produced by fertilizers and stable manure is due to some similar action on the part of these latter substances."

In his comments upon the general results, Director Thorne says: "The outcome of this work has been that results obtained in two or three weeks' time are in general agreement with field tests which required an entire season for their execution." He adds further, however, that "no single season's field work on a particular soil is a sufficient basis on which to formulate a definite prescription for the fertilization of that soil, and it is highly probable that we shall find the same law holding good in the conduct of the [wire-basket] method of investigation . . . . All that can be said of this method at present—and this is much—is that it promises to be a very useful help in one of the most intricate lines of investigation science has yet undertaken—that of the maintenance of soil fertility."

Fertility studies on Strongsville soil, A. H. SNYDER and C. L. COOK (*Ohio Sta. Bul. 168, pp. 119-138*).—The experiments reported in this bulletin were similar in plan and purpose to those with Wooster soil noted above, the experiments being

confined, however, to tests with the wire-basket method. The results obtained with the heavy clay Strongsville soil are thus summarized:

"(1) The soil has been greatly improved by placing it in good physical condition such as is obtained in potting.

"(2) The soil is naturally fertile so far as plant food is concerned, as shown not only by the basket cultures but as indicated by the result of the chemical analyses reported in Bulletin 150 of the Ohio Agricultural Experiment Station.

"(3) The effect of replanting the untreated soil in pots with wheat immediately after a crop of wheat has been grown in the same is to reduce the growth of plants approximately 50 per cent.

"(4) Lime appears to have some beneficial effect in the baskets. Heavier applications than the results in the baskets would seem to indicate have been found practicable in the field, probably owing to the physical effect which this substance has upon the soil.

"(5) No appreciable difference is detected between the results obtained with ground quicklime and hydrated lime.

"(6) Little if any beneficial effect has been shown from the application of mineral fertilizer salt to this soil after it has been placed in good physical condition, although an application of these salts, especially acid phosphate, gives a decided increase when the soil is in the condition found in the field.

"(7) Manure produces a small increase in the growth of plants in pots but not as great an increase as is secured from its application in the field. This is probably due to the fact that in the field its effect is mainly due to its physical action.

"(8) The effect of green manure is negative upon the crop planted immediately after it was applied, but gives a large increase in crops planted subsequently."

The conclusions drawn from these results are as follows:

"(1) The soil of the Strongsville test farm is sufficiently rich in the mineral constituents of fertility for abundant crop production, but such is not secured on account of the unfavorable physical condition of the soil.

"(2) An improvement of the physical condition of the soil, such as is obtained in the process of potting, or by the application of lime, barnyard manure, or green manure, gives a marked increase in the growth of the plants and apparently, to a great measure, obviates the need of the addition of mineral fertilizers."

Rubber soils, H. N. Ridley (*Agr. Bul. Straits and Fed. Malay States, 4 (1905), No. 10, pp. 388, 389*).—This is a brief note on a circular issued by the Royal Botanic Gardens, Ceylon, which gives a series of analyses of soils and of fresh and decaying leaves, twigs, etc., of the Para rubber plant. These analyses show that in sweeping off the ground 10,000 lbs. of fallen leaves and twigs, about 58 lbs. of lime, 36 lbs. of magnesia, 22 lbs. of potash, and 12 lbs. of phosphoric acid are lost to the soil.

Behavior of "soluble" phosphoric acid and its movements in the soil, W. Hoffmeister (*Das Verhalten der "löslichen" Phosphorsäure und ihre Wanderung im Boden. Insterburg: Bittnersche Druckerei, 1904; rev. in Centbl. Agr. Chem., 34 (1905), pp. 817–820; Jour. Chem. Soc. [London], 90 (1906), No. 520, II, p. 120*).—The results of 5 years' pot experiments on this subject are reported. Solubility in ammonium humate was used as a means of tracing the variations in the amount and distribution of the assimilable phosphoric acid at different periods.

The results indicate that long continued culture did not completely exhaust phosphoric acid soluble in ammonium humate. The reduction in the amount of such phosphoric acid was apparently due to withdrawal by crops and not to reversion to insoluble forms. Notwithstanding the constant removal of phosphoric acid from the subsoil, the relative amount of soluble phosphoric acid was found to increase from the surface downward, indicating a downward movement of the phosphoric acid in the soil.

Studies of the effect of heating the soil on the solubility of the phosphoric acid showed that samples of peat which in their natural condition did not contain determinable amounts of phosphoric acid soluble in ammonium humate yielded 0.006 to 0.061 per cent when heated at 160° C.

The removal of soluble salts from soils, M. RINGELMANN (*Jour. Agr. Prat., n. ser., 11 (1906), No. 6, pp. 174, 175*).—Methods of flooding and drainage employed for this purpose in Egypt are briefly described.

Progressive changes in soil moisture, W. GÖTZ (*Met. Ztschr., 23 (1906), No. 1, pp. 14–24*).—It is maintained in this article that in the course of centuries there has been a progressive draining away of the moisture from the upper layers of the soil, especially of the higher lands, a reduction of the humidity of the air, and consequent increase in temperature variations between seasons and between night and day.

Underground studies, C. OCHSENIUS (*Helios, 22 (1905), pp. 37–66*).—Accounts are here given of studies of underground conditions in the region of Venice and of Frankfurt, the first with especial reference to the sinking of the soil, resulting in the fall of the Campanile, and the second with reference to the occurrence of salt deposits. The order of occurrence of the salt deposits (especially potash salts) under Frankfurt, their extent, composition, and uses, are discussed.

Soil physics laboratory guide, W. H. STEVENSON and I. O. SCHAUB (*New York: Orange Judd Co., 1905, pp. 80, pl. 1, figs. 16*).—This book, which is the outgrowth of the laboratory instruction given at the Iowa Agricultural College, is designed "to present to the instructor and the student a carefully outlined series of experiments in soil physics." It includes a series of 40 exercises accompanied by questions on various features of the experiments outlined.

"An earnest effort has been made to outline the exercises briefly and clearly in order that the student may proceed with the work without loss of time and without confusion. The exercises are also listed in a logical order with reference to their relation to each other and the skill required on the part of the student." The book is an extension of a pamphlet on the same subject issued by the department of agronomy of the Iowa Agricultural College. It meets in a very satisfactory manner a widespread and growing demand for a simple text-book on the subject.

Economic geology of the United States, H. RIES (*New York and London: The Macmillan Co., 1905, pp. XXI+435, pls. 25, figs. 97*).—It is stated that this work covers essentially the ground which is gone over in the elementary course in this subject at Cornell University, and it is hoped that it will prove useful as a text-book in other colleges. The arrangement differs from that of other books on the same subject in that the nonmetallic minerals are discussed first and the metallic minerals last, the reason for this being that the non-metallic minerals are much more important and valuable than the metallic and because it leads from a discussion of the simpler to the more complex forms of mineral deposits.

The book contains chapters on coal; petroleum, natural gas, and other hydrocarbons; building stones; clay; lime and calcareous cements; salines; gypsum; fertilizers; abrasives; minor minerals; water; soils and road materials; ore deposits; iron; copper; lead and zinc; gold and silver; silver-lead; aluminum, manganese, and mercury; and minor metals. At the end of each chapter there is a selected list of papers relating to the subject discussed.

The statistical data are drawn mainly from the reports of the U. S. Geological Survey. The chapter on fertilizers deals with the occurrence, nature, and uses of phosphates, guano, and greensand. The chapter on soils and road materials discusses the origin and properties of soils, especially residual and transported soils, and the distribution of soils in the United States, and very briefly considers the various available road materials in the United States.

Nitrification of nitrogenous matter in the soil, G. MASONI (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 1 (1904), No. 2–3, pp. 265–269; abs. in Centbl. Bakt. [etc.],*

2. Abt., *15* (*1906*), *No. 21*, *p. 643*).—Experiments with poudrette are reported which show that nitrification went on rapidly at first, but that later when the soil became drier and warmer denitrification set up. The bacteriological side of the question is not considered, but the relation of the use of poudrette to the development of smut in corn is discussed.

A study of nitrification of some organic fertilizers, GUILLIN (*Bul. Soc. Nat. Agr. France, 66* (*1906*), *No. 1*, *pp. 85–94*, *fig. 1*).—Studies of relative rate of nitrification in soil and comparative fertilizing value in pot experiments with oats are reported for dried blood, wool waste, roasted wool, crude ammonia obtained from evaporation of ammoniacal gas liquor, wine lees, and "galalith," a refuse from the preparation of various small articles from hardened casein. The amounts of organic nitrogen transformed into nitric nitrogen during 3 months when the different materials were mixed with a suitable soil at rates furnishing 1 gm. of nitrogen per kilogram of soil are shown in the following table:

Nitric nitrogen formed during three months with different organic fertilizers furnishing 1 gm. of nitrogen.

	At end of one month.	At end of three months.	At end of five months.
	Grams.	*Grams.*	*Grams.*
Dried blood	0.168	0.345	0.634
Galalith	.005	.217	.600
Wool waste	.019	.230	.373
Roasted wool	.090	.309	.536
Crude ammonia	....	.014	.199
Wine lees	.051	.070	.086

The dried blood nitrified most readily. The galalith nitrified very slowly at first, but afterwards more readily. The wool waste was much inferior to the roasted wool as regards rate of nitrification. The crude ammonia nitrified very slowly during the earlier stages of the experiment, but with a higher temperature nitrification was quite rapid. The nitrification of the wine lees was very unsatisfactory. The order of efficiency of the different fertilizers in pot experiments with oats was as follows: Dried blood, roasted wool, galalith, wool waste, wine lees, crude ammonia.

In discussing these experiments, A. C. Girard called attention to the fact that this method of comparing fertilizers was inaugurated by Müntz and Girard more than 15 years ago and that it has been shown to be a valuable method of determining the relative value of organic nitrogenous fertilizers.

On the importance of nitrification for cultivated plants, W. KRÜGER (*Landw. Jahrb.*, *34* (*1905*), *No. 5*, *pp. 761–782*, *pls. 3*; *abs. in Chem. Centbl.*, *1906*, *I*, *No. 1*, *pp. 71*, *72*).—The general object of the experiments here reported was to determine whether ammonia is directly assimilated by cultivated plants or whether it must first be transformed by nitrification.

The experiments, which were begun in 1899, were made in pots containing a mixture of 50 per cent sand and 50 per cent ordinary farm soil. One series of pots was sterilized and another was not sterilized. They all received the same basal application of phosphoric acid and lime. Some in each series received no nitrogen, some nitrogen in the form of ammonium salts, and others nitrogen in form of nitrate of soda. The crops experimented with included mustard, oats, barley, potatoes, and fodder beets. The data recorded include the yields and nitrogen content of the plants, as well as qualitative tests of water extracts of the soils.

The results show that mustard, oats, and barley derive nitrogen from ammonium salts and nitrates with equal facility, and that for such crops these two sources of nitrogen are equally valuable. Potatoes appear to prefer ammonia to nitrate as a

source of nitrogen. At least, the action of the first is in no way inferior to that of the second. Beets are much more responsive to applications of nitrate than ammonia nitrogen, and their growth is especially promoted by applications of nitrate.

It appears from these facts that the inferior action of ammonia nitrogen sometimes observed in practice may not be due to inherent superiority of nitrate, but to unlike physiological and other conditions which interfere with the biological processes in the soil. In almost all of the sterilized pots the application of soluble forms of nitrogen gave smaller yields or no increase of yield as compared with pots receiving no nitrogen. This result is also attributed to interference with biological processes. Cultivated plants not only utilize ammonia nitrogen but generally assimilate it to the same extent as nitrate nitrogen. Nitrification is therefore not so necessary for the growth of cultivated plants as is generally supposed. Beets and potatoes represent extremes in this respect among the plants experimented with. The results in general do not warrant the changing of recommendations based on the importance of nitrification, since this process is useful in rendering insoluble soil nitrogen available for plants.

The influence of fertilizing and of plant growth on soil properties and soil exhaustion, W. Krüger (*Landw. Jahrb., 34 (1905), No. 5, pp. 783–804, pl. 1, dgms. 2; abs. in Chem. Centbl., 1906, I, No. 1, p. 72*).—In connection with the study of nitrification noted above, it was observed that the soils receiving different treatments were very variable with reference to their behavior when shaken up with water and allowed to settle, and that their content of soluble lime and magnesia, as well as the proportions of these constituents which were precipitated when sodium carbonate and hydrate were added in the tests for ammonia, varied within wide limits.

The experiments here reported were designed to further study the nature and cause of these variations. They were made in pots each containing 6 kg. of the same soil mixture used in the nitrification experiments, to which there were added in different cases, in addition to the basal fertilizer of phosphoric acid and lime, ammonium sulphate (furnishing 2 gm. of nitrogen), potassium nitrate (14.4 gm.), and sodium nitrate (12.1 gm.), chlorid (8.4 gm.), sulphate (10.1 gm., water-free), carbonate (7.6 gm.), and hydrate (5.7 gm.).

Series of experiments were made with potatoes, mustard, oats, barley, and fodder beets. It was observed in all cases, though more marked with some crops than with others, that the application of nitrate of soda reduced the porosity of the soil, increased the tendency to puddle, and interfered with settling when the soil was shaken with water and allowed to stand. It also increased the tendency to form crusts and clods. These results are attributed to the accumulation of soda in the soil, with consequent formation of sodium carbonate. The application of ammonium sulphate resulted in an increase in solubility of lime and magnesia compounds in the soil. Sodium salts, especially sodium carbonate, reduce the solubility of these substances.

Fixation of atmospheric nitrogen by plants, Trabut (*Bul. Agr. Algérie et Tunisie, 11 (1905), Nos. 23, pp 513–516; 24, pp. 537–547, fig. 1*).—This is a general discussion of the subject, summarizing the more practical results of investigations on the fixation of nitrogen by leguminous plants and the various methods of soil inoculation to promote such fixation which have been proposed.

The utilization of atmospheric nitrogen by means of micro-organisms, R. Thiele (*Landw. Vers. Stat., 63 (1905), No. 3–4, pp. 161–238, figs. 5; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 520, II, p. 114*).—This article reviews the present knowledge relating to Azotobacter, and reports a series of studies of the behavior of the organism in various liquid and solid media; the occurrence of Azotobacter in different soils and its culture in sterile soil; the variation in the nitrogen content of field

soils and its determination (see E. S. R., 17, p. 436), and the optimum temperature for Azotobacter as compared with soil temperatures.

The results, which are reported in detail, show that while there is no doubt as to the power of Azotobacter to fix nitrogen under laboratory conditions, it is not certain that this is a specific characteristic like the power of yeast to produce alcohol. It is thought possible that when the organism is supplied with a large amount of organic matter containing nitrogen its nitrogen-fixing power may be destroyed, and, like yeast when grown in peptone media, may show very different properties from those ordinarily in evidence.

The growth of Azotobacter in artificial media is not therefore to be considered unique or typical. The mode of operation of the organism in the soil is very imperfectly understood and can not be thoroughly cleared up until more accurate methods of determining the very small variations in nitrogen content of the soil which are involved in studies of this kind are secured. Moreover, the temperature conditions in laboratory cultures do not obtain in the natural soil, and therefore the optimum conditions for activity of the organism are not always present. In view of the fact that the life and the work of Azotobacter are still to a large extent unsolved problems, the practical man is not warranted in expecting that Azotobacter fertilizing will in the near future take the place to any extent of applications of nitrate of soda.

Numerous references to the literature of the subject are given and the methods and apparatus used in the experiments reported are described.

The assimilation of free elementary nitrogen by micro-organisms, J. VOGEL (*Centbl. Bakt.* [*etc.*], *2. Abt.*, *15* (*1905*), *Nos. 2-3*, *pp. 33-53; 4-6*, *pp. 174-188; 7-8*, *pp. 215-227*).—A review is given of the more important investigations on this subject, bringing out especially how chemical treatment of the soil and use of fertilizers may retard or promote the activity of different groups of these organisms. A bibliography of the subject containing 148 references is given.

Nitrogen-fixing bacteria, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt.*, *13* (*1905*), *pp. 343-346*, *pls. 3*).—The history of investigation on this subject is briefly reviewed, and experiments on beans, peas, vetches, and red clover with the inoculating material prepared by this Department are reported.

"The results proved (1) that on land which will already produce a good crop of legumes the inoculation is of little benefit to the crop treated, but (2) it increases the number of nodules on the roots and consequently the quantity of nitrogen left in the soil for the benefit of a following crop, such as grain or roots, which have not the power of providing nitrogen for themselves; (3) the inoculated seed invariably gave better results than the inoculated soil."

The relative merits of inoculation by means of infected soil and by pure cultures are discussed and directions and precautions to be observed in the use of inoculating material are given.

Cooperative experiments with nodule-forming bacteria, F. C. HARRISON and B. BARLOW (*Ontario Agr. Col. and Expt. Farm Bul. 148*, *pp. 19*, *figs. 7*).—This bulletin contains brief statements regarding the history of the discovery of these organisms and summarizes the results of tests made by farmers in different parts of Canada of liquid cultures distributed by the Agricultural College at Guelph.

The cultures were sent out in small bottles in such condition that all the farmer had to do was to mix the contents of the bottle with a measured quantity of water and then apply to his seed. Cultures for alfalfa, alsike clover, red clover, white clover, soy beans, vetches, peas, and beans were distributed. Of the 134 reports received, 91 showed benefit from inoculation, 40 no advantage, and 3 stated that the organisms were already present in the soil. Extracts from the individual reports are given as well as detailed directions for using the cultures.

Tests of commercial cultures of nitrogen-fixing bacteria (*U. S. Dept. Agr.*, *Office Sec. Circ. 16*, *folio*).—This circular calls attention briefly to the limitations of

the value of inoculation, and reports the results of tests of 19 samples of cultures of nitrogen-fixing bacteria obtained in the open market. These results show that a large proportion of these cultures were either of poor quality or worthless.

The fertilizing value of atmospheric nitrogen preparations, M. HOFFMANN (*Mitt. Deut. Landw. Gesell., 21 (1906), No. 6, pp. 43–46*).—A summary is given of information relating to methods of preparing and the fertilizing value of "N" fertilizer, lime niter, lime nitrogen, and similar compounds, prepared by various processes from the nitrogen of the air.

Some experiments with lime nitrogen on mineral and moor soils and investigations on the decomposition of calcium cyanamid in various kinds of soil, H. VON FEILITZEN (*Verhandl. Gesell. Deut. Naturf. u. Aerzte, 76 (1904), II, 1. Abt., pp. 157–159; abs. in Chem. Centbl., 1906, I, No. 7, pp. 584, 585; Centbl. Agr. Chem., 35 (1906), No. 2, p. 137*).—The substance of this paper has been noted from another source (E. S. R., 17, p. 17).

Barnyard manure, A. VIVIEN (*Monit. Sci., 4. ser., 19 (1905), No. 2, pp. 773–779; abs. in Chem. Centbl., 1905, II, No. 20, p. 1507*).—The results of studies of the influence of various substances, such as gypsum (2 per cent), chalk (2 per cent), starch (2 per cent), lime refuse from beet-sugar manufacture (3 per cent), formol (0.5 per cent), superphosphate (2 per cent), iron sulphate (1 per cent), sulphuric acid (0.5 per cent), roasted pyrites, mineral phosphates, nitrate of soda (1 per cent), etc., on the transformation of nitrogen compounds in manure are reported.

The smallest loss of ammonia was observed in case of gypsum. Superphosphate, iron sulphate, and sulphuric acid were less effective than was expected. The greatest losses occurred in untreated manure and in that to which chalk and lime refuse were added. In untreated manure and in that treated with mineral phosphate, roasted pyrites, sulphuric acid, crude potash, starch, and formol considerable amounts of nitrate were formed; in manure treated with superphosphate, iron sulphate, gypsum, chalk, and lime refuse only traces were found, and when sodium nitrate was added it was largely decomposed and lost.

The loss of dry matter in manure kept for 3 months in casks varied from 18.22 to 38.13 per cent, and of total nitrogen from 12.07 to 23.72 per cent, except in case of manure to which sodium nitrate was added, in which the loss was 31.21 per cent. The use of acid substances did not reduce the loss. The ammonia thus fixed was apparently easily nitrified and later denitrified and lost.

Litter and nitrogen, R. HORNBERGER (*Ztschr. Forst u. Jagdw., 37 (1905), p. 71; abs. in Centbl. Agr. Chem., 34 (1905), No. 11, pp. 726, 727*).—Pot experiments with leaves of various kinds to test the accuracy of Henry's conclusion (E. S. R., 16, p. 444) that dead forest leaves have the power of fixing appreciable amounts of atmospheric nitrogen are reported. The experiments extended over a year, and in only 2 cases out of 7 was there any gain of nitrogen. The results therefore do not confirm Henry's conclusion.

Crude ammonia, GUERRAPAIN (*Bul. Agr. Algérie et Tunisie, 11 (1905), No. 22, pp. 506–509*).—The origin, character, and agricultural uses of a by-product obtained in the manufacture of gas by passing the impure gas through a mixture of lime, iron sulphate, and sawdust, the mixture afterwards being dried and known as crude ammonia, are briefly discussed.

The material is shown to contain from 4 to 10 per cent nitrogen in form of ammonium sulphate and of cyanids. It is of value as a fertilizer, but on account of the poisonous cyanids and sulphur compounds present it must be applied some time—3 or 4 months—before seeding, in order to secure thorough oxidation of the poisonous compounds. It has been used successfully on sugar beets in amounts furnishing 75 to 100 kg. of nitrogen per hectare.

The material is said to have considerable value as a weed exterminator and insecticide, especially for grape phylloxera, when used at rates of 1,200 to 3,000 kg. per hectare.

Crude ammonia, A. GRAU (*Jour. Agr. Prat., n. ser., 11 (1906), No. 3, pp. 78–80*).—The agricultural value of this product (see preceding note) is discussed and directions given for its use.

Analyses are reported which show a variation in total nitrogen content of 3 to 7 per cent. Tests which have been made of it show that it gives best results on light soils in which nitrification is most active. It is safest to apply it in December or January on land that is to be seeded in the spring. It gives good results on beets and potatoes when applied at rates of 1,000 to 1,200 kg. per hectare, and on oats at rates of 500 to 600 kg. and lightly harrowed in.

Analysis of nitrate of soda, R. BENSEMANN (*Ztschr. Angew. Chem., 18 (1905), No. 50, pp. 1972–1974*).—The author sets forth in complete and orderly form his method of examining this substance, which has been given in a number of previous articles (E. S. R., 17, pp. 7, 218).

Acid versus basic phosphatic fertilizers, W. F. SUTHERST (*Chem. News, 92 (1905), No. 2403, pp. 274, 275*).—It is stated that when superphosphate is added to a soil containing excess of lime phosphates are formed which are insoluble in water but soluble in dilute organic acids, and if alumina and oxid of iron are in excess of lime a still further reversion to insoluble forms results.

When basic slag, however, is used a reverse reaction occurs. For this reason, therefore, the author concludes that basic slag should be a more valuable fertilizer generally than superphosphate, although slower in action because it is not so perfectly distributed as the reverted superphosphate. Comparative tests of superphosphate, basic slag, and basic superphosphate (superphosphate supersaturated with lime) on mangolds are briefly reported, showing that the increased yield with the basic phosphates was greater than with the superphosphate.

On the fertilizing action of certain accessory compounds in slags, GUFFROY, CRÉPEAUX, and MILON (*Rev. Gén. Agron., 14 (1905), No. 10–11, pp. 461–464; Bul. Soc. Nat. Agr. France, 65 (1905), No. 6, pp. 479–483*).—A series of pot experiments is reported which were designed to determine especially the fertilizing value of the silica and manganese occurring in phosphatic slags.

Comparative tests were made with wheat, buckwheat, and clover of ordinary Thomas slag containing 8.41 per cent of silica and 3.87 per cent of manganese oxid, and of carefully separated crystals of tetraphosphate and of silicophosphate, using the latter either alone or with the addition of substances necessary to approximate the composition of natural slag. The amount of complete artificial slag furnishing 78.1 gm. of phosphoric acid (the amount used in each experiment) contained 42.05 gm. of silica and 19.35 gm. of manganese. The low-silica slag, furnishing the same amount of phosphoric acid, contained 4.72 gm. of silica, and the low-manganese slag 7.17 gm. of manganese.

The results show that in case of buckwheat the absence of silica retarded maturity and reduced the yield of straw as well as the weight of the floral envelopes and branches. In case of wheat the absence of silica resulted in retarding the heading and flowering, but was apparently without effect upon the yield. The effect upon strength of straw was not appreciable. The growth and yield of clover were appreciably reduced in absence of silica in the fertilizer. The absence of manganese from the fertilizer produced results similar to those obtained in case of silica as regards the growth and yield of buckwheat, except that they were less marked. The anatomical structure of the plant, however, was affected to a greater extent by the absence of manganese than of silica. Like results were obtained with wheat and clover.

The results in general, therefore, show that the silica and manganese contained in Thomas slag are of considerable importance as fertilizers. On the other hand there was apparently some superiority of the phosphoric acid of the tetraphosphate over that of the silicophosphate, but this is to be further studied.

Comparative experiments with high percentage and low percentage Thomas slag (*Deut. Landw. Presse, 32 (1905), No. 79, pp. 667–669, figs. 4*).—Plat experiments with rye and oats, using equal money values of the two slags (the low-percentage slags containing not more than 5 per cent of citric-acid soluble phosphoric acid), showed the high-percentage phosphate to be more economical. See also E. S. R., 16, p. 1064.

Citric-acid soluble phosphoric acid in Thomas slag, M. DE MOLINARI and O. LIGOT (*Bul. Agr. [Brussels], 24 (1905), No. 5, pp. 909–916; 6, pp. 1116–1118*).—Comparative pot tests of untreated Thomas slag and that which had been exhausted with citric acid according to the Wagner method are reported. The results show that the yield of oats was normal with the untreated slag but practically nil with the extracted slag.

Phosphate mining in Tennessee, D. S. COOKE (*Amer. Fert., 23 (1905), No. 5, pp. 5–10, figs. 8*).—This article discusses the rapid growth of this industry, some of the difficulties encountered in developing it, the peculiarities of laborers, and the present outlook.

Algerian phosphate and apatite (*Mitt. Deut. Landw. Gesell., 20 (1905), No. 46, pp. 389–391*).—This is a summary of experiments by Söderbaum in Sweden, comparing the composition and fertilizing value of Algerian phosphate and Norwegian apatite when applied to oats grown on sandy soils and peas grown on moor soils. The results show in general the superiority of the Algerian phosphate.

Experiments on the assimilation of potash and soda by plants, T. PFEIFFER ET AL. (*Mitt. Landw. Inst. Breslau, 3 (1905), No. 4, pp. 567–613; abs. in Chem. Ztg., 30 (1906), No. 10, Repert. No. 2, pp. 25, 26*).—The numerous investigations on this subject which have been made in recent years are referred to.

A series of pot experiments made during 1903 and 1904 on barley with potash-containing and potash-free artificial zeolites (potassium, sodium, and calcium zeolites) is reported, the object of the experiments being to study the capacity of plants to utilize the potash of such compounds, the influence of potash-free zeolites on the utilization and the fixation of the potash salts applied with them, and the extent to which applications of sodium salts overcome the unfavorable action of potash-free zeolites. The zeolites and necessary basal fertilizers were applied to pots containing 4 kg. of sand. The yield and potash and soda contents of the total crop, straw, and grain are recorded.

The results show that the potash of zeolites was readily utilized by the plant (as high as 88 per cent). The potash content of the grain remained fairly constant, but that of the straw varied widely with the amount of potash available for the uses of the plant. The action of potash fertilizers was somewhat reduced by applying them in connection with sodium and calcium zeolites, thus indicating some fixation of the potash in less available forms. Increasing the applications of potash lowered the sodium content of the plants. Incidentally it was observed that sand which had been treated with soda solution and hydrochloric acid yielded more potash and soda to the plants than that which had not been treated.

The indirect action of soda on the utilization of potash, which the experiments indicate, is ascribed to an exchange of bases. In case of soils rich in potash this exchange of bases may result in a sufficient supply of potash to crops for a number of years. It is, however, a species of soil robbery and will ultimately result in potash exhaustion. The same is true of the continuous use of potash salts rich in sodium chlorid, although in this case exhaustion is not so rapidly brought about.

Sodium salts act in two ways, (1) by setting free potash in the soil, and (2) by replacing potash in plants. In case of a crop like barley, the need of the grain for potash is first supplied, and if there is a deficency of potash for the whole plant soda replaces the potash in the leaves and stalks, thus making the potash available for the uses of the grain. It appears, therefore, that sodium salts enable the plant to make the best possible use of a given amount of potash in the production of grain.

The author concludes in general that applications of sodium salts in connection with potassium salts result in a greater assimilation of potash, which is shown in a greater total production in the case of barley in which the grain does not participate except to the extent that a part of the potash of the stems and leaves is replaced by soda, leaving the potash available for the production of the grain.

It is suggested that the plant food value of the elements may be a periodic function of their atomic weights and that elements like potassium of the medium atomic weights may be termed phyto-chemic.

Manuring with potash salts, C. DUSSERRE (*Chron. Agr. Vaud, 18 (1905), No. 23, pp. 567–575, fig. 1*).—A brief account is given of experiments which have been carried on at a number of places in Lausanne since 1898 to determine the value of potash salts as fertilizer for grass lands.

Soils of widely different geological origin and mechanical and chemical composition were used in these experiments. The total content of potash in the soils varied from 7.9 gm. per kilogram of fine earth in a peaty soil to 22.2 gm. in an alluvial soil. The soluble potash varied from 0.4 gm. in an alluvial soil to 1.28 gm. in an erratic clay soil. There was apparently no strict relation between the total and soluble content of potash in the soil and the effect of the potash salts, although the potash fertilizers were in general beneficial in the Jurassic formations, which are as a rule poor in potash, while in crystalline (granite) formations or in crystalline schists (gneiss), in which potash is abundant, the use of potash fertilizers produced less effect.

The results in general indicate that through a series of years the use of potash salts was profitable on all the soils experimented with. The liberal use of phosphatic, nitrogenous, and calcareous fertilizers for a number of years renders the use of potash fertilizers necessary. The amount of assimilable potash in the soil becomes exhausted, and the amount which the soil yields to the plant is not sufficient to meet the demands of the large crops produced by the use of the other fertilizers. The crops which especially require applications of potash are beets, potatoes, tobacco, forage plants, etc.

Kainit, L. BARGERON (*Jour. Agr. Prat., n. ser., 10 (1905), No. 48, pp. 688–690*).—The various salts included under this general name in France, as well as potash salts from other sources, such as sea-weed ashes, sea water, etc., are briefly discussed.

A molasses-potash fertilizer, O. REITMAIR (*Separate from Wiener Landw. Ztg., 1905, No. 94, pp. 8*).—This article briefly discusses the fertilizing value of the material obtained by drying or by burning the residue from the distillation of molasses. The dry product has been put on the market under the name of chilinit, which contains considerable amounts of nitrogen as well as potash. The burned product contains a higher percentage of potash but no nitrogen, but is very variable in composition.

On the successful use of manganese as a fertilizer, G. BERTRAND (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 26, pp. 1255–1257; Jour. Agr. Prat., n. ser., 11 (1906), No. 2, pp. 42, 43*).—The author refers to his work on laccase as convincing him of the physiological importance of manganese, and quotes the work of several other investigators as confirming his conclusions. He reports field experiments with oats on two plats both of which received the same basal fertilizer, but only one was fertilized with manganese sulphate at the rate of 50 kg. per hectare (44.53 lbs. per acre).

There was an increase on the plat receiving manganese of 22.5 per cent in total crop, 17.4 per cent in grain, and 26 per cent in straw. The grain from the manganese plat was somewhat heavier than that from the other and contained somewhat less water, but was otherwise of practically the same composition. The percentage of manganese present in the grain was very minute.

The recovery of products of commercial value from sewage sludge, J. GROSSMANN (*Jour. Soc. Chem. Indus., 24 (1905), No. 12, pp. 655-659*).—A plant constructed at Bradford in Yorkshire, on plans prepared by the author, for the distillation of sewage sludge is described and the principles upon which plants should be constructed and operated are discussed. These in brief are as follows:

"(1) The sludge should be heated in comparatively thin layers. . . . (2) The furnaces should be capable of maintaining an even heat at temperatures varying from 200° to 500° C., or even more. (3) Manual labor should be dispensed with as far as possible by the substitution of mechanical appliances by which the process could be made continuous, and almost automatic. (4) Under these circumstances it would be impracticable to maintain a high vacuum, but a slight minus pressure in conjunction with superheated steam would be most likely to give satisfactory results."

The products obtained in this plant, the cost of installation of which was about $20,000, and which required 2 tons of coke per day, are "7 tons of residue, containing besides free carbon about 2 per cent of nitrogen, corresponding to 8 per cent of ammonia sulphate and 1 per cent of phosphoric acid, equal to a little over 2 per cent of calcium phosphate, and a quantity of grease which depends on the original quantity contained in the sludge." Means of increasing the salable products are discussed.

Plant analysis as an aid in estimating the manurial requirements, with special reference to hops, P. SCHNEIDER (*Wchnschr. Brau., 22 (1905), pp. 456-458; abs. in Chem. Centbl., 1905, II, pp. 970, 971; Jour. Chem. Soc.* [*London*], *88 (1905), No. 517, II, p. 755*).—The analyses made by the author show that the more advanced leaves of hops showed a definite minimum of phosphoric acid when this substance was deficient in the soil. This was most evident at time of the first crop in the lower leaves, but at time of the second crop in the upper leaves. The nitrogen followed the same course as that of phosphoric acid and was best detected by analysis of the leaves. No definite results, however, could be obtained in the case of potassium, magnesium, and calcium.

Analysis of commercial fertilizers sold in Maryland, H. B. MCDONNELL ET AL. (*Md. Agr. Col. Quart., 1905, No. 29, pp. 64*).—This is a report on fertilizer inspection during the period from March to June, 1905, inclusive.

Inspection of fertilizers in 1905, F. W. MORSE ET AL. (*New Hampshire Sta. Bul. 123, pp. 133-144*).—This bulletin gives the results of analyses of 105 brands of mixed fertilizers collected by the State board of agriculture and analyzed by the chemist of the station. It also contains a short article on the use of commercial fertilizers. Among the samples inspected "there were 27 cases of failure to equal the guarantee in one or more ingredients, but in all but 9 of them a lack in one element was made good by an excess of another without affecting the value of the goods. The majority of deficits was found in available phosphoric acid in the lower grades of goods."

AGRICULTURAL BOTANY.

Calcium as a plant nutrient, V. V. YERMAKOV (*Zhur. Opuitn. Agron.* (*Russ. Jour. Expt. Landw.*), *6 (1905), No. 1, pp. 63-65*).—The author carried on a series of experiments in light and darkness with seedlings of buckwheat, blue lupines, and detached leaves of various plants, to test the effect of calcium as a plant nutrient.

Seedlings were placed in normal nutritive solutions containing calcium salts and in solutions without calcium salts, and afterwards the plants were examined for the

presence of nitrates. Nitrates were observed in the cotyledons and also in the hypocotyl, the plants receiving the normal solutions containing nitrates only in the hypocotyl, and those which received no lime containing nitrates both in the hypocotyl and the cotyledons.

From his experiments the author concludes that the absence of nitrates in the cotyledons of normal plants indicates the formation of organic nitrogenous material at the expense of the nitrates, while in plants grown without calcium nitrates are not assimilated. The author tested the results in various ways, and concludes that the presence of lime in a nutritive solution is necessary for the assimilation of nitric-acid salts by plants, whether grown in darkness or in light.—P. FIREMAN.

Regeneration in plants, W. B. MCCALLUM (*Bot. Gaz., 40 (1905), Nos. 2, pp. 97–120, figs. 14; 4, pp. 241–263, figs. 9*).—A study was made of the influence of different factors on the regeneration of parts of plants, the principal investigations being made with bean seedlings. The influencing factors studied were wound stimuli, disturbance in nutrition, changes in water content, accumulation of formative substances, age and degree of maturity, correlation, and growth tension.

Summarizing his investigations, the author shows that the occurrence of regeneration in plants usually involves the replacement of the organs removed, but the same result is often obtained when the organ itself is not removed but is prevented from functioning. The plant possesses innumerable growing points, the majority of which do not develop if the plant body retains anything like a definite organization. In most cases this development does not occur, because these cells capable of producing new organs are held in check by those parts already growing. This nondevelopment does not seem to be due to any lack of conditions of favorable growth, but is due to some influence which an organ, acting perhaps along the protoplasmic connections, is able to exert over other parts and so prevent their growth. When this influence is removed, the favorable growth conditions present permit the growth of the parts to occur.

A bibliography of literature relating to this subject is appended.

The rôle of the albuminoid substances of leaves and their accumulation in ripening seeds, N. I. VASILYEV (*Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 4, pp. 385–400*).—In a previous article (E. S. R., 16, p. 746) the author expressed the view that the ripening process of seeds is the inverse of the process of germination, and he assumed that the albuminoid substances produced in the leaves are transported to the seeds, in which they are again transformed into albumin.

In the present investigation the author examined the leaves of the white lupine during various periods of ripening of the seeds, analyzing separately the petioles and the leaf blades. It was found that with the advanced development of the plants and the increasing ripeness of the seeds the amount of total nitrogen and of albuminoid nitrogen in the leaves decreased, while corresponding amounts of nitrogen increased in the seeds.

An examination of the distribution of the different groups of nitrogenous substances in the leaves and their petioles showed that the leaves are richer in total and albuminous nitrogen than the petioles. The petioles, on the other hand, are richer in nonalbuminoid nitrogen and especially in asparagin.

The author concludes that in leaves the nitrogenous substances are synthesized to albumin, and then remain in this form indefinitely as reserve substances. At the time of the formation of the seeds and during their ripening the leaves begin to deliver their reserve albuminous substances to the seeds. The reserve albumin, splitting up, is transported to the seeds in the form of such nitrogenous compounds as amido acids, asparagin, and organic bases.—P. FIREMAN.

The physiological anatomy of the root tubercles of some Leguminosæ, J. BERNATSKY (*Math. u. Naturw. Ber. Ungarn, 20 (1902), pp. 65–70, figs. 5*).—In this paper (not printed until 1905) the author reports a study of the anatomy of the

root tubercles of *Robinia pseudacacia*, *Tetragonolobus siliquosus*, and several species of Cytisus, Orobus, and Vicia, and he claims in every case to have determined the possibility of gas exchange through the cortex of the roots.

The effect of self-fertilization in the Leguminosæ, O. KIRCHNER (*Naturw. Ztschr. Land u. Forstw., 3 (1905), Nos. 1, pp. 1-16; 2, pp. 49-64; 3, pp. 97-111*).—Observations are given on the self-fertilization of about 100 species of Leguminosæ, representing 34 genera, the data in many instances being compiled from various sources, and in a number of cases the statements were confirmed by the author. About one-third of the species are reported as being self-sterile.

The effect of light on Melilotus alba, R. W. COPPEDGE (*Trans. Kans. Acad. Sci., 20 (1905), pt. 1, pp. 97-105*).—The author describes a number of experiments to test the effect of light on sweet clover, studying its effect on the nutation of leaves and stems, the relation between movement and strength of light, the relation between light and carbon dioxid gas in forming starch, and the time at which starch was formed and disappeared in the plant.

In studying the nutation of the leaves and stems, the author found that the hot-sun position assumed by the plant depends on the amount of moisture in the soil and not on the condition of the atmosphere, and that the opening and closing of the stomata depend on the relative humidity of the atmosphere. Nutation he found to take place in almost the entire stem of the young plant, being most noticeable in the pulvinus and decreasing toward the roots. As the plant grows older the region of nutation is diminished.

Experiments to determine whether the movement of the plants and leaves depended on the light only showed that light alone was the cause of the normal day movements of the plants, and the rate of movement was found to depend on the strength of the light.

In determining the relationship between light and carbon dioxid in starch formation the author experimented with leaves in different temperatures, in different colored lights, etc., and found that only in the presence of both light and air was starch formed and that it disappeared from the leaf when air only was present.

The experiments as to the time when the starch left the plant indicated that there was a gradual decrease of starch after midnight, with its reappearance in the morning. In one series of experiments all the starch had disappeared at 5 o'clock in the morning. In another series leaves were examined every half hour, beginning at 4 o'clock in the morning, and at this time the cells were crowded with starch. At 4.30 most of the starch had gone from the palisade cells; at 5 o'clock it was present only in the sieve-tubes, and a little in the cells bordering them; and at 5.30 all the starch had gone from the leaf. At 6 o'clock starch began to appear again in the palisade cells, showing that it disappears first from these cells and also reappears first in the palisade tissues.

The action of sulphur dioxid on plants, A. WIELER (*Untersuchungen über die Einwirkung schwefliger Saure auf die Pflanzen Berlin: Borntraeger Bro., 1905, pp. VII + 427; rev. in Nature [London], 73 (1906), No. 1895, pp. 385, 386*).—A monograph dealing with the injurious action of sulphur dioxid on plants, especially on forest trees.

About one-half of the volume is taken up with accounts of experimental examination of the action of the gas on plants, after which the demonstration of its action on leaves and proof that it enters through the stomata are given, together with accounts of its action on the soil, relation between height of trees and constitution of soil, resistance of plants to the gas, and the amount of gas in the air of contaminated regions.

It is claimed that sulphur dioxid was found in the leaves of all plants examined as far as 8 kilometers from any known source of pollution, but there was no relation between the degree of injury and the concentration of the poison in the air, nor could any

clear connection be detected between the quantity of sulphur dioxid in the leaves and the distance of these from the centers of contamination.

The author finds that the gas penetrates into the leaves solely through the stomata, a fact that has been disputed by a number of writers. He distinguishes between acute and chronic affection of plants, the former being due to the corrosive action of high percentages of sulphur dioxid within a short period, and the latter to the slow action of low percentages within a longer one. The author directs attention particularly to the latter class of injury. Different plants were found to react in a very dissimilar manner and to be unequally sensitive, and the author points out that it is necessary to distinguish between sensitiveness of organs and the resistance of a plant as a whole.

It is claimed that sulphur dioxid was found to adversely affect photosynthesis, but no critical concentrations could be established for different species. An inductive action of the poison was frequently noticed, by which it was shown that there was a direct action of the gas on the chloroplastids. In addition to corrosions due to acute affection, the characteristic effects of a chronic nature were observed to be precocious autumnal coloration and fall of the leaves and effects similar to these resulting from partial starvation. The author discusses the mode of action of the poison on plants, and believes that it unites particularly with the aldehydes present and that sulphuric acid is liberated, the injury being due to this acid.

The general features of chronically injured trees are said to be strikingly similar to those due to defective nutrition, and the author attributes the effects to the indirect action of sulphur dioxid on the soil, resulting in the removal of basic constituents and the consequent acidification due to humic acids. As a remedy for chronic injury the application of manures, especially basic ones, such as lime, is recommended.

The probable bacterial origin of the gum of linseed mucilage, R. G. SMITH (*Proc. Linn. Soc. N. S. Wales, 30 (1905), pt. 1, pp. 161–174*).—The production of gum or slime in plants by bacteria is believed to be abnormal in the case of sugar cane, various Leguminosæ, etc., but in the case of linden, flax, and quince, gum and mucilage are of such common occurrence that it is not so easy to believe that the origin may be bacterial. The author has examined the tissues of lime, quince, and flax bacteriologically, and in all cases has found slime-forming bacteria. It is a matter of common information that the seed of flax contains practically no starch, and that the digestible carbohydrates consist chiefly in mucilage.

In the present paper the auther gives an account of his studies with flax, and concludes that the gums of flax mucilages vary in their chemical reactions and are probably of different chemical constitution. The product of hydrolysis consists of galactose and reducing substances which yield indefinite osazones, and which are possibly allied to the furfuroids of Cross, Bevan, and Smith. The gum bacteria in the tissues of Linum are relatively very numerous and consist chiefly of races of 2 species. The chemical reactions of these gums are practically identical with the reactions of flax gum. The gum formed by one species is hydrolyzed to galactose, and the other to galactose and a reducing substance that yields an indefinite osazone.

The gum formed by bacteria is probably altered by the plant into mucilage and other substances required in the plant economy. A number of the so-called species of gum bacteria have probably one common origin, and the host plant can alter the nature of the gum product which influences the growth characters. Two species, *Bacillus lini I* and *B. lini II*, are described as new.

The ascent of water in trees, A. J. EWART (*Phil. Trans. Roy. Soc. London, Ser. B, 198 (1905), pp. 41–85, figs. 5*).—After briefly reviewing some of the theories regarding the ascent of water in trees the author describes his investigations with a number of species of trees and shrubs, and shows the influence of various factors on the conductivity of water.

In summarizing his results the author states that the flow of water through open vessels filled with sap takes place in accordance with Poiseuille's formula for the flow through rigid tubes, any divergences noticed being due to the presence of irregular internal thickenings in the vessels. The length of vessels in the woods examined varied from 7 to 36 cm. The resistance to transverse flow through the wood was found to be from 300 to 45,000 times greater than to longitudinal flow, and the resistance to filtration under pressure, through a single partition wall, in the case of the wood of the crab apple, was from 2 to 10 times greater than that to flow through the entire length of the vessels. The total resistance to flow in erect stems of actively transpiring plants appears to correspond in the case of shrubs and small trees to a head of water of from 6 to 33 times the height of the plant, and in the case of large trees from 5 to 7 times their height. This would require, to maintain active transpiration in tall trees, total pressures equivalent to at least 100 atmospheres.

It appears, therefore, that to maintain the flow a pumping action of some kind must be exercised in the wood, for which the presence of active living cells is essential. In support of this, it has been shown that the production of wood in a slow-growing tree is greater than is necessary for its mechanical requirements. There is no means by which the cells can directly pump water in a definite direction, although the existence of a power of absorbing and exuding water under pressure has been proved in the living wood of cut branches. It is suggested that the wood-parenchyma cells, by the excretion and reabsorption of dissolved materials, may bring into play surface-tension forces within the vessels of sufficient intensity to maintain a steady upward flow and keep the water of the Jamin's chains in the vessel in a mobile condition, ready to flow in whatever direction suction is exercised.

It appears that the terminal branches of trees at heights of from 22 to 44 ft. exhibit little or no power of bleeding in the spring. It is believed possible that in such trees the pumping action is only used or developed in the wood of the older stems, or is only exercised when transpiration is active, and the water columns in the vessels attain a definite size in proportion to the wood-parenchyma cells. The importance of the Jamin's chain in the vessels is that it renders a staircase pumping action possible, and enables the water to be maintained in them in a labile condition, ready to flow to any point where moderate suction is exercised. This pumping action being diffuse and probably regulated need not produce any high pressure of exudation at the terminal branches of tall trees, and, in fact, it appears always absent at high levels.

The artificial nutrition of diseased trees, S. A. Mokrzhetski (*Zeml. Ghaz., 1904, Nos. 9-13; rev. in Zhur. Opuitn. Agron.* (*Russ. Jour. Expt. Landw.*), *6* (*1905*), *No. 1, pp. 82, 83*).—The author conducted a number of experiments in which he introduced arsenic, copper sulphate, eosin, and other poisonous solutions into trees for the purpose of destroying parasites, but did not obtain any very satisfactory results.

He then replaced the poisonous salts by nutritive ones and obtained interesting results in improving the condition of the trees. For the introduction of dry salts into the trunk of the tree holes ½ in. in diameter and 1 in. deep were bored into the trunk at about breast height. Into these holes 1 to 4 gm. of salts was placed and the openings covered with land plaster. For trees not over 3.5 in. one hole was sufficient, but for larger trees 2 to 4 holes were found necessary. For trees with a diameter of 7 to 9 in. 10 to 12 gm. of salts was used. It was found that the earlier in the spring the salts were introduced the better the results.

For different soils and under different conditions of growth the author used fertilizing mixtures recommended by Wagner, Sorauer, and Muller-Thurgau. To the last mixture he found it advantageous to add 1 part iron sulphate, to be used for curing chlorosis. The experiments showed that the dry salts diffused through the trees in different ways, not only along vertical lines but sometimes in spirals. The

introduction of nutritive solutions of varying concentration, while giving positive results, were not found as efficient as dry salts.—P. FIREMAN.

Investigations on the starch and fat content of fir trees, L. FABRICIUS (*Naturw. Ztschr. Land u. Forstw., 3 (1905), No. 4, pp. 137–176, pls. 2*).—Investigations are reported on the fluctuation of the reserve materials in the fir tree at different periods of the year. The trunks and roots of trees of various ages were examined at eight different times during the year and their starch and fat content determined.

Physiological investigations on the reserve material of trees, LECLERC DU SABLON (*Rev. Gén. Bot., 18 (1906), Nos. 205, pp. 5–25, figs. 7; 206, pp. 82–96, figs. 6*).—In a previous publication (E. S. R., 14, p. 1045) an account was given of observations on the reserve carbohydrates in the leaves, stems, and roots of chestnut and other deciduous trees at different times of the year.

In the present memoir the investigations are extended to include trees with persistent foliage, and also to test the effect of decortication on the production and transfer of carbohydrates. Among the evergreen trees studied were the holly oak, Austrian pine, larch, and Japanese and European euonymus, and among the deciduous trees, the pear, quince, etc. In addition to the carbohydrate reserves, observations were made on other reserve materials, water contents, etc.

In the case of trees with persistent foliage the synthesis of carbohydrates takes place with varying degree throughout the year. The reserve supply is drawn upon in the spring of the year when the buds are unfolding and also during periods of intense respiration. As a result the minimum of reserve material occurs during the summer, from which time it increases throughout late summer and winter, attaining the maximum just before the spring budding. With the deciduous species the carbohydrate assimilation takes place only during the summer season, or from April to October, but during that period it is much more vigorous than in the case of evergreens.

The maximum of carbohydrate reserves in both stems and roots coincides with the autumnal fall of the leaves. In the spring of the year when young shoots are being put out rapidly the minimum of the reserve material is noted. The young shoots seem to be largely formed from the stored reserves of the stems and roots, and the abundance of the reserves determines the winter respiration of the tree, as well as the extent of the new spring growth. In all the species studied an increase in the water content of the trees was noticed just at the period of the beginning of growth in the spring, and in general a maximum of carbohydrate reserve material and a minimum of water are coincident. The water content is said to depend more upon the state of growth than on the degree of soil humidity.

Attention is called to the fact that the starch in the carbohydrate reserve material diminishes during winter and shows an increase in the spring of the year, and in general the maximum of carbohydrates is accompanied by a minimum of starch. This is explained by the theory of the transformation of starch into reserve cellulose, which is again changed to a starch or some similar body preparatory to use by the tree.

Contributions to the biology of Rhizobia. IV, Two coast Rhizobia of Vancouver Island, B. C., A. SCHNEIDER (*Bot. Gaz., 40 (1905), No. 2, pp. 135–139, figs. 3*).—The author describes the micro-organisms occurring in the tubercles found on the roots of 2 species of leguminous plants, beach vetch and beach clover, common on Vancouver Island. These forms present quite different morphological characters, and it is thought probable that there are extreme types which are derived from an original form similar to, but not necessarily identical with, that occurring on cassia, black locust, and other species of leguminous plants.

Contributions to the biology of Rhizobia. V, The isolation and cultivation of Rhizobia in artificial media, A. SCHNEIDER (*Bot. Gaz., 40 (1905), No. 4,*

pp. 296–301).—The author has successfully examined, isolated, and cultivated the micro-organisms growing in the root tubercles of red, white, bur, and sweet clover, garden peas, and alfalfa, and the results obtained have been so satisfactory that he gives a detailed account of the methods pursued.

Directions are given for the selection of the tubercles, methods of treatment, and transfer to nutrient media. The author prefers the slightly alkaline solid media of beef extract, salt, gelatin, and agar, only sufficient agar being used to give solidity. The directions for preparing tubes and their inoculation, as well as for plating the contents of the inoculated tubes, are given in detail. One reason for apparent failure in the culture of these organisms is believed to be the fact that the morphological characteristics are entirely changed, so that there is little similarity between the organism as it appears in the tubercle and that appearing in the artificial culture media.

The delta of the Rio Colorado, D. T. MACDOUGAL (*Contrib. N. Y. Bot. Gard., 1906, No. 77, pp. 16, figs. 6, map 1*).—The physical and topographical features of the region are described, after which the author gives lists of the plants found and their uses, and discusses briefly the agricultural possibilities of the region through the extension of irrigation.

The poisonous plants of Indiana, S. COULTER (*Proc. Ind. Acad. Sci., 1904, pp. 51–63*).—A list is given of a large number of species of plants that are reputed to be poisonous by contact, the species being embraced in about 40 genera and many distinct orders of plants. The author has been led to doubt the poisonous action of many of the plants, and he has conducted investigations with fresh material of all of them as far as available, and as a result has greatly reduced the number of plants which are known to be contact poisons.

The poisonous plants may be readily separated into two groups. In one the skin irritation is due to the action of some specific substance of the plant, while in the other it is mainly due to mechanical causes. The method of experimental study was to handle the plants freely, and if after some days no results were apparent, the part of the plant said to contain the poisonous element was rubbed upon the back of the forearm until serum, and at times blood, exuded, the juice of the plant and the serum being allowed to dry upon the arm. If no results followed it was considered safe to infer that the plant was not a contact poison.

Detailed results are given of the investigations of the different species enumerated in the list, and in conclusion the author states that the great majority of the plants included in the list are harmless under ordinary handling. Some may act as skin irritants as the result of prolonged application or unusually rough handling. Careful washing after handling any of the forms will reduce the danger to a minimum.

The species found to be definitely contact poisons, arranged in order of their virulence, are *Rhus vernix*, *R. radicans*, *Euphorbia corollata*, *Cypripedium hirsutum*, *Anthemis cotula*, *Erigeron* [*Leptilon*] *canadense*, *Clematis virginiana*, and *Bidens frondosa*. This list does not include the nettles or a number of forms which poison under unusual conditions, such as grinding, powdering, or long-continued application. Of the plants mentioned above, the two species of the genus Rhus are the only ones which affected all the experimenters. The greater number of the plants experimented with proved absolutely harmless under all conditions of experiment.

FIELD CROPS.

Results obtained in 1905 from trial plats of grain, fodder corn, field roots, and potatoes, W. and C. E. SAUNDERS (*Canada Cent. Expt. Farm Bul. 53, pp. 48*).—The results secured in 1905 in variety tests with the different field crops conducted for the past 11 years on uniform trial plats are given mainly in tabular form. The reports for earlier years have been previously noted (E. S. R., 16, p. 961).

The average yield of 26 varieties of spring wheat tested on all the experimental farms in 1905 was 29 bu. 5 lbs. Of 26 varieties tested for 5 years, Preston and Advance stood first with an average yield of 35 bu. 13 lbs. and 34 bu. 42 lbs., respectively. Twelve of these varieties, including the 2 just mentioned, were crossbred sorts produced on the experimental farms. The average number of days required for the 26 varieties of spring wheat to reach maturity ranged from 111 to 121. The average yield of 4 varieties of macaroni wheat grown on all the farms this season was 31 bu. 37 lbs. per acre. The average yield for 5 years of Roumanian was 37 bu. 55 lbs., and of Goose, 36 bu. 23 lbs. Roumanian ripened in 121 days and Goose in 119. The average yield on all the farms of 4 varieties of emmer and spelt in 1905 was 2,270 lbs. per acre. In average yield for 2 years common emmer stood first with 2,280 lbs. and white spelt last with 1,915 lbs. per acre.

Thirty-nine varieties of oats under test in 1905 yielded on an average at all the farms 83 bu. 6 lbs. per acre. Thirty varieties tested for 5 years showed a range in average yield of from 69 bu. 26 lbs. to 85 bu. 24 lbs. per acre. The most productive varieties, given in the decreasing order of yield, were Banner, Abundance, Lincoln, Danish Island, Improved American, Siberian, Wide Awake, Holstein Prolific, White Giant, Golden Beauty, Golden Tartarian, and Columbus, all yielding over 80 bu. per acre for the 5 years. Of the varieties under test 5 were crossbred sorts produced on the farms.

The average crop of 18 varieties of six-rowed barley for the season was 54 bu. 28 lbs. per acre. Twelve of the varieties under test were crossbred sorts produced on the experimental farms. In average yield for 5 years Mensury stood first with 56 bu. 38 lbs. per acre. Sixteen of the 18 varieties gave a yield per acre of over 50 bu. The average yield of 14 varieties of two-rowed barley in 1905, including 8 crossbred sorts, was 48 bu. 3 lbs. per acre. The average yields for 5 years ranged from 44 bu. 46 lbs. to 51 bu. 2 lbs. per acre, the leading varieties yielding over 50 bu. being, in decreasing order of yield, French Chevalier, Danish Chevalier, and Standwell.

The 26 varieties of peas tested this year gave an average yield of 39 bu. 39 lbs. per acre. Fourteen of the varieties, including 3 in the list yielding over 40 bu. per acre, were crossbred varieties originated on the farms. The leading varieties under test for 5 years, in decreasing order of yield, were Mackay, English Gray, Early Britain, Agnes, and Prince, all yielding over 40 bu. per acre. The average yield for 5 years of the entire list varied from 37 bu. 30 lbs. to 41 bu. 2 lbs. per acre.

Twenty varieties of corn tested on all the farms in 1905 gave an average yield of 21 tons 1,397 lbs. per acre. The highest average yield for 5 years, 22 tons 400 lbs., was produced by Thoroughbred White Flint. Six varieties produced an average yield of over 19 tons per acre for 5 years.

Twenty varieties of turnips gave an average yield of 28 tons 795 lbs. per acre for the season; 16 varieties of mangels, 30 tons 620 lbs.; 10 varieties of carrots, 22 tons 556 lbs.; and 8 varieties of sugar beets, 24 tons 1,284 lbs. per acre. The leading varieties in average yield for 5 years were as follows: *Turnips*—Perfection Swede, Magnum Bonum, and Hall Westbury, all yielding over 32 tons per acre. *Mangels*—Half Long Sugar White, Mammoth Yellow Intermediate, Mammoth Long Red, and Lion Yellow Intermediate, the yield of the first variety being 32 tons 295 lbs. per acre, and that of the other 3 over 31 tons. *Carrots*—Giant White Vosges, New White Intermediate, Ontario Champion, and Mammoth White Intermediate, all yielding over 23 tons per acre. *Sugar beets*—Red Top Sugar and Royal Giant, yielding over 26 tons, and Danish Red Top, yielding over 25 tons per acre.

Forty varieties of potatoes were grown this season on all the experimental farms, and the average yield per acre secured was 444 bu. 16 lbs. The range in average yield of 34 varieties grown for 5 years was from 297 bu. 29 lbs. to 451 bu. 53 lbs. per acre. Nineteen of the varieties gave a yield of over 400 bu. per acre. The leading varieties in average yield for 5 years were Late Puritan, Rose No. 9, Uncle Sam, and Seedling No. 7, all yielding over 430 bu. per acre.

[Field crop work], E. CLIFTON ET AL. (*New Zeal. Dept. Agr., Ann. Rpt., 13 (1905), pp. 228-277, pls. 9*).—Among other work of the New Zealand experiment stations culture tests with various field crops are reported. At the Waerenga Station Connecticut tobacco under shade grew very luxuriantly, the leaves produced being in some instances 1 ft. 10 in. across, well ripened, and of fine texture.

At the Momohaki Station over 100 varieties of potatoes were grown in small plats. The leading variety the last year of the experiments was Northern Star, which yielded over 20 tons per acre, while Imprest Queen ranked first in the average yields for 3 years with more than 19 tons per acre. The boxing of seed potatoes to facilitate planting in backward seasons is described.

The results of fertilizer experiments with Crimson King swede, in which the fertilizers applied represented equal money value, were in favor of 3¼ cwt. of guano per acre, which produced a yield at the rate of 31 tons 3 cwt. Of the smaller applications tested, 2½ cwt. of steamed bone dust per acre gave the best average yields, the results for 9 years showing an average of 28 tons per acre. Notes are also given on the culture of fodder beets and of forage crops.

Annual report on the experimental farms in the Bombay Presidency, 1905 (*Ann. Rpt. Expt. Farms Bombay, 1905, pp. 106*).—Brief reports are given on the work of twelve experimental farms and of the botanical gardens. The experimental work comprised in general culture, variety, and fertilizer tests with millet, Bombay hemp, rice, wheat, cotton, potatoes, and various forage crops, including a number of leguminous plants. A tabular statement showing the field records of a number of hybrid cottons is given.

Department of cooperative experiments, L. H. GODDARD and M. O. BUGBY (*Ohio Sta. Circ. 47, pp. 10*).—The history of cooperative experiments in Ohio is given and a list including the experiments now receiving special attention is presented. The manner in which the work is handled with each individual experimenter is described.

Partial statement of tests offered for 1906 (*Ohio Sta. Circ. 45, pp. 3*).

Proposed constitution and by-laws of the Ohio Plant Breeders' Association (*Ohio Sta. Circ. 46, pp. 3*).

An example of model farming, W. J. SPILLMAN (*U. S. Dept. Agr., Farmers' Bul. 242, pp. 16, figs. 5*).—The subject-matter of this bulletin has been noted from another source (E. S. R., 16, p. 210).

The possibility of diminishing errors in field trials caused by unevenness of soil, G. HOLTSMARK and B. R. LARSEN (*Tidsskr. Landbr. Planteavl, 12 (1905), pp. 330-351*).—In the plan worked out by the author with this purpose in view the field is divided into squares for comparative trials with different varieties, fertilizers, etc.

Every third square is used as a control plat, and in calculating the results the average of the yields on the 3 control plats lying nearest a trial plat is taken into consideration and the difference between this average and the yield of the trial plat determined. This difference is calculated for each trial plat, and the average for all the control plats in the field is also found. The calculated difference for each trial plat is finally added to or subtracted from the average of the control plats, according to whether the difference was positive or negative. The error of the yields obtained for the different plats is represented by the difference between the calculated yields and the average of the actual yields for all trial and control plats.—F. W. WOLL.

Experiments in electroculture, R. LÖWENHERZ (*Ztschr. Pflanzenkrank., 15 (1905), Nos. 3, pp. 137-151, figs. 3; 4, pp. 205-225*).—The work on electroculture by different investigators is reviewed, and the results obtained by the author are reported.

It is concluded that for the purpose of studying the influence of electricity on the growth of plants it is better to make few, but very accurate experiments, than to make numerous tests with different plants. In tests made by the author it was

found that the position of barley grains with reference to the direction of the electric current had a very marked influence upon the electrical effect.

Electrolysis in these experiments had an injurious effect upon the growth of the plants, and it is concluded that this could not have been due alone to the decomposition products formed in the soil by its action, as otherwise the position of the grains with reference to the direction of the current would not have been so marked. The injurious effect of electricity upon plants when the direction of the current was not reversed at all, or only 2 or 3 times during every 24 hours, was no longer noticed when the current was reversed twice per minute.

The influence of lime nitrogen on the germination of the seeds of agricultural plants, B. SCHULZE (*Fühling's Landw. Ztg., 54 (1905), No. 24, pp. 817-822, dgms. 2*).—Experiments were made with wheat, rye, oats, barley, mustard, sugar beets, buckwheat, flax, carrots, and potatoes. The crops were sown or planted at different intervals after an application of lime nitrogen had been made.

The results showed in general that lime nitrogen may affect injuriously the germination and vitality of seed when a sufficient interval of time is not allowed between its application and the sowing and planting of the crop. This injurious influence seemed more apparent on a light sandy soil than on heavier and more fertile soils. It is recommended that lime nitrogen be applied at least from 8 to 14 days before seeding or planting. By this method all danger of injury may be avoided.

Adulteration of Kentucky blue grass and orchard grass seed, J. WILSON (*U. S. Dept. Agr., Office Sec. Circ. 15, pp. 5*).—Of 251 samples of Kentucky blue grass 41 were found to be adulterated with seed of Canada blue grass, and of 265 samples of orchard grass seed 133 were found to contain common seed adulterants, mainly English rye grass and meadow fescue. The samples were bought in the open market and the orchard grass samples were obtained from 24 States. The percentage of adulterants found in the different samples is given in a table.

The value of fertilizer experiments on meadows, T. REMY (*Fühling's Landw. Ztg., 54 (1905), No. 21, pp. 738-741*).—Cooperative fertilizer experiments on meadows conducted for 2 and 3 years in succession are reported, and the variation in the results is pointed out.

The author concludes from the data that in order to find out with comparative certainty the fertilizer requirements of a meadow the experiment should comprise 5 plats, one of which receives nitrogen, potash, phosphoric acid, and lime, while on each of the other plats 1 of these elements is omitted. It is also recommended that the experiments be carried on for at least 3 years in succession, and it is pointed out that duplicate experiments add greatly to the certainty of the results.

The rate of seeding grass seeds, O. GLAERUM (*Akerväkstforsög i 1904. Christiania, 1905, pp. 74-98*).—Conclusions with reference to seeding the common grasses are based on the results of cooperative experiments carried on for over 10 years.

The maximum amount of seed of Norwegian red clover seemed to be between 25 and 30 kg. per hectare, the best results being secured with 25 kg. The maximum amount of Alsike clover was about 30 kg., with the most profitable amounts ranging from 25 to 27.5 kg. per hectare. The maximum, and likewise the optimum, quantities for timothy, orchard grass, meadow fescue, and awnless brome grass were 30, 55, 90, and 90 kg. of seed per hectare, respectively. From 55 to 60 kg. of seed of perennial rye grass per hectare gave the best results.—F. W. WOLL.

The influence of precipitation and temperature on the yield of hay crops, G. HOLTSMARK (*Norges Landbr. Höiskoles Skr., 1905, No. 7, pp. 16*).—The author bases his deductions on observations made during the past 30 years.

The data indicate that either a high average temperature in May and a heavy precipitation during October, or a low precipitation and low temperature in November of the preceding year, and a heavy precipitation during March, a low precipitation and low temperature in May, and a high average temperature in June of the same

year are the most important factors tending to decrease the yield of hay crops. Among the causes tending to increase the yield are a low average temperature and heavy precipitation in May, a heavy precipitation in September, a high temperature and heavy precipitation in November, and a high average temperature in December of the preceding year, and a heavy precipitation in May and June, and a low average temperature in June of the same year.—F. W. WOLL.

Effect of time of cutting on the yield and composition of hay, S. HALS (*Tidsskr. Norske Landbr., 12 (1905), No. 2, pp. 77-83*).—Plats of a third-year timothy and a first-year clover field were cut on 3 different dates in June and July. The quantities of protein secured in the second cutting, when timothy was beginning to bloom and the clover was in full bloom, were higher than in either of the other cuttings. The same was true with reference to phosphoric acid, potash, and lime, but the differences here were only small as compared with the first cutting.—F. W. WOLL.

The protein content of barley and potash manuring, O. REITMAIR (*Ztschr. Landw. Versuchsw. Oesterr., 8 (1905), No. 11, pp. 983-1014*).—The results of 30 cooperative fertilizer tests with barley are reported and discussed.

In a series of 14 tests made under the direction of the author the crop followed sugar beets on deep, fertile, loam soils. Each individual experiment comprised 2 unfertilized plats in addition to 1 receiving 75 kg. of nitrate of soda and 200 kg. of superphosphate per hectare, and another receiving together with this application 200 kg. of 40 per cent potash salt. The use of nitrate of soda and superphosphate apparently increased the yield per hectare by 216 kg. and the use of potash by 104 kg., but in both cases this increase did not cover the outlay. In 3 of these tests the application of potash seemed to have reduced the protein content, while in the remaining experiments no reduction was apparent.

Similar results were obtained in a second series of 16 tests, supervised by A. Mahner. The author states that in the 30 tests under consideration potash fertilization has not shown the effect of reducing the protein content, but on the contrary, rather a tendency to increase it. It is believed that all other factors of growth, especially total temperatures and moisture, have a greater influence on the quality of the barley than the fertilizer applied.

In over 80 per cent of the tests the addition of potash seemed to have increased the weight of the grain. The results of other experiments indicating that potash fertilization does not reduce the protein content of barley, but does exert a favorable influence on the weight of the grain, are reviewed. In one of these tests the use of phosphoric acid seemed to have reduced the protein content of the barley.

The second part of this report is a refutation of the stand taken by Stoklasa with reference to this problem.

The use of whole and halved fodder beets in seed production, H. BRIEM (*Fühling's Landw. Ztg., 54 (1905), No. 21, pp. 733-738*).—In discussing the subject the author points to an instance in which only 370 out of 2,000 well-formed and heavy selected beets were found rich enough to be used as mother beets.

The sugar content in the entire selection varied from 2 to 13 per cent, and in the beets used for seed the minimum sugar content was 8 per cent. It is held that under such circumstances the maximum production of seed from a single individual is most important, and experiments are reported comparing the yield of seed from individual beets planted whole and when divided into 2 equal parts and planted separately. Forty whole beets of the Mammoth variety produced 6,300 gm. of seed and 40 individuals grown from halves produced 4,900 gm., the relation being as 100 to 155 when the yield of 1 whole beet and 2 halves are taken into consideration.

Corn culture, J. F. DUGGAR (*Alabama Col. Sta. Bul. 134, pp. 169-203, figs. 5, dgm. 1*).—Of 52 varieties of corn tested during the past 10 years Mosby, Cocke, Henry Grady, and Sanders were among the most productive.

The so-called two-eared type of varieties gave larger average yields than the type with the smaller number, but larger-sized ears. Seed of certain varieties from Virginia and Tennessee proved superior to that from Delaware, Illinois, Alabama, and Georgia; but whether this was chiefly due to climate or to more careful selection of the seed corn obtained could not be determined. Early varieties were relatively unproductive, and many of them from northern-grown seed produced a large proportion of unsound corn.

In 6 tests the lower ear used for seed gave a slightly larger yield than the upper ear, but in 2 tests the upper ear gave the better yield. Subsoiling, the depth of the first cultivation, planting in the water furrows, and applying a part of the fertilizer before planting and a part at the second cultivation instead of using it all before planting, did not prove of importance.

Pulling the fodder slightly decreased the yield of grain. The average yields of dry blades was 515 lbs., of cured tops 473 lbs., and of cured stover 1,799 lbs. per acre. Plowing under velvet bean stubble gave an apparent increase of 4.3 bu. per acre, and where the entire growth was used as a fertilizer the first corn crop was increased by 12.3 bu. and the second by 4.4 bu. Where cowpea vines were plowed under 8.9 bu. more per acre was obtained than where only the stubble was used. Plowing under beggar weed which grew after the corn was laid by seemed to have increased the yield per acre by 5.4 bu. Where velvet bean and cowpea vines were plowed under the addition of acid phosphate proved profitable. Nitrate of soda appeared to be a better source of nitrogen than either cotton-seed meal, cotton seed, or barnyard manure.

Iowa's immature corn, C. REINBOTT (*Iowa Agr.*, *6* (*1905*), *No. 1*, *pp. 16–18*).—This article is a synopsis of a thesis on maturity in corn. In the fall of 1904 corn of 3 different grades of maturity was selected on 5 different dates from September 20 to November 7. The samples selected were immature undented corn in the milk, medium mature corn with about one-half of the kernels dented, and mature corn with the kernels dented and glazed. The shrinkage of the samples from the time they were harvested until February 1 is recorded. A very appreciable increase in the amount of dry matter as maturity advanced was observed up to October 13. The immature corn, however, continued to store up matter in the grain for the rest of the period of the experiment.

The effect on the vitality of corn harvested at different stages of maturity was also studied. In thoroughly air-dried husked corn the precentage of strongly germinating kernels increased directly in all cases except one with the maturity. In corn left in the shock until late fall the germination was lowered and varied less regularly than in the husked and dried corn. The immature corn harvested September 20 had shrunken 58 per cent by February 1, and gave 67.7 per cent of strongly germinating kernels. This high germination was due to thorough drying. It is advised to select matured varieties adapted to the locality and to allow the seed corn to remain on the stalk until quite mature, giving it thorough aeration and drying after harvesting.

A study of the effect of dilute solutions of hydrochloric acid upon the radicles of corn seedlings, F. A. LOEW (*Reprinted from Rpt. Mich. Acad. Sci.*, *7* (*1905*), *pp. 50–52*).—The experiments here described show that by growing corn seedlings in dilute solutions of hydrochloric acid the amount of acid is reduced.

The radicles killed in $\frac{1}{256}$ normal hydrochloric acid contained 3.952 per cent of ash, as compared with 7.415 per cent in normal radicles. The ash of the killed radicles contained 2.41 per cent of chlorin and that of the normal 8.96 per cent, while for potash the corresponding figures were 34.17 and 38.76 per cent, respectively. Bacteria and fungi thrived in the solution in which the seedlings were killed, but none were perceptible where seedlings were kept in distilled water for 1 week. The

seedlings killed in $\frac{1}{250}$ normal hydrochloric acid excreted material rich in potassium, and those grown in distilled water also excreted potash or some other alkali.

Since the amount of acid in solutions in which the seedlings were grown was reduced, it is believed that the death was caused by chemical action; and since the killed radicles contained less potassium than the normal ones and the solution in which they were killed was rich in potassium, it is thought that this chemical action takes place between the acid of the solution and the potassium of the radicle. The behavior of bacteria and fungi in the solutions is taken as suggesting that the excretions or extractions caused by the acid solutions might be some organic compound especially nutritious to these organisms.

Cotton growing in Australia, J. BOTTOMLEY (*Melbourne: Mason, Firth, & McCutcheon [1905], pp. 24, figs. 17*).—This is a discussion on cotton growing in Australia, with special reference to a variety originated by crossing a cotton from the upper Amazon region and one from Mexico, both of the Sea Island type. This variety is known as Caravonica, and is described as having a staple very long, strong, and regular and of woolly appearance.

Cooperative potato experiments, 1904, M. WEIBULL ET AL. (*Malmö. Läns K. Hushåll. Sållsk. Kvrtlsskr., 1905, No. 1, pp. 167–206*).—Experiments with 15 varieties of potatoes were conducted on 5 farms.

The highest average yields of tubers for the leading varieties were as follows: Professor Maercker 250, Geheimrat Thiel 247, and Up-to-Date 237 hectoliters per hectare. In starch content Fürst Bismarck led with 22.1 per cent, followed by Professor Wohltmann with 20.6 and Bund der Landwirte with 20.3 per cent. The leading varieties in the production of starch per hectare were Professor Maercker, Geheimrat Thiel, and Silesia, producing 3,570, 3,440, and 3,150 kg., respectively.

Fertilizer tests were carried on with 4 varieties on 20 different farms. Half the number of plats received no manure, while the remaining plats received 250 kg. each of nitrate of soda, 20 per cent superphosphate, and 37 per cent potash salt per hectare, with the exception of certain plats manured in the fall of 1903, which were given 100 kg. less of nitrate of soda and 50 kg. less of superphosphate and potash salt. The results are shown in the following table:

Influence of commercial fertilizers on yield and starch content of potatoes.

Variety.	Without commercial fertilizers.			With commercial fertilizers.		
	Potatoes per hectare.	Starch.		Potatoes per hectare.	Starch.	
			Per hectare.			Per hectare.
	Kilograms.	*Per cent.*	*Kilograms.*	*Kilograms.*	*Per cent.*	*Kilograms.*
Up-to-date	15,760	19.8	3,120	19,960	18.3	3,650
Professor Maercker	15,610	20.5	3,200	19,480	19.5	3,800
Geheimrat Thiel	14,550	20.5	2,980	18,800	19.3	3,630
Silesia	14,370	21.0	3,020	18,740	19.8	3,710

— F. W. WOLL.

Cooperative potato experiments, 1904, H. JUHLIN-DANNFELT and S. RHODIN (*K. Landtbr. Akad. Handl. och Tidskr., 44 (1905), No. 2, pp. 105–154*).—Variety and fertilizer tests were made. Fifteen varieties were grown on 62 farms in different parts of Sweden. The largest average yields were secured from Paulsen Rothauge, Up-to-Date, Leksand, Mossros, Jämtland, and Cimbal President Krüger. Agnelli, Dolkowsky Topas, Leksand, Paulsen Rothauge, Jämtland, and Up-to-Date, in the order given, produced the largest yields of starch.—F. W. WOLL.

The sprouting of seed potatoes, R. B. GREIG (*Aberdeen and No. of Scot. Col. Agr. Bul. 3, pp. 9*).—Experiments with sprouted seed potatoes were conducted on 9

different farms with 7 varieties and the gain in total crop in favor of the sprouted seed ranged from 18¼ cwt. to 3 tons 1¼ cwt. per acre. In the production of marketable tubers there was a still greater gain in favor of the sprouted seed. Of the varieties grown Northern Star and King Edward VII were the most productive. Directions for the construction of boxes for sprouting seed are given and the advantages and disadvantages of the system are pointed out.

Aerial tubers of the potato, P. DE VILMORIN (*Bul. Soc. Bot. France, 52 (1905), No. 4, pp. 535–537, fig. 1*).—The occurrence of aerial tubers in the potato is reported as being more frequent in varieties with colored than with those of white tubers.

The author observed the production of aerial tubers at different times, especially by the varieties Cardinal, Giant Blue, and American Wonder. They are generally found when the plant has a luxuriant growth as a result of soil moisture. They appear late in the growth of the plant and are located on the lower part of the stems in the axils of the leaves, and correspond to secondary branches hypertrophied and enlarged with reserve material. The occurrence of aerial tubers on two branches originating in the inflorescence of a plant of Giant Blue is described.

The improvement of common varieties of rye in lower Austria, G. PAMMER (*Ztschr. Landw. Versuchsw. Oesterr., 8 (1905), No. 11, pp. 1015–1053, pls. 7*).—Cooperative work in the improvement of common varieties of rye by means of selection is described.

The selection of the breeding material was based upon spike characters representing 4 types. The extent to which the characters were transmitted was observed, and an average of about 50 per cent of the progeny showed the characters of the type. A larger yield was secured from plants with crowded spikes of medium length than from plants with longer and more open heads. The dominance of a particular shape of kernel in an ordinary variety determined the specific character of the grain and it was found that this character was correlated with the prevailing type of spike. It is recommended that for breeding purposes this type of spike be selected because it produces the least variation, gives the highest yields, and thus facilitates the origination of strains adapted to a certain locality.

Within the type it is suggested that that form of the kernel showing the highest percentage be regarded as the basis of selection. In subsequent work only those plants which transmitted this form of the kernel are to be used. It is believed that through this method uniformity in the shape and size of the kernel is most quickly secured and in this way the loss in cleaning grain reduced. This method of selection tends to maintain the type together with its yielding capacity and its fixedness.

The progeny of the plant nurseries under field conditions, although only 1 year removed from the selection of the heads, gave higher yields and grain of better quality than ordinary unimproved rye of the same variety. A pedigreed variety produced more grain and also more straw than an improved strain of this selection, but in quality of grain they were about the same.

Saccharine sorghums for forage, C. R. BALL (*U. S. Dept. Agr., Farmers' Bul. 246, pp. 37, figs. 7*).—This bulletin presents a classification of sorghums, notes the introduction of the crop into the United States together with its area and importance, describes the principle varieties, and gives directions for its culture and uses.

The 4 leading varieties in extensive cultivation are Amber, Orange, Sumac or Redtop, and Gooseneck. The general requirements of the crop are very similar to those of corn, but being a stronger feeder, it will do better than corn on thin soils. A sorghum crop leaves the soil in poor mechanical condition, but it has the advantage of being more resistant to drought than corn and of being also more successful on alkali soils. The crop is grown for pasture, soiling, hay, fodder, silage, and seed. It is especially valuable as a pasture for sheep and hogs as well as a summer and autumn feed for dairy stock. When checked in its growth, prussic acid may form in the leaves and the crop then become injurious when fed to stock. It is best cut for hay

or green feeding from the time of heading until the seeds are in the dough stage. Both the seed and the fodder are rich in carbohydrates, and are best fed in connection with materials containing protein.

The culture of the sugar beet, G. W. Shaw (*California Sta. Circ. 13, pp. 21, figs. 3*).—This circular gives detailed information on sugar-beet culture as practiced in the most successful beet-growing sections. The adaptability of varieties, the kind of soils suited to the crop, the preparation of the soil in the fall and spring, irrigation of beets, and their cultivation and harvesting are discussed.

Experiments . . . sugar beet, G. Clarke (*Chelmsford, England: County Tech. Labs., 1906, pp. 22, pl. 1, figs. 3*).—Cooperative culture tests with 5 varieties of sugar beets were carried on in Essex in 1905 in five different localities. An average yield of 18.3 tons per acre, with 16.7 per cent of sugar in the beet and a purity of 84.7, was secured.

Evaporation by the sugar cane plant, Z. Kamerling (*Meded. Proefstat. Suikerriet West-Java, 1905, No. 87, pp. 22*).—Several experiments in which the water evaporated by the cane plant under different conditions was determined are reported.

In one test with well-developed canes the quantity of water evaporated during 24 hours, when the plants were exposed to the direct rays of the sun only during the afternoon, averaged from 183 to 292 gm. per plant. In another instance a plant of about 6 weeks' growth and exposed to the sun during the entire day evaporated 350 gm. in 24 hours. The average results with 9 different plants 5 mos. old show an evaporation of 1¾ liters of water per day. Further data on the evaporation of water by sugar cane are reported, and it is pointed out that the factors most largely influencing this activity of the plant are the distribution of the roots, physical condition of the soil, soil moisture content, leaf surface, temperature, and sunlight conditions. The effect of the curling of the leaf on evaporation is discussed.

Proceedings of the third annual convention of the Interstate Sugar Cane Growers Association (*Proc. Interstate Sugar Cane Growers Assoc., 3 (1905), pp. 110*).—Among a series of papers bearing on the sugar-cane industry several treat of the culture of cane and its cost of production in different southern States.

Notes concerning seed wheat, G. W. Shaw (*California Sta. Circ. 16, pp. 8, figs. 2*).—This circular reviews previously noted results secured at a number of stations with seed wheat grown on different soils, selected from different sized heads, and separated into large, small, heavy, light, plump, and shriveled kernels. Directions for the prevention of smut by the formaldehyde, copper sulphate, and hot water methods are given.

HORTICULTURE.

The farmer's vegetable garden, J. D. Lloyd (*Illinois Sta. Bul. 105, pp. 152–205, pls. 4, figs. 8, dgms. 3*).—This bulletin presents details of the management of a half acre of ground used as a vegetable garden for 5 years beginning in 1900.

The cost of preparing and maintaining the garden each year, vegetables planted, and the quantity harvested, and their value, have been systematically recorded. The half acre was made in the form of a rectangle and the rows planted lengthwise of the garden and far enough apart to permit horse cultivation. The following table shows the value of the products obtained from the garden for each of the 5 years of the experiment, the total expense each year, and the net profits:

Cost and value of a farmer's garden.

	1900.	1901.	1902.	1903.	1904.	Average.
Value of products	$83.84	$68.47	$124.31	$112.73	$136.81	$105.23
Total expense	32.06	35.06	30.96	28.10	27.73	30.78
Net profits	51.78	33.41	93.35	84.63	111.08	74.85

The following are among the more important conclusions of the author relative to vegetable gardens:

"There is little danger of making the soil too rich for a vegetable garden, for although a total of ninety-eight loads of manure were applied to the half acre during the 5 years, none of the vegetables at any time suffered in point of productiveness by reason of too rampant a vegetable growth. The use of hand tools is unnecessary in the preparation of a seed bed if the soil is worked at the proper time. The labor of hand weeding may be reduced to a minimum by planting in freshly worked soil only, tilling close to the rows early in the season, and permitting no weeds to ripen their seed. The use of a wheel hoe saves labor in the care of a garden, even when much of the tillage is to be done with a horse."

Vegetable growing (*Horticulture, 3 (1906), No. 8, pp. 227, 228*).—Abstract of an address by W. W. Rawson before the Massachusetts Horticultural Society, in which he states that he has found the arc electric light beneficial for the growing of lettuce under glass, and that he is securing promising results by the use of a current of electricity in the soil in his lettuce house.

Quality of vegetables and fruits for the home garden, L. and EFFIE M. BARRON and S. W. FLETCHER (*Country Life Amer., 9 (1906), No. 5, pp. 567–574, figs. 45*).—Illustrations and descriptions are given of what the authors term best-flavored varieties of vegetables and fruits. Cultural directions are given for the varieties, followed by a discussion of the principles of cooking that underlie the best methods for their preparation.

Planting tables for flowers and vegetables (*Suburban Life, 2 (1906), No. 3, pp. 126, 127*).—Tables are given showing when to sow seed, set out plants, distance to transplant, height of plants, and season and color of bloom of 52 kinds of flowers, and the time of planting seed either indoors, in hotbeds, or outdoors, time of transplanting, distance apart in rows and between plants, the amount of seed required, and the time of maturity of 52 kinds of vegetables.

Classified planting list for annuals and vegetables, P. T. BARNES (*Gard. Mag. [N. Y.], 3 (1906), No. 3, pp. 139–141, 155, 156*).—Cultural directions are arranged in tabular form for 10 flowering annuals useful as cut flowers, 6 fragrant-flowered annuals, 6 climbing annuals, 6 annuals that resow themselves, 6 annuals for sunny places, and the same number for shady places, rocky places, sandy soils, heavy soils, very cold climates, 6 annuals that bloom after frost, 6 that resist drought, and 5 everlasting-flowered annuals.

In each case the date of flowering is noted, the color of the flowers, and the height to which they grow. The vegetables are classified as pot herbs or greens, salad plants and sweet herbs, seeds and fruits. Type varieties of vegetables to plant in order to secure a succession throughout the season are given.

Fifty dollars per acre from cucumbers, W. C. COLLINS (*1905, pp. 10*).—This brief pamphlet gives practical directions for the culture of cucumbers for pickling purposes.

Breeding sweet corn—cooperative tests, B. D. HALSTED (*New Jersey Stas. Bul. 192, pp. 30, pls. 4, figs. 8*).—The author has experimented extensively in the cross-breeding of sweet corn, and has sent many samples of the hybrid corns to the farmers throughout the State to grow in cooperative tests with the station.

In the production of sweet corn it is necessary that each variety be planted away from other varieties in order to prevent interpollination. The results of this breeding work has shown that the breaking up in the second and subsequent generations of seed clearly follows the law of Mendel. The bulletin explains this law in considerable detail, and thus indicates to those who are carrying on the cooperative tests the character of the corn they may expect in different generations by planting the different kinds of seeds found on the same ear of hybrid corn.

In crossing Black Mexican on different varieties of sweet corn, black has been found a dominant color. The flinty nature of the grain of "Earliest Table" when crossed on Early Sunrise was a dominant character. Relative to the field-mixing of corn the author states that "should a trucker plant field corn with his sweet every germ cell of the latter fertilized by the field sort would develop into a starchy kernel, but the size of the ears, number of rows and length and breadth of grain are largely determined by the mother plant."

Some experiments were also made in planting kernels from a solid red ear between two rows of white corn. In the resulting crop there was not a single instance of red grains being mixed with white grains, nor were white grains found on any of the red ears produced. Similar results were obtained when the "Striped Evergreen" variety of sweet corn, which has grains more or less splashed with red, was planted under similar conditions. A number of unexpected results obtained in crossing sweet corns are mentioned.

Results of experiments with mushrooms, F. CANNING (*Amer. Florist, 26 (1906), No. 933, p. 610, fig. 1*).—The author grew 5 varieties of American mushrooms in comparison with varieties grown from English and French spawn. The details as to date of spawning, first and last picking, total weight of crop, etc., are shown in tabular form.

The mushrooms were all grown in a bed under the greenhouse benches, an area of 9 sq. ft. bed surface being given to each of the American varieties and 18 sq. ft. to each of the English and French varieties. The heaviest yield was obtained from the American variety Arvensis, 13.9 lbs., followed by Alaska, Columbia, Bohemia, and Dr. Galloway in the order named, the latter yielding but 3.5 lbs. The yield of English spawn was 4.75 lbs. on double the area employed with the American varieties, while the yield from the French spawn was but 0.5 lb. Both the English and French spawn is believed to have been 2 years old instead of fresh spawn.

Canning fruit and vegetables. Preserving fruit juices, E. F. PERNOT (*Oregon Sta. Bul. 87, pp. 14*).—An account is given of experiments extending over 2 years, in the canning of vegetables and fruits, and the preservation of fruit juices for domestic purposes.

In commercial practice canned goods are usually processed to a temperature of 230 to 250° F. for 20 to 30 minutes, as a result of which the tissues of the vegetables or fruits are more or less destroyed and the material becomes mushy, especially after shipping long distances. In the author's work, fresh, clean fruits and vegetables were put in clean cans and covered over with water that had been boiled to sterilize it. The cans were then sealed, after which they were heated to a temperature of 165° F. for 15 minutes. After being allowed to stand 24 to 48 hours, they were again heated as previously and the operation repeated the third time, which completed the process.

Thus treated tomatoes, green beans, wax beans, cauliflower, asparagus, and cherries kept perfectly, and ranked as the highest grade of canned goods. Their natural color, flavor, and texture were retained, and the beans when taken from the can could be broken in the same manner as when fresh. Beans preserved in glass jars were not so satisfactory, as considerable difficulty was experienced in keeping them tightly sealed during the second and third heating. The peas and corn treated in this same manner were a failure, even when processed at a temperature of 212° F. for 20 minutes on 3 successive days, but when processed at a temperature of 240° F. for 30 minutes, kept well, but the product was inferior.

The principle involved in this method of canning fruits and vegetables is that the vegetative cells of the micro-organisms which produce fermentation in canned goods are killed at a temperature of about 160° F. The spores, however, are not killed at this temperature. By waiting a day or so after the first heating many of these spores

germinate. The second heating is for the purpose of killing all the spores that have thus germinated. Should any spores still remain, they will be killed at the third heating. It is absolutely essential that all micro-organisms be killed in order to prevent the spoiling of the canned goods. It is recommended that in canning fruits containing pits the pits be first removed, as there is danger of the pits germinating if kept in a warm temperature. An investigation was made of the organisms which cause the spoiling of corn and peas. In the swelled cans of both these products the same organism was found. It is described as an obligate anaerobe, which readily forms long oval spores situated near the end of single rods, and in microscopical appearance and cultural characteristics is identical with *Bacillus spinosus*.

Experiments were made to determine the thermal death point of this organism and its spores, pure cultures being submitted to different temperatures for different lengths of time, beginning with 160° F. Even after heating to 200° F. for 30 minutes, the material made a strong bacterial growth. Some notes are given on the action of enzyms in canned goods and the micro-organisms which produce poisonous ptomaines. Relative to the reheating of canned goods which have swelled as a result of fermentation, the author states that this material is dangerous and should be thrown away.

In the preparation of sweet cider sterilized beer bottles were filled to the neck with the fresh material and then put into a chest into which steam was turned and the temperature of the material raised to 160° F. for 10 minutes. The bottles were then corked with sterilized corks and tied in, and after 24 hours the bottles were again heated to the same temperature and the operation repeated the next day for the third time. Thus treated the material maintained its flavor without any cooked taste and remained sweet indefinitely. It is stated that the same method may be used in preparing other kinds of fruit juices.

Small canneries in Virginia, R. H. PRICE (*Rpt. Va. Farmers' Inst., 2 (1905), pp. 115–120*).—Estimates as to cost of machinery and supplies for the canning industry, with data as to the number of cans obtained from a bushel of various fruits and vegetables.

Report of fruit experiment stations of Ontario, 1905, L. WOOLVERTON ET AL. (*Ann. Rpt. Fruit Expt. Stas. Ontario, 12 (1905), pp. 80*).—A general report is given by the secretary showing the fruits distributed for testing to all the different fruit stations with an account of visits to various stations, and of the more prominent lines of work outlined for 1906. The report of the instructor of the fruit experiment stations, Prof. H. L. Hutt, is included, together with the papers read at a meeting of the Fruit Growers' Association, and a detailed report of the experimenters at the different stations relative to the different varieties of orchard and small fruits under test.

Fruits recommended for planting in Ontario (*Ontario Dept. Agr. Bul. 147, pp. 11*).—Lists are given of the varieties of orchard and small fruits which succeed best in each of the different districts of Ontario.

Fruit cultivation in Ceylon, H. F. MACMILLAN (*Trop. Agr. and Mag. Ceylon Agr. Soc., 25 (1905), No. 8, pp. 486–497, pls. 2*).—A general discussion of this subject with specific reference to many of the edible and inedible fruits grown in Ceylon, and illustrations of 51 edible and 69 inedible fruits.

Experiments in orchard culture, W. M. MUNSON (*Maine Sta. Bul. 122, pp. 181–204, pl. 1, dgms. 4*).—A further report is given on the orchard fertilizer experiments reported by the author for the year 1902 (E. S. R., 15, p. 39).

Considerable weakness has been developed in the seedling stocks used, which illustrates the advantage of using some well-known hardy vigorous sort as the foundation of the orchard, rather than miscellaneous seedlings. The main purpose of the experiments is to determine the relative value of cultivation and mulching for orchards with or without fertilizers. Generally speaking, the cultivated trees have made a larger growth than the uncultivated, and those fertilized more than

the unfertilized. Gravenstein mulched and fertilized made slightly larger growth than when cultivated and fertilized.

The average yields have been slightly in favor of cultivation. This was particularly striking in 1905, when an average of 4 bu. per tree was obtained on the cultivated area as compared with 2.8 bu. per tree where mulching was used. The yield on the portions fertilized with stable manure has been slightly heavier than where commercial fertilizers have been applied. In experiments to determine the specific effect of different potash salts on the apple, no noticeable difference has yet developed in the character of fruit or the behavior of trees as a result of the form of potash used.

In 1902, 100 trees in a neglected orchard were set aside for the purpose of determining the best methods of renovation. Pruning, cultivating, and fertilizing have been practiced, and the results on all the plats are very satisfactory. The best results have been obtained where a complete fertilizer was used. On trees which received an excess of nitrogen there was a noticeable lack of color in the fruit, and in 1904 a considerable injury occurred to both fruit and trees as a result of either a too free use of nitrogen or of the absence of potash. Both fruit and foliage dropped and much of the fruit was cracked, while the remainder was as soft and mellow in October as it should have been the following May. Good yields of fruit have been obtained and the author believes that the experiment demonstrates that the off year in the case of Baldwins is an unnecessary condition which ought not to exist in a well-managed orchard.

A specific test is being made of the relative values of the Fisher fertilizer formula for fruits and the station formula. The Fisher formula calls for a mixture of 350 lbs. nitrate of soda, 120 lbs. sulphate of ammonia, 230 lbs. sulphate of potash, 200 lbs. acid phosphate, and 50 lbs. kieserite. These are thoroughly mixed and sown on the surface of the ground under the tree a little farther out than the limbs extend, at the rate of 10 lbs. to a medium sized tree, from May 1 to 10, or as soon as the blossom buds begin to open. The station formula contains about 5 per cent less nitrogen, 2 per cent more phosphoric acid, and 4 per cent less potash and costs about $5 less per ton. Good results have thus far been secured with both formulas but no conclusions have been drawn as yet.

In the top-working of orchards a specific test is being made of the relative value of scions from bearing trees of known value, as compared with scions from nursery trees or miscellaneous sources. This work has been underway two years. Some experiments have also been made to determine the effects of cultivation on the keeping quality of fruit as compared with sod-grown fruit. The results obtained thus far are contradictory.

In the cover-crop work at the station, winter rye has proved most satisfactory on strong land. Where the soil is in need of nitrogen winter vetch (*Vicia villosa*) or spring vetch (*V. sativa*), has proved most satisfactory.

In order to emphasize the importance of rational orchard treatment in other sections of the State, some cooperative experiments have been planned with growers in the vicinity of New Gloucester. This work is briefly outlined. The bulletin contains numerous diagrams showing the arrangement of the various experimental orchards, and tables giving in detail the data secured as to the annual growths of trees on mulched and cultivated areas, and the yields obtained, etc.

Suggestions upon the care of apple orchards, E. WALKER (*Arkansas Sta. Bul. 91, pp. 141-210, figs. 18*).—Suggestions based on the results of experimental work are given for the care and management of apple orchards, including pruning, spraying, fertilizing, cultivation, cover crops, resetting gaps in old orchards, etc.

In rejuvenating an orchard of 27 acres of old bearing trees, good cultivation, pruning, spraying, and the use of both stable manure and commercial fertilizers was given. The work was begun in 1904, and in 1905 534 bbls. of No. 1 apples were

secured, having a value of $2,077.57, and $240 worth of No. 2 culls and vinegar apples total value, $2,317.50, while the expense of production was $883.30. An uncultivated orchard of 30 acres in the same locality yielded, in comparison, but 70 bbls. of poor No. 2 apples. The results of analyses of the soil and subsoil in the orchard rejuvenated are given. They show considerably less than half of the humus normally present in average southern soils. In newer ground the humus was greatest in the surface soil, but in the older land it was greatest in the subsoil.

Attention is called to the injury to apples by the green narrow-winged katydid (*Scudderia texensis*). This insect injured from 3 to 5 per cent of the fruit on many trees. The injury consisted principally in the disfiguring of the fruit. The proportion of sound apples on the area first sprayed in going into the orchard was 93½ per cent; in other parts of the orchard the percentage was 84 to 89 per cent, thus showing that the best work in spraying was done when the men were fresh. The cost of spraying was 3¾ cts. per tree.

Some of the trees were dust sprayed, but the foliage and fruit of these trees were not so perfect as with the liquid. It gave better results against codling moth than against scab, and was very efficient for tent caterpillars. The notion commonly prevalent among orchardists in Arkansas that pruning must not be practiced was found to be erroneous when conducted in a careful and intelligent manner.

The use of nitrate of soda at the rate of 3 lbs. per tree greatly promoted the general vigor of the tree, increased the average size of the apples one-third over trees receiving a general fertilizer, and gave much better results than when only 1 lb. of the same fertilizer alone or with 3 lbs. muriate or sulphate of potash or with 20 lbs. slaked lime was used. "The fruit was not so well colored as that of other trees, and was later maturing. On this clayey cherty soil, very deficient in humus, no marked effects followed the use of the other fertilizers mentioned above, when used separately. Lime seemed to help the foliage and color of the apples on trees treated, while the muriate of potash gave a very bright winesap red to the normally brownish Arkansas, or M. B. Twigs." The resets in the orchard were found to make a good growth when care was given them and sufficient fertilizer to insure plenty of plant food within reach of the roots.

Carbon bisulphid was found an efficient remedy for killing sassafras sprouts when used at the rate of a teaspoonful to a tablespoonful on sprouts 3 to 5 feet tall. It was poured down the stems, beginning 6 inches above the ground. It appeared to kill the roots in all instances. Protection from rabbits was secured by painting the trees with white lead mixed with pure linseed oil.

The most serious harvest injuries to apples were found to come from bruises originating in careless handling by the fruit pickers and in the crushing of the riper specimens by the harder specimens in heading in the barrels. By shaking down the barrels every time a half bushel is put in, and filling only slightly above the chine, this source of injury and loss can be avoided.

The Spencer seedless apple (*Amer. Agr., 77 (1906), No. 7, pp. 206, 207, figs. 3*).—An account of a visit to the seedless apple orchard at Grand Junction, Colo., by W. F. Crowley.

The writer states that this orchard contains about 50 trees from 6 to 12 or 14 years old; that the apples produced are not entirely without seeds at all times; that the apple is a good keeper, and that it will compare favorably in size with the Jonathan and is larger than the Missouri Pippin. In flavor and quality it is placed ahead of Ben Davis and on an equality with many other winter varieties. The claim that the variety is seedless is believed to be well founded. There appears to be a semblance of a core, although not nearly as much as in the ordinary varieties. The apple is hollow in the calyx and it is no longer claimed for it that it is wormless. Under like conditions of storage the apples kept as well as Baldwins.

Experience with plums, H. T. THOMPSON (*Trans. Ill. Hort. Soc., n. ser., 39 (1905), pp. 419-428*).—The author, located in Illinois, finds that Japanese and European plums when grafted on native trees are hardier and better suited to the climate. A table is given showing the time of bloom, size, time of ripening, character of the fruit as to cling or freestone, eating and cooking quality, tendency to rot, etc., for 79 varieties.

Orange culture (*New York: German Kali Works, pp. 68, figs. 14*).—Popular directions for the culture of oranges, including fertilizers, irrigation, protection from frosts, etc. Much of the data contained have been drawn from experiment station sources.

Orange hybrids (*Rural New Yorker, 65 (1906), No. 2925, p. 132, fig. 1*).—Further notes are given on the hybrid between *Citrus trifoliata* and *C. nobilis*, which is characterized by having 5 leaflets. (See E. S. R., 14, p. 442.)

Studies on the banana, L. B. MENDEL and E. M. BAILEY (*Science, n. ser., 23 (1906), No. 583, pp. 333, 334*).—Notes on investigations relative to the influence of various abnormal atmospheres and inert surface coatings on the ripening of bananas.

The normal ripening of the banana is essentially an almost complete conversion of starch into soluble carbohydrate, accompanied by a decrease in the total carbohydrate. When bananas were placed in atmospheres of hydrogen, carbon dioxid, or illuminating gas they failed to produce notable amounts of soluble carbohydrate or to show any considerable decrease in total carbohydrate. Practically the same results were obtained when the surface was coated with such material as paraffin. In an atmosphere of oxygen ripening processes were somewhat accelerated.

"Autolyses with the green pulp, or with the green pulp and scrapings of the inner surfaces of the peel, or of the partially ripened pulp, carried out with toluene water under varied conditions, have yielded negative results. The investigation is being extended in various directions."

The Indian jujube (*Trop. Agr. and Mag. Ceylon Agr. Soc., 25 (1905), No. 3, pp. 484, 485*).—An account of the uses of the various species of Zizyphus, including Indian jujube (*Z. jujuba*), also known as the wild "ber," and the common Indian jujube (*Z. vulgaris*), the dried fruit of which is an article of commerce.

The fruit of the jujube is used in the preparation of sirups, confections, and lozenges. Its analysis is reported upon by Prof. W. R. Dunstan, of the Imperial Institute. The pulp of the fruit is composed chiefly of sugar with a small part of pectin and extract matters. Specimens of the fruit were submitted to dealers in cattle food with the hope that it might be used in much the same manner as the carob bean, but as it is more bulky and less nutritious than the latter it is not believed that it will become of commercial importance along this line.

The experiment in cocoa curing on the Gold Coast (*Trop. Life, 2 (1906), No. 2, pp. 22, 23*).—This is a brief review of a report by W. H. Johnson, director of the botanical and agricultural department of the Gold Coast, for 1904, in which the results obtained with washed and unwashed cocoa and of varying periods of fermentation are given.

With 12 days' fermentation there was a loss of 27.21 per cent in weight, while with 4 days' fermentation there was a loss of but 11.42 per cent. When a lot of cocoa was sent to Hamburg that which was fermented only 3 days was valued only 1 to 2 per cent lower than that which had been fermented for 6 days, while the former had lost approximately 10 per cent in weight during the process of fermentation and the latter 17 per cent. It would appear from the returns of the brokers that it is advisable to send cocoa to market unwashed, and that a 4 days' sweating is likely to prove the most remunerative.

Annual report of the horticultural and viticultural expert, A. DESPEISSIS (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 6, pp. 531-545*).—An account of the work

for the year, including lists of the varieties of fruit trees most commonly planted for commercial purposes, data on cost of preparing and shipping fruit from Australia to London, the introduction of new varieties of fruits, including oranges, Smyrna figs, date palms, etc., and data showing the yields of various kinds of fruits in different provinces of western Australia in 1904–5 and of the quantities of orchard products imported in 1904. Notes are given on the prevalent insects of the season and on fruit-eating birds.

The cost of fruit packages, packing material, labor in sorting, wrapping, packing, branding, cartage, wharfage, etc., is placed at 83 cts., while the freight to London is 79 cts. The minimum cost of growing a case of apples is placed at 75 cts. Thus, in order to lay a case of fruit down in London and cover expenses the minimum returns must be $2.37.

The influence of the graft on the quality of grapes and wine, and its employment in the systematic amelioration of sexual hybrids, CURTEL and A. JURIE (*Compt. Rend. Acad. Sci.* [*Paris*], *142* (*1906*), *No. 8, pp. 461–463*).—Careful examination was made of the fruits, seeds, etc., of a variety of grapes on its own roots and when grafted on Rupestris. Analyses of the wine obtained from the fruit of the two vines are also given.

The general conclusions are drawn that a graft may modify both fruit and wine. There is an inverse influence between the stock and scion. The action of the graft is not limited to the duration of its association with the stock, but persists in the buds and scions taken from it. This method of asexual hybridization may be used in systematic amelioration of the grape and its hybrids, and especially the wines obtained from them.

The Lincepina grape, M. B. WHITE (*Horticulture, 3* (*1906*), *No. 9, p. 251, fig. 1*).—This new grape, originated by the author, is stated to be a combination of *Vitis labrusca*, *V. vulpina*, *V. lincecumii*, and *V. vinifera*. The mother parent contained the blood of the Delaware, Lindley, and Brilliant. Clinton was the father parent. The grape is of rather dark-red color covered with lilac bloom. "Its clusters and berries are large, and its quality is pure and sprightly, pulp tender to the center, and so transparent that when held up to the light the seeds are plainly seen."

The production of oil of wintergreen, H. D. FOSTER (*Forestry and Irrig., 11* (*1905*), *No. 12, pp. 565–569, figs. 3*).—A description of the process of distilling wintergreen oil from sweet birch (*Betula lenta*). The bark from an average birch 12 in. in diameter is stated to yield 1 lb. of crude oil, worth about $2.25.

Pruning, training, and trimming trees and shrubs, D. G. MCIVER (*London: Dawbarn & Ward, Ltd., pp. 63, figs. 22*).—Popular directions for the pruning of fruit trees and ornamental shrubs.

The book of the winter garden, D. S. FISH (*London and New York: John Lane Co., 1906, pp. XII + 107, pls. 10*).—The author considers the chief winter-berried trees and shrubs from the standpoint of their ornamental usefulness in the winter.

Directions are given for planting and caring for such trees and shrubs and for the care of herbaceous and other winter-flowering plants in the open. Selections for cold and Alpine plant houses are also given. The final chapter deals with the forcing of plants, such as bulbs, shrubs, and roses. Brief descriptions are given of all the various plants mentioned in the work. This is Vol. 26 of the Handbooks of Practical Gardening, edited by H. Roberts.

The lawn, L. C. CORBETT (*U. S. Dept. Agr., Farmers' Bul. 248, pp. 20, figs. 5*).—Popular directions are given for preparing the soil, seeding, and care of the lawn, with a discussion of its relation to walks, drives, trees, and shrubs.

A study of the bibliography and horticultural literature of the past, G. GIBAULT (*Jour. Soc. Nat. Hort. France, 4. ser., 6* (*1905*), *Nov., pp. 710–743, figs. 3*).—A running account is given of all of the more important horticultural works that have

appeared in French literature or that have been translated into the French language from other sources.

The more important antique works are noted, as well as the illustrated works on plants of the sixteenth, seventeenth, and eighteenth centuries. Works dealing with rural architecture, general treatises on gardening, works on fruit culture, floriculture, vegetable garden, and landscape gardening are also noted, as well as old horticultural and botanical catalogues and books of poems, and journals dealing with horticultural subjects.

FORESTRY.

The tree book, JULIA E. ROGERS (*New York: Doubleday Page & Co., 1905, pp. XX + 589, pls. 176*).—This is a popular manual of the trees of North America, and in addition to the indigenous trees, the author has included many of the more important shrubs and also the more extensively introduced species of both groups.

Artificial keys are given which are based upon easily distinguishable characters, by means of which any species of tree or shrub can be identified and its principal characteristics learned. In addition to the usual descriptions, information is given on the growth, habitat, distribution, uses, cultural adaptations, etc. After giving popular suggestions by which the novice may learn to know trees, the author describes the different species enumerated, grouping them according to families.

In the concluding parts of the work notes are given on forestry, the uses of wood, and the life activity of trees. Under the chapters on forestry, the author describes the care of trees, methods of transplanting, pruning, enemies, etc., and the suggestions offered will be found of practical value not only in forestry, but to the amateur planter or owner of a few specimens, as well as to those having charge of parks and street or avenue plantings.

The illustrations, which are an important feature of the work, are mostly excellent reproductions of photographs showing the various aspects of the tree, its leaves, flowers, fruit, etc.

The forest service: What it is and how it deals with forest problems, G. PINCHOT (*U. S. Dept. Agr., Forest Serv. Circ. 36, pp. 24*).—An account of the organization of the United States Forest Service. The service is organized under 7 offices, each of which has several sections. All of the offices and sections are responsible to the forester.

The sections directly responsible to the forester are those denominated inspection, reserve boundaries, publications and education, silvics, forest law, and forest reserves. The other main offices are Forest Measurements, Forest Management, Forest Extension, Dendrology, Forest Products, and Records. The duties performed by each of these offices are briefly outlined. The circular concludes with a classified list of publications issued by the Forest Service.

Previous to July, 1905, the Forest Service was known as the Bureau of Forestry, and earlier still as the Division of Forestry. The Forest Service deals with the practical uses of forests and forest trees in the United States, and first of all with the commercial management of forest tracts, woodlots, and forest plantations. The care and perpetuation of the national forests are under its control, and it offers cooperation and assistance in the solution of practical forest problems confronting either States or individuals.

A working plan for forest lands in central Alabama, F. W. REED (*U. S. Dept. Agr., Forest Serv. Bul. 68, pp. 71, pls. 4, maps 2*).—The working plan presented in this bulletin relates to two tracts of long-leaf pine land in Alabama, one located in Coosa County and the other in the western end of Bibb County and portions of the adjacent counties of Tuscaloosa, Hale, and Perry.

The lumber company for which the plan was made desire to so manage their lands that the area now being cut over will be able to produce at least 3,000 feet to the acre

within twenty-five years, providing it can be done at a profit. The survey work done as a basis for the working plan consisted principally in the running of valuation surveys, making stem analysis, a study of the logging methods now in use on the tract and their effects on the future productivity of the forest, a study of the losses caused by forest fires and means for preventing them, and a special study at the sawmill to determine the value of lumber sawed from trees of different sizes.

The details secured in these surveys and studies are presented in extended form, and include volume and stand tables.

Forestry in Nova Scotia, K. W. WOODWARD (*Forestry Quart., 4 (1906), No. 1, pp. 10-13*).—Forestry conditions in Nova Scotia and the prevailing timber species are noted, as well as the common methods of lumbering. The country is little suited to agriculture, except in the river basins, but is admirably adapted for forestry purposes. White spruce and fir reproduce abundantly and promise to be the main forest trees of the future in that province.

The principal timbers cut up to the present time have been white pine, red pine, red and white oak, spruce, fir, and yellow birch. Hemlock is just beginning to be cut on a large scale. Maple, birch, ash, poplar, paper and gray birch have not as yet been cut commercially. Up to this time no trees less than 12 in. in diameter have been taken commercially. In summarizing, the author states that Nova Scotia demonstrates the practical application of the selection system as regards spruce forests. Profitable cuttings are made annually, yet the productive capacity of the forest is not impaired.

Forestry and forest products of Japan (*Tokyo: Dept. Agr. and Com., 1904, pp. 118*).—This publication is a part of the Japanese exhibit at the St. Louis Exposition. It treats of forests and forest administration in Japan, noting the forest zones and their principal products, yield of forest products, and gives descriptions of the exhibit presented. Fifty-nine per cent of the total area of Japan, or 577,170,000 acres, is occupied by forests. About 21 per cent of the forests of Japan are conifer, 25 per cent broadleaf trees, and 45 per cent conifer and broadleaf trees mixed.

Weight and shrinkage of Japanese woods, K. MOROTO (*Centbl. Gesam. Forstw., 31 (1905), No. 12, pp. 499-502*).—A discussion of the air-dried weight, specific gravity, and shrinkage of Japanese woods, with an account of the uses to which a large number of species are put in the manufacture of furniture, lumber, etc.

The beginning of lumbering as an industry in the new world, and first efforts at forest protection, J. E. HOBBS (*Forestry Quart., 4 (1906), No. 1, pp. 14-23*).—A historical paper on this subject.

The rise in lumber prices, R. S. KELLOGG (*Forestry and Irrig., 12 (1906), No. 2, pp. 68-70*).—The author estimates that the country now uses about 50,000,000,000 ft. of lumber annually, in addition to which the pulp mills take about 2,000,000 cords of wood, the tanneries 1,500,000 cords of hemlock and oak bark, and the railroads about 115,000,000 ties for renewals alone, besides posts, poles, and firewood. For the latter purpose 146,000,000 cords were used in 1880, and it is probable that as much is used at the present time.

The estimated forest area of the United States is placed at 500,000,000 acres, of which four-fifths is in private hands. The well-managed forests of Germany grow on an average about 50 cu. ft. of wood per acre annually, and were our forests equally well managed the supply of wood would just about equal the demand. As a matter of fact, however, the annual growth of our forests is probably not more than one-fifth that of the German forests.

The use of wood pulp for paper making, S. C. PHILIPPS (*Jour. Soc. Arts, 53 (1905), No. 2739, pp. 700-719*).—An article dealing comprehensively with the various phases observed in the preparation of wood pulp for paper making, including a discussion of the various processes of disintegrating the wood, chemical pulp, and the various uses to which wood pulp is put. Statistics are given upon the pulp imported

into Great Britain during April, 1905, and its value; also the imports for the years 1901–1903. The article has also been published as a separate (Calcutta, Superintendent Government Printing, 1905, pp. 34).

A new saving in the turpentine industry (*Forestry and Irrig., 12 (1906), No. 2, pp. 99, 100*).—Further economy has been effected by the Forest Service in the turpentine industry as the result of experiments carried out during the past season, which indicate that at least an equal flow of resin can be secured from shallower and shorter "faces." It is believed that with this diminution in the severity of the facing operation the ordinary term of 3 or 4 years during which a forest is now worked can be greatly increased.

Report of the committee of 1905 to consider the laws relative to the taxation of forest lands (*Mass. Forester's Off. Bul. 3, pp. 28*).—A synopsis of the laws of the various States and countries on this subject.

Efficient fire protection, A. B. Recknagel (*Forestry Quart., 4 (1906), No. 1, pp. 1–4, figs. 2*).—Details are given of the organization and methods followed in the policing of a tract of 14,000 acres of hard wood in northeastern Pennsylvania at a cost of about $1,710 annually. Each patrolman is provided with an axe, pail, hoe, and shovel. Engines operating on the track are fitted with double spark arrestors in summer. On a convenient siding a tank car of 4,970 gal. capacity has been rigged with hose and double pump as a fire engine.

Results of a Rocky Mountain forest fire studied fifty years after its occurrence, W. J. Gardner (*Proc. Soc. Amer. Foresters, 1 (1905), No. 2, pp. 102–109*).—A report on an examination of the condition of the forests on the southern portion of the Pikes Peak Reserve to determine to what extent the denuded slopes of this watershed are naturally reforested.

The region comprises nearly 79 square miles of extremely rugged mountain land. More than 56 per cent of the district is above 9,000 ft. Three and one-half square miles lie above the timber line. The prevailing forest types are Engelmann spruce, limber pine, red fir, and bull pine. Early in the investigation evidence was obtained to show that a portion of the region had been severely burned about 50 years previously. The reproduction of the forests since that time has been slow and irregular. In some places the new growth is exceedingly dense and in others the ground is still perfectly bare.

Relative to the aspen as a nurse-tree, it was observed that Engelmann spruce, red fir, and other species came in after the fire quite regardless of aspen, though it is stated that wherever the aspen does occur it undoubtedly acts as a valuable soil protector. Where the new growth occurs, Engelmann spruce is most abundant; three-fourths of the young trees of this species was found to be 30 to 50 years old, but comparatively little young growth has started within the past 30 years. The spruces grow extremely slow, trees 2 to 4 ft. tall and 40 to 45 years old being quite common. On an average it is estimated that it takes an Engelmann spruce 25 to 35 years to reach a height of 5 ft. in that region. Most of the diameters are below 2 in. It is stated that the tolerance of Engelmann spruce is remarkable, as trees in old crowded pole forests sometimes persist for 200 to 250 years without attaining a height exceeding 10 to 15 ft.

Investigations on the influence of forests on the ground water table, A. Bühler (*Forstw. Centbl., n. ser., 28 (1906), No. 2, pp. 112–119*).—This is a rather extended review of a 17 quarto page pamphlet written by Dr. Ebermayer and O. Hartmann, and published by Piloty & Löhle, München, 1904, in which an account of 3 years' investigations on the influences affecting the height of the water table were studied. The more important conclusions are stated as follows:

The storing of the ground water is dependent first of all upon the seasonal distribution of the rainfall. Other important factors are the size of the storage basin, the degree of dryness of the soil, the thickness, permeability, and inclination of the

water-bearing strata, and finally the use of water by growing plants. Because of the smaller amount of evaporation and the greater absorption of the soil, the storage of ground water is considerably greater in the winter than in the summer. The influence of forests on ground water can not be measured where the water-bearing strata is inclined, thus giving rise to stream flow.

In the climatic zone of Bavaria, where these experiments were carried on, forests had no effect either on raising or lowering the ground water. It is desired that this conclusion be considered local and as applying to more or less permeable soils. A brief review of other similar work is included.

Rubber, gutta-percha, and balata, F. Clouth (*London: Maclaren & Sons; New York: D. Van Nostrand Co., 1903, pp. XII+242, figs. 30, maps 2, dgm. 1*).—This is the English translation of this work, which first appeared in German in 1899. It contains chapters on the natural history, production, and commercial points of rubber, gutta-percha, and balata, and on their chemical and physical properties. In the case of rubber, there are chapters also on the production of soft rubber goods, vulcanization, hard rubber, and regenerated and artificial rubber. The production and employment of gutta-percha goods is also considered, as well as the principal products made of India rubber, gutta-percha, and balata.

Rubber tapping on Kepitigalla estate, I. Etherington (*India Rubber World, 33 (1906), No. 4, pp. 107–112, figs. 7*).—This estate is considered a typical example of a well-worked plantation of cacao and *Hevea brasiliensis*. The methods of tapping in vogue are explained, and descriptions given of the coagulating factory and machines for coagulating the latex. The spiral method of tapping is described in detail and illustrated.

By this method of tapping the average yield per tree for the preceding year was little over five pounds of rubber. There is very little scrap with this system, and the rubber turned out is of very high grade. It is believed that this system will be widely taken up on plantations, as it is considered one of the most important forward steps made in the industry for considerable time.

A new tapping method for Kickxia elastica, Strunk (*Tropenpflanzer, 10 (1906), No. 3, pp. 141–149, figs. 6*).—In place of the herring-bone method of tapping, the author uses simply perpendicular slits placed about 10 cm. apart.

The yield of rubber obtained is claimed to be fully as great and the trees are much less injured. The yield of rubber is increased if the slits are made at intervals of about 4 weeks. The old slits are not reopened until after several years, when they are completely healed. It is believed that by this method of tapping the work can be much more rapidly performed and the profits considerably increased. Illustrations are given showing the methods of tapping followed and the tools used for making the cuts.

Report on the experimental tapping of Para rubber trees in the botanic gardens, Singapore, for the year 1904, H. N. Ridley and R. Derry (*Agr. Bul. Straits and Fed. Malay States, 4 (1905), No. 11, pp. 424–443, pls. 2*).—Experiments have been carried on with 84 groups including 880 Para rubber trees during the past year. These trees produced a total of 884.5 lbs. of dry rubber.

Various methods of tapping have been investigated. The single incision method is quickly performed, but gives only about one-half the product obtained by the herring-bone method. Trees tapped with the single incision do not recover well and the bark is made difficult for any other method of tapping. It is noted that trees tapped late or early in the year are the slowest to recover. Para rubber trees apparently make their most rapid growth between the sixth and fifteenth years of life, making an annual increment of growth in the trees under observation of 3 to 6 in.

Closely planted trees do not make satisfactory increment of growth, and the yield of rubber increases with the size of the tree from under 0.25 oz. of dry rubber to the inch of girth for small trees to over 0.5 oz. for large ones. This point is further

brought out in some data in which it is shown that 40 tapped trees, averaging 2 ft. 3 in. in girth per tree, produced 18.4 lbs. of rubber, while 20 trees averaging 4 ft. 2 in. in girth yielded 25.4 lbs. of rubber. In another instance 50 trees averaging 1.75 ft. in girth yielded 18.5 lbs. of rubber, while only 15 trees, 5.6 ft. in girth, yielded 33.5 lbs. of rubber.

Extensive tables are given showing the yield of rubber from morning and evening tappings and by different methods of tapping, and growth of different trees under observation. Morning tappings have produced more rubber than evening tappings.

Note on the germination of teak and other seed, R. S. Pearson (*Indian Forester, 31 (1905), No. 11, pp. 635-638*).—The germination of teak seed was seriously injured by abnormally heavy falls of rain. Dhawra seed (*Anogeissus latifolia*), which the author heretofore has been unable to make germinate, was successfully germinated by sowing the seed on well irrigated raised beds, the soil being mixed with a large quantity of coarse sand, the seed sown in June and daily watered by hand. The germination was greatly facilitated by covering the bed with a thick layer of leaves and branches about 18 in. above the ground.

The teak timber trade of Burma, T. A. Hauxwell (*Indian Forester, 31 (1905), No. 11, pp. 618-635*).—The teak timber trade of Burma is shown to be steadily decreasing, while that of Siam is gradually increasing. The causes of this decrease are discussed, chief of which are the diminution in the supply of old girdled timber of large size in Burma, less accessible areas, the increase in the cost of elephants necessary for the work, more rigid requirements as regards working, and increased rate of royalty demanded. Tables are given showing the total output of teak in Burma for the years 1887 to 1904, and of exports of teak from Burma and Siam during approximately the same period.

DISEASES OF PLANTS.

The physiology of diseased plants, L. Montemartini (*Atti Ist. Bot. Univ. Pavia, 2. ser., 9 (1904), pp. 63; abs. in Bot. Centbl., 98 (1905), No. 11, pp. 276, 277*).—A study was made of the respiration, assimilation, transpiration, increase in dry matter, ash, etc., in a number of plants that had been attacked by various plant and animal parasites. Among the plants investigated were grapes, violets, clematis, various grasses, roses, quince, euonymus, etc., the fungi being rusts, mildews, and leaf spots, and the insect attacks being due to mites.

The different parasites studied are said to be able to exert a stimulative effect on the development of their host plants. This is manifest more in the increased respiration than in chlorophyll assimilation, the latter being depressed as respiration is increased. In general the Uredineæ excite a greater chlorophyll assimilation on the part of the host. Transpiration was found uniformly greater in diseased than in sound plants, with the exception of euonymus attacked by *Chionaspis euonymi*. The transpiration under the action of light is increased for a time, after which it markedly diminishes. It also increases whenever assimilation is stimulated. Most of the parasites studied did not seem to have any direct influence on the water or ash content of their hosts, and whatever increase was found was attributed indirectly to the stimulated physiological activity of the plant.

Attention is called to the fact that many poisons exert stimulating effects on plants when dilute, although they are destructive when used in greater proportions. From this the author deduces the hypothesis that the parasites may secrete some poisonous substances, possibly zymases or oxydases, which at first have a stimulating effect on the host plant and which disappear with the progress of the disease.

Plant diseases of Belgium, H. Vanderyst (*Bul. Agr. [Brussels], 21 (1905), Nos. 4, pp. 583-632, figs. 12; 5, pp. 873-908, figs. 7*).—After a general account of the Ustilagineæ, in which their common host plants are enumerated, the life cycle of

the fungi and means for their repression are described. The author takes up the various genera of smuts, describing their species in detail. The work is intended as an account of the diseases of Belgium which are due to fungi, but a considerable number are included that have not yet been reported as occurring in that country.

Annual report of investigations on plant diseases, M. HOLLRUNG ET AL. (*Jahresber. Pflanzenkrank., 7 (1904), pp. VIII + 374*).—A review is given of the literature relating to plant diseases and insect injuries during 1904, about 2,000 articles being noted by abstract or otherwise. The arrangement is similar to that in previous publications (E. S. R., 17, p. 373).

The bearing of Mendelism on the susceptibility of wheat to rust, E. J. BUTLER (*Jour. Agr. Sci., 1 (1905), No. 3, pp. 361-363*).—Commenting upon the conclusions of a previous author (E. S. R., 17, p. 462), the author states that the Mendelian laws may hold good for a given rust in a particular locality, and not where the wheat is exposed to the attacks of a second species of rust or when it is transferred to another locality. A number of instances are cited of varieties of wheat that are reputed to be resistant to rust in one locality which are quite easily affected when transferred to other regions, and vice versa.

The author in defining susceptibility to rust says that it depends on the liability of the leaves to uredospore attack, and that the latent germ, if it exists at all, can do so only in a comparatively small proportion of grains. No wheat is as yet known on which rust may not sometimes appear, so that immune sorts may bear the latent germ as well as susceptible ones.

Experiments with wheat and oats for smut, L. F. HENDERSON (*Idaho Sta. Bul. 53, pp. 15*).—The use of fungicides for the prevention of smuts of wheat and oats has been commonly urged, and the present bulletin was designed not to test the relative efficiency of treatments but to find out, as far as possible, how long grain should be treated to give the best results. It is shown that smut may be controlled by proper treatment, and that formalin solution is better than copper sulphate. Another season's experiments will be required to determine whether the yield per acre is sufficiently greater with oats treated with hot water to pay for the extra trouble over the formalin treatment.

A second series of experiments was carried on to determine the effect of formalin on germination of grain. To test this, wheat was piled upon heavy canvas, thoroughly sprinkled with formalin solution, and shoveled until every kernel was wet, after which the pile was covered with two thicknesses of canvas and allowed to remain for some time. The seed treated with a solution of 1 pt. of formalin to 16 gal. of water and covered for nearly a day was but slightly injured. The seed treated as above and covered for nearly 2 days was seriously affected. Wheat treated by the ordinary formula, 1 pt. of formalin to 50 gal. of water, or even 1 pt. to 25 gal., was not injured at all, although covered for 2 days. It is recommended that in treating grain with formalin the piles should not be covered at all. Injury is believed to be due either to the use of too strong solutions or to the covering of the pile so as to keep the seed moist for 2 days or more.

The flag smut of wheat, D. McALPINE (*Jour. Dept. Agr. Victoria, 3 (1905), No. 2, pp. 168, 169, pl. 1*).—A description is given of attacks of *Urocystis occulta* on wheat. This smut is usually confined to rye, but in Australia seems to be a rather serious pest of wheat. For its prevention the author recommends the use of formalin, the seed to be soaked for 10 minutes in a solution of 1 lb. to 40 gal. of water, after which it is dried and sown.

Potato scab, L. F. HENDERSON (*Idaho Sta. Bul. 52, pp. 8*).—A report is given of a series of experiments to test the relative value of sulphur, formalin, and corrosive sublimate treatments for the prevention of potato scab.

Rolling seed potatoes in sulphur was found to have little if any effect in reducing the amount of scab, and treated potatoes planted in soil from which a scabby crop

was removed the previous year resulted in the production of a scabby crop. Treatment with formalin gave as good results as with corrosive sublimate; and as it is much safer to use than corrosive sublimate, formalin is recommended. The treated potatoes should be planted in new ground and care should be exercised that after treatment they should not be placed in sacks which have previously held scabby tubers.

Potato leaf curl, M. C. COOKE (*Gard. Chron., 3. ser., 38 (1905), No. 978, p. 230*).—The author states that the potato leaf curl, or early blight, as it is known in this country, caused by *Macrosporium solani*, while previously noted, has only recently become a serious pest in England. The appearance of the fungus and its effect upon the host plant are described, and, according to the author, the only conidia commonly occurring in the British specimens are those of the Cladosporium form.

Spraying with ammoniacal copper carbonate or dilute Bordeaux mixture, if commenced sufficiently early, will hold the disease in check.

The cytolytic enzym produced by Bacillus carotovorus and certain other soft rot bacteria, L. R. JONES (*Centbl. Bakt. [etc.], 2. Abt., 14 (1905), No. 9-10, pp. 257-272*).—In an account of studies on the soft rot of the carrot previously noted (E. S. R., 13, pp. 362, 567) the author suggested that the possible action of the bacteria was through the presence of a cytolytic enzym, and the correctness of this supposition has been confirmed by subsequent investigations.

The author believes, as a result of his studies, that the action of the organisms on the tissues of the host plant is shown in the solution of the middle lamellæ of the parenchymatous tissues, and that the organisms do not pass through the undissolved residual walls. The action upon the cell walls being determined as enzymic in nature, he undertook to isolate and study the characteristics of the enzym, separating it by heat, filtration, the use of germicides, diffusion, and precipitation with alcohol. The methods pursued are described at considerable length, after which an account is given of the relation of various conditions to the activity of the enzym. The enzym seems to be a stable compound which persists unchanged for a long time in culture broths and may be preserved indefinitely as a dry precipitate. It is most active at temperatures ranging from 40 to 45° C., and when the temperature was carried to 51° or more the enzym was destroyed in all solutions. Other characteristics of the action of the enzym are described, and comparisons were made between its action and a similar cytolytic action observed with other organisms.

The author has had under observation about 40 strains of organisms isolated in different laboratories from the rotting tissues of cabbage, turnip, cauliflower, kale, iris, etc., and comparative trials have shown that these soft rot organisms, although from different vegetables and widely separated regions, are remarkably similar in enzymic activity. The only exception observed is that found in *Pseudomonas iridis*, which, in the author's opinion, is nonpathogenic under the conditions observed. The others all induce soft rots of various vegetable tissues, and from the cultures of each a cytolytic enzym was secured that was indistinguishable from that produced by *B. carotovorus*. In all of these the action consists in the solution of the middle lamella and ceases before the complete solution of the cellulose layer of the wall, and in all there was an absence of any diastatic action.

The author comments on the classification and nomenclature of cytolytic enzyms, showing the present tendency to use the words pectinase and cellulase vaguely as synonymous with cytase. The author suggests that they be restricted to more exact usage and that cytase and cytolyst be retained as convenient and satisfactory terms for use in the broader sense to include in general all enzyms capable of hydrolyzing the cell walls.

Cactus scab, G. MASSEE (*Gard. Chron., 3. ser., 38 (1905), No. 972, p. 125, fig. 1*).—A disease caused by a parasitic fungus has long been known to cultivators of cacti,

but until recently the fruiting form had not been recognized. A recent investigation showed the parasite to be *Diplodia opuntiæ*, first collected on *Opuntia nana*, in Northern Italy. The injury caused by the fungus is sometimes severe, the black minute, wart-like outgrowths often covering a considerable area and the surrounding tissue becoming discolored.

Constitutional diseases of fruit trees, A. G. CAMPBELL (*Jour. Dept. Agr. Victoria, 3 (1905), No. 6, pp. 463-465*).—Brief descriptions are given of a number of diseases of apples and apricots, which, so far as known, are not due to the presence of any parasitic growth.

The diseases described are watercore, bitter pit, and crinkle, a name given a rather serious disease of the apple, in which the cells just beneath the skin, particularly about the calyx, die and collapse, causing a sunken, discolored area. Some varieties seem especially subject to this disease, the Rome Beauty being particularly liable to this trouble. The disease of apricots described under the name smudge is characterized by the death of the cells in large irregular patches, over which the skin sinks, leaving dark blotches on the surface.

For the successful treatment of most of these troubles attention should be paid to the proper cultivation of the trees, drainage, fertilizers, etc.

Black spot canker and black spot apple rot, W. H. LAWRENCE (*Jour. Mycol., 11 (1905), No. 78, pp. 164, 165*).—The black spot canker fungus (*Macrophoma curvispora*), like the bitter rot fungus, causes a disease of both the tree and fruit. It differs, however, from bitter rot in that the canker stage does by far the greater amount of injury. This stage has become very prevalent in certain parts of British Columbia, Oregon, and Washington, causing considerable loss.

In January, 1903, the author noticed numerous decaying apples among stored fruit, in which a few pustules were present in decaying areas, and later the epidermis overlying each pustule split, exposing a mass of creamy white spores. These spores were identical with those previously recognized as typical of the black spot canker fungus except that they were slightly larger. Inoculation experiments were carried on to determine the relation of the canker and the rot, and it was found that the fungus is parasitic in the bark and sapwood of the trunk and branches and also on the stored fruit of the cultivated apple.

The first indication of the presence of the disease in the fruit is a slight discoloration of the flesh of the apple just beneath the epidermis. The flesh becomes a light brown color and as more becomes involved the color changes to a deep brown. The epidermis takes on a corresponding change of color, and the decaying spots become depressed, dry, and leathery. In many cases the decaying areas are found near the basin and calyx ends of the fruit, being associated with codling moth burrows, bruises, etc., but more than 50 per cent of the specimens examined showed that the fungus entered directly through the epidermis of the fruit.

Moisture and temperature were found to exert marked influence on the development of the rot. In cool, dry weather the spots increase in size, but few pustules are developed. During cool, damp weather an abundance of pustules is formed. The tendency for certain varieties of fruit to decay more rapidly than others was observed.

A technical description of the fungus on both the tree and the fruit is given, based upon the author's observations.

Pear blight, cause and prevention, R. I. SMITH (*Ga. Bd. Ent. Bul. 18, pp. 109-126, pls. 2*).—According to the author, pear blight in 1905 caused an unusual amount of injury in both pear and apple orchards, in some localities practically destroying the crop, while in others from 50 to 75 per cent of the blossoms were destroyed by the form of the disease known as blossom blight. By special arrangement with this Department cooperative experiments are being carried on in the nature of demonstration work to show the possibility of controlling this disease.

An account of the cause and prevention of pear blight, by M. B. Waite, is given, the article being copied from the Yearbook of this Department for 1895 (E. S. R., 8, p. 796). The bulletin concludes with a brief account of the leaf blight of pear and quince, caused by the fungus *Entomosporium maculatum*.

A new disease of olives, A. MAUBLANC (*Bul. Soc. Mycol. France, 20 (1904), pp. 229-232, figs. 7; abs. in Bot. Centbl., 98 (1905), No. 12, p. 299*).—A brief account is given of a disease of olives due to *Macrophoma dalmatica*. This fungus forms its pycnidia in brown spots on the surface of the fruit, which extend to the center, resembling in a way the puncture of insects. The fruit in the process of its development isolates these diseased areas by forming about them a corky layer.

Some causes of the destruction of vines in Tunis, L. RAVAZ (*Bul. Agr. Algérie et Tunisie, 11 (1905), No. 19, pp. 434-443*).—A report is given of the investigations of a commission appointed to determine the cause of the rapid destruction of grapevines over quite an extended area in Tunis.

Studies made in the vineyard and laboratory failed to show the presence of any fungus or other organism, and the author finally concluded that the trouble was chiefly due to the heavy overbearing of young vines, and the history of a number of vineyards tended to confirm this conclusion. Under the condition of grape growing in Tunis 3 and 4 year old vines produce such abundant crops that the vines are permanently weakened and finally die. The author suggests the removal of all dead stocks, replacing them with new ones, and by attention to culture, the use of fertilizers, and irrigation during the first few years after planting the losses attributed to this trouble can be avoided.

Studies on the gray rot of grapes, G. DE ISTVÁNFFI (*Ann. Inst. Cent. Ampélol. Roy. Hongrois, 3 (1905), No. 4, pp. 183-360, pls. 8, figs. 15*).—The results of an extended series of biological and mycological studies on *Botrytis cinerea* or *Sclerotinia fuckeliana* are given.

Germination experiments are reported upon at length, in which the normal germination of the fungus is described and the effect of various physical agents and chemical compounds shown. The author gives a general account of the sclerotia of the fungus, describing their growth on different parts of the vine, behavior in pure cultures, etc., as well as practical suggestions for combating the disease, which at times becomes epidemic in its nature. In the studies reported the polymorphism of the fungus is shown and the different forms of growth and reproduction are described. The author has traced the life cycle of the fungus, adding a number of important discoveries relating to it.

Among considerations of practical importance in combating the disease, the author says that the Botrytis form of the fungus lives saprophytically on fallen leaves, twigs, fruits, etc., during the early season, but the conidia develop with great rapidity on the arrival of warm, moist weather, and when transferred to the growing foliage, live parasitically. The Botrytis attacks the ripening fruit in autumn, often causing great loss. Sclerotia are formed abundantly on the grapes and also on the cuttings made during the summer. If the fungus is present upon the cuttings when stratified the disease will be carried over the winter. The mycelium is also able to pass the winter in the young shoots, so care should be exercised in selecting cuttings either for layering or grafting that they are not affected.

In stratifying cuttings the author recommends wetting the twigs, sand, benches, boxes, etc., with a 5 per cent solution of calcium bisulphid, after which all are to be well dried in the sun before being packed away. In the spring of the year the sclerotia can easily be found on the fallen leaves, twigs, dried grapes, etc., where they germinate about June 1. All débris in vineyards should be collected and burned in the autumn. Thoroughly washing the vines with a 5 per cent solution of calcium bisulphid during late autumn or early spring, and alternate applications during the growing season of 1 per cent solutions of Bordeaux mixture and powdered sulphur

with powdered bisulphid of soda are recommended as preventive treatments. The application of dry fungicides is said to be preferred to ordinary sprayings as being less liable to scatter the spores of the fungus.

The must from diseased grapes should receive the same treatment as is recommended above for cuttings and dried fruits.

Experiments in controlling black rot in Loire, L. ROUGIER (*Rev. Vit., 24 (1905), No. 628, pp. 713-719*).—Descriptions are given of a number of experiments carried on for the prevention of black rot of grapes. The use of acetic acid added to fungicides has been recommended, and the author undertook to determine the amount of this acid that would be dangerous to plant growth. It was sprayed upon grapes in various concentrations alone and with neutral copper acetate. As a result of the investigations the author finds that the disease could be successfully controlled by the use of an acidulated copper acetate.

A new disease of grapes, G. DE ISTVÁNFFI (*Ann. Inst. Cent. Ampélol. Roy. Hongrois, 3 (1905), No. 3, pp. 167-182, pl. 1*).—In 1900 a disease of grapes was observed in Hungary that superficially resembled an attack of black rot on the foliage. An examination showed that it was in no way associated with the black rot, but was due to a distinct fungus, *Phyllosticta bizzozeriana*. Since its first observation the disease has spread, but most injury is noted in the original center. The fungus attacks the leaves only, never being observed on the fruit, and it has no relation to the black rot, but is often associated with the anthracnose, the two fungi seeming to work together.

Frequent and thorough treatment with fungicides such as are recommended for grape mildew is suggested, and on account of the association with anthracnose, late autumn and early spring treatments for preventing anthracnose are advised. All European varieties of grapes as well as the variety Isabella seem subject to attack. A technical description of the fungus is given, and its relation to other species of Phyllosticta is discussed.

The bud rot of cocoanuts, J. H. HART (*Trinidad Bot. Dept., Bul. Misc. Inform., 1905, No. 48, pp. 242, 243*).—A summary is given of the author's observations regarding the bud rot disease of cocoanuts. The evidence presented seems to indicate that the disease has been present on the plantation examined for a great many years, as there is a succession of trees which have been planted on areas vacated by the destruction of former occupants.

A preliminary microscopical examination showed bacteria present in great quantity, especially in the heart or growing portion of the tree. The specimens examined were found to be infected from the ground upward, and when the stem was cut through a ring of red discoloration was found between the woody exterior and the interior parts of the stem. This discoloration became more prominent as it reached the growing points and appeared especially to affect the base of the leaf stalks and the spathes inclosing the flowering organs. Eventually these portions become badly infested, the leaves fall, and the tree dies.

From previous descriptions of diseased cocoanut trees from various sources the author believes that there is little doubt as to the identity of the disease under examination. So far he has been unable to find that there was any relation between the occurrence of the disease and the injury done by the palm beetle (*Rhyncophorus palmarum*). In addition to bacteria, numerous fungi are to be found in the diseased stems, and further investigations will be necessary to determine the true cause of the disease and methods for its control.

Cacao diseases (*Bul. Dept. Agr. [Jamaica], 3 (1905), No. 12, p. 270*).—A brief account is given of the disease of cacao due to the fungus *Phytophthora omnivora*. The presence of this fungus may be recognized by the darkening of the pods and the occurrence of a delicate white mold on the outside.

To prevent the disease it is suggested that the affected pods be gathered and burned, or so deeply buried that the spores will not be brought to the surface. In order to prevent spread to other pods the trees should be well sprayed with Bordeaux mixture.

The cocoa disease in Surinam (*Trop. Life, 1 (1905), No. 1, p. 12*).—A brief account is given of the spread of the cacao disease in the West Indies, and a letter from Dr. Van Hall is noted, in which it is stated that the witch-broom disease has been under investigation by him for about 9 months, but as yet he has been unable to ascertain definitely the means of its dissemination. It is believed probable that the spores are spread principally by the wind. Dr. Van Hall states that while the disease first appeared in Surinam, it is now known as occurring in Demerara, where it is spreading, and will probably cause great loss. In Surinam this disease has reduced the export from 31,630 bags of 100 kg. each in 1901 to 8,540 in 1904.

The silver-leaf disease (*Gard. Chron., 3. ser., 38 (1905), No. 971, p. 111*).—A brief note is given on inoculation experiments carried on by Professor Percival at Reading.

If by a process similar to budding a small fragment of the fungus or portion of the leaf affected with the characteristic discoloration be inserted in the bark of plum trees, after some time, varying according to season, the silvery appearance shows itself in the foliage where before all was green. This peculiar appearance is due to the detachment or raising of the epidermis of the leaves from the adjacent tissue. So far no fungus has been found in the leaves, and it is intimated that probably the disturbance is caused by some ferment or enzym secreted by the fungus, which reaches the leaves from the wound.

The disease seems to be confined to the stone fruits, and it occurs under glass as well as in the open air. The only remedy at present known is to cut away the affected branches and induce the tree to make new growth, but experiments have shown that this is not at all satisfactory.

Combating the pine leaf cast, SCHALK (*Forstw. Centbl., n. ser., 27 (1905), No. 11, pp. 561-570, pl. 1*).—The pine leaf cast, due to the fungus *Hysterium pinastri*, is described and notes given on experiments carried on for its control.

The author claims that even in regions where the disease is very prevalent it can be prevented by thorough spraying and the proper use of fertilizers. A single annual spraying in the seed bed will usually be sufficient, and if carried on for 4 years strong plants will be produced and the dominant ones will be free from disease. In the nursery rows at least 2 sprayings should be given the trees annually. This, together with proper fertilizers, will enable the young plants to withstand the leaf cast.

Winter treatment against fungus diseases, L. DEGRULLY (*Prog. Agr. et Vit. (Ed. l'Est), 26 (1905), No. 49, pp. 641, 642*).—The author points out editorially the advantage to be obtained by the use of strong solutions of fungicides as winter treatment against various grape diseases, and he recommends treating the vines during the dormant season with strong solutions of potassium sulphate, calcium bisulphite, and iron sulphate for the prevention of powdery mildew, or with solutions of copper sulphate and bichlorid of mercury for preventing downy mildew, black rot, and powdery mildew.

Fungicides and their use in preventing diseases of fruits, M. B. WAITE (*U. S. Dept. Agr., Farmers' Bul. 243, pp. 32, figs. 17*).—The object of this bulletin is to give the principal formulas for fungicides, together with brief descriptions of their methods of preparation, and a summary of the principal diseases of fruits for which satisfactory remedies have been found.

ENTOMOLOGY.

Proceedings of the Entomological Society of Washington (*Proc. Ent. Soc. Wash., 7 (1905), No. 2-3, pp. 65-152, figs. 12*).—In this number the following papers are included:

Descriptions of New American Spiders; New Trichoptera from Japan; Descriptions of Some New Mites, by N. Banks; Illustrations of an Undetermined Coleopterous Larva; The Spread of *Sphæridium scarabæoides*, by H. S. Barber; Kirby's Catalogues of Orthoptera; The Species of the Genus Chimarocephala and Descriptions of Two New Species of Californian Orthoptera, by A. N. Caudell; Notes on *Eulecanium folsomi*, by T. D. A. Cockerell; The Linnæan Genera of Diptera, by D. W. Coquillett; Larva of *Castnia licus;* A Few Notes on the Strecker Collection, by H. G. Dyar; *Catogenus rufus*, a Coleopterous Parasite, by W. F. Fiske; Notes on Some Mexican Scolytidæ, With Descriptions of Some New Species; Notes on Scolytid Larvæ and Their Mouth Parts, by A. D. Hopkins; A New Species of Donacia, by F. Knab; Some Notes on the Provancher Megachilidæ, by E. S. G. Titus; Description of a New Species of Desmocerus With a Synoptic Table of the Genus, by J. L. Webb; and A New Enemy of Timothy, by F. M. Webster.

The enemy of timothy reported from various States from New York to North Dakota appears to be a species of Isosoma. The larva works in the joints of timothy in much the same manner as does *I. grande*. A number of parasites were raised from the insect. The pest causes a shortening of the stem and shrinkage of the seed crop, and is, therefore, considered a serious enemy of timothy.

Thirty-sixth annual report of the Entomological Society of Ontario (*Ann. Rpt. Ent. Soc. Ontario, 36 (1905), pp. 143, figs. 74*).—This report contains an account of the proceedings of the forty-second annual meeting of the society, held at Guelph, Ontario, October 18 and 19, 1905.

During the different meetings of the society various papers on economic entomology were read, some of which are mentioned in the following notes: A number of reports were presented on the status of insect pests in different districts. In this report it appeared that the woolly aphis, zebra caterpillar, cottony maple scale, wire worms, and codling moth were unusually abundant. The tussock moths were discussed by T. W. Fyles and H. H. Lyman. These moths do an unusual amount of damage to ornamental and shade trees, causing considerable interest to be developed in methods of extermination. Notes were presented on the entomological conditions in North Carolina, by F. Sherman, jr.

W. Lochhead read a paper on experiments against the San José scale in 1905. It is stated that in Ontario the lime-sulphur wash has been successfully used, made according to the formula 20-15-40. Various other combinations of these ingredients have also been used in the preparation of washes with or without boiling. Little or no difference was observed in the effectiveness of the boiled and unboiled washes. In order to prevent the great multiplication of the San José scale in the fall, it is necessary that the insecticide should adhere to the trees for long periods.

J. B. Smith reviewed briefly the work on mosquitoes in New Jersey, and reports were given of the councils of the various branches of the society.

A number of other papers were read, some of which are mentioned in the following list: Insects as nature studies, by S. B. McCready; forest insects, by T. W. Fyles; insects injurious to Ontario crops in 1905, by J. Fletcher; an entomological record for 1905, by J. Fletcher; injurious insects of the flower garden, by A. Gibson; forest entomology, by E. J. Zavitz; phlox mite, spruce saw-fly, and bumblebees that fertilize the red clover, by T. D. Jarvis; injurious insects of 1905, in Ontario, by W. Lochhead.

Tenth annual report of the State entomologist of Minnesota, 1905, F. L. Washburn (*Ann. Rpt. State Ent. Minn., 10 (1905), pp. 168, pls. 2, figs. 163*).—In this

report the author carries out the apparent intention of his predecessor, Doctor Lugger, in publishing a monograph on the diptera of Minnesota. Brief notes are given in a preliminary statement on the special features of insect outbreaks during the year. The Hessian fly and chinch bug occurred in much smaller numbers than ordinarily. Alfalfa was greatly injured by the red-legged grasshopper. Various other species of insects caused damage, particularly cottony maple scale, stalk borer, cotton boll-worm in corn, white grubs, etc.

As already indicated, the major part of the report is occupied with a monograph on the diptera of Minnesota. The author describes in considerable detail the biology and anatomy of this order of insects, and presents notes on the habits, life history, and means of combating all known injurious flies in the State, together with short accounts of other diptera not of economic importance. The families which the author discussed include among others the Tipulidæ, Culicidæ, Chironomidæ, Cecidomyidæ, Simuliidæ, Syrphidæ, Oscinidæ, Oestridæ, Sarcophagidæ, Muscidæ, Hippoboscidæ, etc.

Diptera of Minnesota: Two-winged flies affecting the farm, garden, and stock and household, F. L. Washburn (*Minnesota Sta. Bul. 93, pp. 7–168, pls. 2, figs. 163*).—The material in this bulletin has already been referred to from another source (see above).

Report on economic zoology, F. V. Theobald (*Jour. Southeast. Agr. Col. Wye, 1905, No. 14, pp. 38–158, figs. 43*).—In this report the animal and insect pests are arranged according to the plants or animals which they affect.

Among the pests of domesticated animals mention is made of serrated dog tapeworm, lungworms in sheep, liver fluke, *Rhyphus fenestralis*, etc. The last-named species is reported as injurious to bees. A large number of fruit insects are discussed, with notes on their appearance, habits, and life history. Among these may be mentioned cherry sawfly, apple-plant louse, strawberry aphis, and woolly aphis. Some of the more important garden insects discussed are *Otiorhynchus picipes* on the raspberry, Colorado potato beetle, cabbage maggot, cabbage aphis, carrot aphis, tarnished plant bug, rose scale, etc.

Forest tree insects are also discussed, with particular reference to the willow weevil, larch leaf-miner, giant-willow aphis, elder aphis, and felted beech coccus. Notes are also given on some of the insect pests of food products, horse flies and other insects injurious to man, and a number of insect pests reported from various English colonies.

Report on injurious insects and plant diseases for 1904, W. M. Schøyen (*Beretning om Skadeinsekter og Plantesygdomme i 1904. Christiania: Grondahl & Sons, 1905, pp. 26, figs. 17*).—The insects which caused injury to field and garden crops during the year under report are briefly discussed. Among the more important pests mention may be made of grain aphis, timothy fly, cabbage maggot, crane flies, red spider, *Aryresthia conjugella*, apple scab, currant sawfly, currant mite, etc.

Injurious insects, F. Corboz (*Chron. Agr. Vaud, 18 (1905), Nos. 13, pp. 307–310; 14, pp. 335–342*).—Brief economic and biological notes are given on San José scale, red spider, nematodes, and predaceous insects.

The entomological section, L. Bostock and C. B. Simpson (*Transvaal Agr. Jour., 4 (1905), No. 13, pp. 162–184, pls. 2*).—A brief report is made on a survey made with reference to the distribution and economic importance of mosquitoes and on means of destroying them. Notes are also given on two migratory locusts (*Acridium purpuriferum* and *Pachytyus sulcicollis*). Arrangements are being made for an elaborate campaign against these pests.

Entomological investigations in Central Asia, J. Sahlberg (*Öfvers. Finska Vetensk. Soc. Förhandl., 46 (1903–4), No. 1, pp. 1–38*).—The most abundant insects observed in various parts of Central Asia during visits to those countries are mentioned, with brief notes on their habits.

Insects of the garden, R. H. PETTIT (*Michigan Sta. Bul. 233, pp. 77, figs. 65*).—The author has undertaken the publication of bulletins dealing with insects which affect different classes of farm and garden crops, and this is the second bulletin of the series. The insects considered in the bulletin are grouped under the plants affected. All of the common garden crops are treated, with notes on their most important insect enemies, the life histories of these pests, and means of combating them. Directions are also given for the preparation of various insecticides. The bulletin is provided with an index.

Observations and short notes on the chief insect enemies of garden crops, I. VASILEV (*Trudui Byuro Ent.* [*St. Petersb.*], *6* (*1905*), *No. 4, pp. 55, pls. 7, figs. 17*).—The insects discussed in this report are classified according to their systematic position. Biological and economic notes are given on *Zeuzera pyrina*, gypsy moth, brown-tail moth, *Hibernia defoliaria*, codling moth, apple curculio, *Epicometis hirta*, fruit-tree bark-beetle, apple-tree aphis, woolly aphis, oyster-shell bark-louse, etc.

A monograph of insect injuries to Indian corn, II, S. A. FORBES (*Rpt. State Ent. Ill., 23* (*1905*), *pp. XXXIII + 273, pls. 8, figs. 234*).—The first part of the author's monograph of corn insects (E. S. R., 8, p. 501) treated of insects injurious to the planted seed and to the roots.

The present part contains an account of insects which attack various parts of the corn plant above ground. The author and his assistants have devoted much time and energy to the study of all insects found on corn and particularly to the elaboration of suitable remedies for these pests. In the present part of the monograph on corn insects a large number of species are discussed and are classified for convenience into the more important, less important, and unimportant species. The detailed discussion of different species is preceded by an account of the adaptation and reaction of corn to its insect visitors, general effect of insect injuries, peculiar features of injury to different parts of the plant, and similar subjects.

The insects discussed by the author are too numerous for individual mention in this abstract. They include various species of cutworms, yellow bear caterpillars, webworms, June beetles, flea beetles, oyster beetles, leaf hoppers, grasshoppers, as well as ants, flies, spanworms, snout beetles, plant bugs, plant lice, red spiders, etc. A particularly valuable part of the monograph from the standpoint of the practical farmer is a key for the identification of all species concerned and based on the kind of injury which the different insects cause. This key occupies pages 225–233 and should enable the farmer to identify at once the insect pest with which he has to deal. An elaborate bibliography of literature relating to corn insects is appended to the report (pp. 234–273).

Root maggots and how to control them, F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Circ. 63, 2. ed., pp. 7, figs. 5*).—The seed-corn maggot (*Pegomyia fusciceps*) attacks corn, beans, and many other vegetables. There are apparently several generations annually.

Whatever insecticide treatments are chosen they should be applied before the eggs are laid. A mixture of sand and kerosene may be placed at the base of plants for the purpose of keeping the flies from depositing their eggs. The carbolic emulsion may be used for the same purpose, made according to the formula calling for 1 lb. of soap boiled in 1 gal. of water and ½ gal. of crude carbolic acid diluted before use with 35 to 50 parts of water. Mineral fertilizers are of some value as deterrents, and good results have also been obtained from the tedious method of hand picking.

The cabbage maggot is most injurious in the northern tier of States and in Canada. It may also be controlled by the use of carbolic acid emulsion, hand picking, fall plowing, clean cultivation, the use of gas lime, carbon bisulphid, or tarred-paper cards placed about the plants. The imported onion maggot (*Pegomyia cepetorum*) attacks the bulbs of the onion, causing subsequent decay. The insect is briefly

described. The remedies already mentioned for other root maggots may be applied in controlling this species.

Injurious bugs and cicadas on cotton, T. KUHLGATZ (*Mitt. Zool. Mus. Berlin, 3* (*1905*), *No. 1, pp. 23–114, pls. 2*).—A considerable number of species of these insects are discussed from the standpoint of their distribution, biology, and systematic position in the order of insects. Particular attention is given to *Tibicen dahli*, *Tectocoris lineola cyanipes*, *Dysdercus sidæ*, *D. cingulatus*, *D. superstitiosus*, *D. cardinalis*, *D. suturellus*, *D. andreæ*, etc. The habits and life history of each species are briefly described and detailed notes are given on the distribution of the species. A bibliography of the subject is appended to the article.

The boll weevil and cotton crop of Texas, E. D. SANDERSON (*Austin: Dept. Agr., 1905, pp. 28, pls. 7*).—The author reviews previous estimates which have been made since 1894 of the amount of damage done by the boll weevil.

Statistics were collected on the cotton acreage of Texas from 1899 to 1904 and on the variations in the acreage and in the yields which may be attributed to the work of the boll weevil. In connection with this discussion maps are presented showing the distribution of the weevil. It is believed that since its introduction into Texas the boll weevil has destroyed 2,000,000 bales of cotton with an estimated value of one hundred million dollars. The weevil is seldom extremely injurious in the southern part of Texas if stubble cotton is not allowed to remain over winter. Apparently the weevil does not promise to become very dangerous in the western cotton counties.

The remedy for the boll weevil, W. NEWELL (*Crop Pest Com. La. Circ. 3, pp. 20, figs. 5*).—Maps are given showing the gradual advance of the boll weevil into Louisiana with reference to the effects of cold rainy winters upon the pest. It is believed, however, that the boll weevil will be able to winter successfully in the cotton regions of Louisiana. The cultural method is considered the only efficient remedy for controlling the boll weevil. This consists in early planting, the use of varieties which mature quickly, the application of fertilizers, thorough cultivation, and destruction of cotton plants in the fall as well as other material in which the beetles may hibernate.

The control of the codling moth and apple scab, C. L. MARLATT and W. A. ORTON (*U. S. Dept. Agr., Farmers' Bul. 247, pp. 21, figs. 9*).—The codling moth and apple scab are considered the chief insect enemy and fungus disease of the apple. They may be controlled by the application of a combined insecticide and fungicide and are, therefore, treated together in this bulletin.

Notes are given on the habits and life history of the codling moth and upon the biology of the apple-scab fungus. Directions are given for banding trees to catch codling-moth larvæ and for the preparation of Paris green and other arsenicals as well as of Bordeaux mixture. It is recommended that in controlling these two pests the first application be made just after the leaf buds have unfolded, the second just after the petals fall, and the third and fourth at intervals of about 15 days. The first application need not contain Paris green, but the other three should be made with a combination of Paris green and Bordeaux mixture.

Practical suggestions for codling moth control in the Pajaro Valley, W. H. VOLCK (*California Sta. Circ. 14, pp. 11, fig. 1*).—In the Pajaro Valley considerable difficulty has been experienced in fighting the codling moth on account of the unusual prevalence of dews, which dissolve away the insecticides sprayed upon the trees.

Paris green was found to cause considerable injury to the trees, even after it had previously been washed so as to remove the soluble arsenic. In order to prevent the action of the dew upon Paris green it was coated with heavy oils and other waterproof materials. These coatings, however, were ultimately destroyed. Lead arsenate was found to possess a high weather-resisting property and is, therefore,

suited for this work. Considerable difference was noticed in the killing power of different samples of lead arsenate and in their action upon the foliage. Thorough spraying is needed in order to cover all parts which may be attacked by the codling moth.

Since the broods seem to overlap one another without leaving any interval between them, it is considered necessary to spray at short intervals from April until October. The author suggests 9 applications during the season on April 10 and 30, May 17, June 17, July 10, August 1 and 21, September 12, and the first week of October. These applications may be expected to yield a crop of apples from 95 to 98 per cent free from codling moth, at a total cost of about 32 cts. per tree.

The gypsy moth in New Hampshire, E. D. SANDERSON (*New Hampshire Sta. Bul. 121, pp. 81-104, figs. 11*).—The history of this moth in Massachusetts is briefly outlined and notes are given for the purpose of comparing the life history of the gypsy moth and brown-tail moth. In 1904 an examination of the southeast coast of New Hampshire showed that the gypsy moth was present in small numbers in all of the towns from the Massachusetts line to Portsmouth. A map is given showing the present distribution of the gypsy moth in New Hampshire. The life history, habits, food plants, natural enemies, and methods of combating this pest are described.

The brown-tail moth in New Hampshire, E. D. SANDERSON (*New Hampshire Sta. Bul. 122, pp. 105-132, figs. 20*).—This moth was first recognized in Massachusetts in 1890 but did not attract attention until 1897. It has spread with great rapidity, and in 1899 was first found in New Hampshire in the town of Seabrook. At present it is distributed over all of the southeastern part of the State. The life history, habits, and practical methods of combating this pest are described. Notes are also given on its natural enemies and on the injury caused by the nettling hairs of the caterpillar.

The gypsy moth and the brown-tail moth, W. E. BRITTON (*Connecticut State Sta. Bul. 153, pp. 11, figs. 8*).—The gypsy moth has been found at Stonington, Connecticut, and an attempt is being made to eradicate it. A brief account is presented of the habits and life history of the gypsy moth and brown-tail moth with practical methods of controlling these pests.

Some experiences with insecticides for the San José scale, C. O. HOUGHTON (*Delaware Sta. Bul. 74, pp. 16*).—A considerable variety of proprietary remedies were used as well as kerosene emulsion and lime-sulphur-salt washes. The applications were made for the most part in the spring but in ordinary instances in the fall.

Peach trees were sprayed with a mixture containing 15 lbs. each of lime, sulphur, and salt per 45 gal. of water boiled by steam for ½ hour. Various other formulas for the lime-sulphur-salt wash were tested, both for boiling by steam and for self-boiling caustic washes. Trees sprayed in the fall when examined during the next spring showed no living scales in the case of those which had been treated with the boiled wash and only a few of those treated with the unboiled wash. Both forms of the wash had largely been washed off the trees by February 13, little difference being observed in the adhesive power of the boiled and unboiled washes.

The chief advantage of using oil sprays is that these materials spread more rapidly over the trees but they have the disadvantage that it is not readily apparent whether all parts of the tree have been covered or not. The lime-sulphur washes gave satisfactory results in all cases and the author, therefore, recommends their use as well as that of kerosene emulsion.

The San José scale, W. NEWELL (*Crop Pest Com. La. Circ. 4, pp. 42, figs. 15*).—The introduction and spread of the San José scale in Louisiana is attributed to the fact that no quarantine system against fruit-tree pests has been in operation in the State until recently.

The San José scale is described in its various stages and historical notes are given on the distribution of the pest and upon its food plants. An account is also presented

of the development and life history of the San José scale and of the means by which it is distributed. Evidence was obtained in one case that the San José scale may be spread by means of wagons and farm implements. In applying artificial methods for controlling San José scale the chief reliance of the fruit grower should be placed in lime-sulphur-salt wash.

The formula for this insecticide recommended by the author calls for 21 lbs. lime, 18 lbs. sulphur, and 50 gal. water. This mixture should be boiled for 35 minutes or more. Where boiling is inconvenient the use of caustic soda may be depended upon to produce a mixture nearly as good as the boiled lime-sulphur wash. Applications should be made in Louisiana in the winter. Brief notes are given on insecticide apparatus and on summer treatment, where it appears to be necessary.

Spraying for the San José scale, J. S. Houser (*Ohio Sta. Bul. 169, pp. 139–155, pls. 6*).—A large number of formulas were used for boiled lime-sulphur-salt washes in which the amount of lime varied from 15 to 31 lbs., the amount of sulphur from 7½ to 16⅝ lbs., the amount of salt from 15 to 16 lbs. per 50 gal. of water for winter applications, while for summer use lime-sulphur washes were used in which both the lime and sulphur varied from 1 to 10 lbs. per 50 gal. of water. Spring treatment was also given, using self-boiled washes containing from 15 to 32 lbs. of lime, 8 to 16 lbs. of sulphur, and 4 to 12 lbs. of lye or caustic soda per 50 gal. of water.

Of the 13 different formulas used for boiled lime-sulphur-salt washes all of those which contain 15 lbs. or more of lime and sulphur per 50 gal. of water gave satisfactory results in all cases. Salt seems to add nothing to the persistency of the wash nor to its effectiveness, and the same was found to be true of copper sulphate and a large excess of lime. Copper sulphate added to the mixture had apparently no additional fungicidal effect. The addition of glue was of no value in making the wash adhere longer.

Con-Sol was tested in the treatment of San José scale, but appeared to be of no value. The use of kerosene limoid did not give satisfactory results. Scalecide is easily applied and appears not to be irritating to the skin. Better results were obtained from this than from any of the other proprietary insecticides.

The author prefers the use of the lime-sulphur mixture containing at least 15 lbs. per 50 gal. of water. This insecticide can not be applied to trees while they are in foliage. The prevalence of leaf curl in orchards is greatly checked by the use of lime-sulphur washes. The preferred formula is 15 to 20 lbs. lime and 15 lbs. sulphur in 50 gal. of water boiled for 45 minutes and applied in the spring or fall. The most satisfactory method of boiling is found in the use of steam.

San José scale, A. B. Cordley (*Oregon Sta. Bul. 88, pp. 15, pls. 5*).—The lime-sulphur-salt wash is considered the best spray for cleaning up trees, in addition to its power of holding the San José scale in check when applied once annually. The attention of orchardists is called to the fact that the wash can not be used as a substitute for Bordeaux mixture when the trees are in leaf, but should be applied as a winter treatment only.

Notes are given on the food plants, appearance, development, and distribution of the San José scale. The formula preferred in Oregon for the lime-sulphur-salt wash is 1-1-1-3, and it is recommended that the mixture be boiled for at least 1 hour. The natural enemies of San José scale can not be depended upon in Oregon for controlling the pest. A number of experiments were carried on with lime-sulphur-salt in various forms, some containing caustic soda and copper sulphate. The scales were not completely eradicated in any case, but since the spraying was done on badly infested trees, the effect of the lime-sulphur-salt wash was considered satisfactory.

Acariosis of grapes, H. Faes (*Chron. Agr. Vaud, 18 (1905), No. 16, pp. 379–400, pl. 1, figs. 6*).—The nature of the disease referred to under these names has often been misunderstood. The diseases are due to attacks of *Phytoptus vitis*, a mite which

inhabits the scales about the leaf buds and later causes a brown and sickly appearance in the leaf.

In combating this disease the author has had good results from the use of a mixture containing 2 per cent of soap and 1 per cent of a strong decoction of tobacco. In other experiments a 3 per cent solution of potassium permanganate and a 4 per cent solution of lysol or a mixture of soap and carbolic acid proved effective. It is recommended, however, that in a case of serious infestation the badly diseased vines be removed and destroyed and the others thoroughly treated.

Strawberry crown girdler, EDITH M. PATCH (*Maine Sta. Bul. 123, pp. 205–230, pls. 4*).—Complaints were made in a number of instances of large numbers of *Otiorhynchus ovatus* in houses, where they became a general nuisance. The insect appeared to be migrating or seeking a place for hibernation. They occurred in large numbers during the last part of June and the first part of July.

The larvæ of this insect were found feeding on the roots of *Poa serotina*, but in greatest numbers on strawberries. In one locality 200 larvæ and pupæ were dug up in 3 sq. ft. of infested strawberry bed. The beetles also feed on apples, cauliflower, red clovers, lawn grass, elm leaves, cotton-wood leaves, and various other plants. Little hope can be entertained of controlling them by the use of arsenate of lead and other arsenicals, and it is too difficult to apply the insecticides so as to destroy any large number of them. Camphor gum and sulphur were tried as repellents in keeping the beetles out of houses, but without success.

Notes are also given on a number of insects observed during the year, especially tussock moth, red-humped caterpillars, stalk borer, cherry tortrix, rose chafer, carpet beetle, wireworms, brown-tail moth, and nematode worms.

Caterpillars on oaks, C. W. WOODWORTH (*California Sta. Circ. 18, pp. 4*).—The live oaks in the vicinity of California Bay are seriously attacked by caterpillars, particularly *Phryganidia californica* and tent caterpillars belonging to the genus Malacosoma. *Phryganidia californica* occurs only in California and is the only representative of its family in America. It lays its eggs on the underside of the leaves of live oaks.

This pest may be combated by spraying with Paris green at the rate of 1 lb. per 2 gal. of water. The time for spraying is when the moths are seen in large numbers about the trees, for the reason that the eggs hatch soon afterwards. In the case of tall trees ladders will be necessary in order to apply the spray to the topmost branches. About 6 species of the genus Malacosoma, commonly known as tent caterpillars, attack the live oak, but also feed on other trees. They can best be controlled by destruction in the spring while they are still in their nests.

Dust and liquid spraying, C. P. CLOSE (*Delaware Sta. Bul. 72, pp. 23*).—The advantages of dust spraying are that the necessary apparatus is quite simple and inexpensive, the bulk of prepared material is small, and the material is more agreeable to handle than when in a wet form. The chief disadvantages are the impossibility of using the material during high wind or in the middle of the day.

Various methods are given for preparing and mixing dust sprays. The author tried a mixture containing lime, pulverized copper sulphite, Paris green, and sulphur. The best time for using dust insecticides is early in the morning of quiet days. The dust spray adheres to foliage almost as well as liquid sprays. A detailed account was given of the results obtained from the use of dust sprays, particularly in the treatment of apple trees for codling moth. The effectiveness of dust and liquid sprays for this purpose appeared to be nearly equal, the variation in the number of wormy apples being too small to indicate any decided advantage in favor of either method.

The author recommends the use of a liquid spraying outfit on level land where water is readily available. If, however, water is scarce and the ground on which the orchard is planted very uneven it may be a simpler and less expensive matter to spray by means of the dust method.

The K.-L. emulsions and spraying, C. P. CLOSE (*Delaware Sta. Bul. 73, pp. 20*).—The term "mixtures" for these insecticides is considered inappropriate and is abandoned in favor of "emulsions." K.-L. emulsions were used quite extensively during the past season with varying results, from success to a complete failure.

The author examined into the cause of these failures and believes that they were due largely to an incomplete preparation of the insecticide and careless spraying. It is recommended that the mixture should in all cases be made by violent churning and splashing by means of a hoe or dasher. The mixture can not be made in large lots by pumping or stirring. When not properly prepared, K.-L. emulsions are ineffective and to some extent dangerous. In some cases the grade of limoid used was not quite up to the standard. It is claimed that trees well sprayed during the previous fall remain quite free from San José scale during June and July, after which the insect begins to multiply. Two applications yearly are recommended for the K.-L. emulsions, viz, in October or November, and again in late spring. In order to increase the effectiveness of K.-L. emulsions tests were made of the combination of various substances.

A good combination was found by using sulphid of lime with the K.-L. emulsions. This gives a lime-sulphur combination with the addition of kerosene. The author reports good results from the use of K.-L. emulsions in strengths varying from 12½ to 30 per cent on peach, cherry, pear, and apple trees. Directions are also given for the combination of Bordeaux mixture with K.-L. emulsions, and also for the addition of Paris green to this mixture. It was found that K.-L. emulsion was a safe and effective insecticide for dipping nursery stock. For use in the spring the author recommends a 30 per cent strength on peach trees and 35 per cent solution on other trees.

Insects and insecticides (*Sacramento: State Hort. Com., 1905, pp. 23, figs. 22*).—The importance of careful and intelligent spraying is urged upon fruit growers. Some of the more important fruit pests are described and recommendations made regarding the best remedies for combating these insects. The more important pests mentioned in this pamphlet include San José scale, woolly aphis, prune aphis, black peach aphis, hop louse, canker worms, tussock moth, grasshoppers, peach-tree borer, peach moth, codling moth, etc.

Annual report of the royal sericultural station, Padua (*Ann. R. Staz. Bacol. Padova, 33 (1906), pp. 119*).—The work of the station, during the year 1905, is reviewed by the director, E. Verson (pp. 5-11).

In addition to a number of routine and practical matters the station studied the regeneration of the appendages of the silkworm larvæ, variations in the coloration of cocoons in Lepidoptera, disinfection with corrosive sublimate and other antiseptics in the case of flaccidity of silkworms, external markings indicating sex in silkworms, physiological coloration of cocoons, and other subjects. A study of the weight of silkworm cocoons as related to sex was carried on by E. Verson (pp. 19-25). This problem has been studied for a number of years at the sericultural station, and the conclusion is reached that the results thus far obtained indicate the impossibility of depending upon any external marks in silkworm cocoons for determining the sex.

E. Quajat reports on the prolonged estivation of silkworm eggs (pp. 26-65). These experiments were carried on with a number of races of silkworms, and in respect to the influence of heat the different races react quite differently. The green Japanese race was found to be less resistant than the yellow Japanese race or various hybrid races or the native yellow race. On the whole, it is concluded that a temperature of 15 to 17° C. is most suitable for the preservation of silkworm eggs in the summer. The same author presents an account of artificial parthenogenesis in silkworm eggs (pp. 77-92). In these experiments the author studied the influence of oxygen, high temperature, sulphuric acid, hydrochloric acid, carbonic acid, and electricity upon

silkworm eggs. E. Verson presents the results of a conference on a disease known as calcification of silkworms (pp. 66–76).

Notes are also given by E. Bisson on the influence of external conditions upon the physical properties of silk cocoons (pp. 93–101). As usual in the reports of the sericultural station, a bibliography is presented of literature relating to sericulture published during the year of the report.

FOODS—HUMAN NUTRITION.

The history of bread from prehistoric to modern times, J. Ashton (*London: The Religious Tract Society, 1904, pp. 185, pl. 1, figs. 30*).—It has been the purpose of the author to trace the history of bread making from prehistoric times to the present. Some of the subjects discussed are prehistoric bread, cereal grains in Egypt and Assyria, bread in Palestine and classic lands, eastern lands, Europe, and America, early English bread, milling, and bread making.

The varieties of bread (*Pure Products, 2 (1906), No. 1, pp. 13–20*).—A summary of data on the characteristics of graham bread, aerated bread, and other varieties.

Comparative values of different grades of wheat of crops of 1903 and 1904, R. Harcourt (*Jour. Amer. Chem. Soc., 28 (1906), No. 1, pp. 66–73*).—The analytical data reported, in the author's opinion, indicate "that the milling, chemical, and baking tests fail to bring out any very wide difference in the products of the individual lots of wheat studied. In yield of flour and in color of the bread the products of the lower grades are inferior, but in strength, as shown by the chemical analysis, and in yield of bread there appears to be little or no difference."

Estimating the fineness of flour, N. Wender (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 12, pp. 747–756*).—A summary of data regarding various methods of judging of the fineness and quality of flour led to the conclusion that no very satisfactory means of judging such factors are available.

The author reports a number of experiments in which wheat flour and rye flour of different degrees of fineness were treated with hydrogen peroxid. The amount of oxygen liberated in a given time increased with the degree of fineness. The determination of this factor, which he calls the oxygen value, is of great promise, though the method is not perfected.

The facing of rice, C. H. Cribb and P. A. E. Richards (*Analyst, 31 (1906), No. 359, pp. 40–45*).—The examination of a large number of samples of rice showed that the amount of ash in the polished samples, ranging from 0.52 to 2.22 per cent, was much greater than in the dull samples where it ranged from 0.29 to 0.57 per cent. The extra ash, it was found, could be removed by agitating the rice with water 2 or 3 times and apparently consisted of magnesia and silica. Talc, French chalk, or some similar substance was probably used in polishing rice and was responsible for its added mineral matter, though the authors point out that the exact method of polishing is a trade secret.

"The proportion of foreign matter present in some of the samples is quite sufficient to constitute a fraud, inappreciable, perhaps, by the individual purchaser, but ample to give to one unscrupulous vendor an unfair advantage over his more honest rivals. . . . As the alleged adulterant is more expensive than the rice itself, there could be no possible temptation to the manufacturer to adopt the process for the purpose of fraud, and in addition to this, it might also be urged that the foreign matter generally is, and always might be, largely removed during cooking. We understand this is the custom of native cooks in India, by whom the rice is always soaked and washed before use. Whatever may be the opinion in regard to the legal aspect of the question, it is somewhat startling to reflect that an article of diet of such common and widespread use, hitherto accepted as one of the purest forms of vegetable food, should so frequently contain a substance of a foreign nature."

Bananine (*Colonizer, 11 (1906), No. 121, p. 8, figs. 2*).—Data are given regarding the composition and characteristics of bananine, a flour prepared chiefly from Jamaica bananas. It is stated that palatable bread can be made from this product.

Floating manna grass (Glyceria fluitans), an almost forgotten native cereal, C. HARTWICH and G. HÅKANSON (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 8, pp. 473–478, fig. 1*).—The floating manna-grass seed, according to the authors' analysis, contains 13.54 per cent water, 9.69 per cent protein, 0.43 per cent fat, 75.06 per cent starch and sugar, 0.21 per cent crude fiber, and 0.61 per cent ash. This grain is sometimes used as food. [It is also found in the United States.]

The losses in weight when fish flesh is dried, F. PETERS (*Arch. Hyg., 54 (1905), No. 2, pp. 101–106*).—The losses which fish sustain when dried were studied, and found to vary considerably with different species and with different specimens of the same species, the average loss being 30.18 per cent, or, according to the author, less than the average values for different kinds of meat. The loss is chiefly due to water, though in some cases the dried material contained a little less ether extract than the fresh. The food value of dried fish as compared with dried meat is briefly discussed from the standpoint of ease of utilization.

The composition of unripe and canned peas, H. FRERICHS and G. RODENBERG (*Arch. Pharm., 243 (1905), No. 9, pp. 675–683*).—A number of samples of young and older green peas and canned green peas were analyzed, special attention being paid to the kind and amount of sugar present.

The proximate constituents of green peas did not vary much with the degree of ripeness. On the other hand, the age, irrespective of size, had a marked effect on the sugar content, the young peas containing from 16.05 to 28.37 per cent sugar, peas of medium size 10.33 to 17.60 per cent, and ripe peas 4.97 to 13.61 per cent. Similar differences were noted in the canned peas. As regards the character of the sugar present in young peas, tests showed that maltose, mannit, and inosit were absent and that the sugar present was cane sugar. The presence of added sugar in canned peas is spoken of.

Jams, marmalades, and jellies, A. MCGILL (*Lab. Inland Rev. Dept. [Canada] Bul. 104, pp. 19*).—Of 98 samples of jams, marmalades, and jellies collected in the Dominion of Canada, 66 per cent were found to contain glucose, 15 per cent preservatives, and 30 per cent dyes.

Olive oil, A. MCGILL (*Lab. Inland Rev. Dept. [Canada] Bul. 111, pp. 12*).—Of 108 samples of salad oils collected in the Dominion of Canada 66 were genuine olive oil, 2 were doubtful, 24 were cotton-seed oil sold as salad oil, and 16 were cotton-seed oil sold as olive oil.

"Certain highly refined grades of cotton-seed oil may be regarded as valuable foods, and as these take the place of olive oil in the making of salads it is perhaps not unnatural that they should be termed salad oils. It is, however, much to be regretted that such brands of cotton-seed oil are not sold under some characteristic name, such as cotton-seed salad oil, thus making their fraudulent sale impossible. When a salad oil is asked for the sale of cotton-seed oil properly refined can not be called adulteration, but when the article offered is plainly named as olive oil the substitution of cotton-seed oil in whole or in part is, of course, a case of adulteration."

A honey substitute, G. REISS (*Arb. K. Gsndhtsamt., 22 (1905), pp. 666–668*).—A honey substitute for which the name "Fruktin" was proposed was found to consist of cane sugar, with a small amount of tartaric acid and caramel.

New honey surrogates, A. BEYTHIEN (*Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 1–2, pp. 14–16*).—The composition of commercial honey surrogates is reported. One product consisted wholly or largely of cane sugar, and the other of cane sugar and starch sirup.

Highly colored confectionery, T. MACFARLANE (*Lab. Inland Rev. Dept.* [*Canada*] *Bul. 112, pp. 11*).—An examination was made of 111 samples of highly colored confectionery. One sample was found to contain arsenic, but the quantity was so very minute that it would be, in the author's opinion, completely harmless. None of the other samples contained lead or arsenic. The report furnishes data regarding the character of the coloring matters found and the cost of the confectionery.

Concerning spices. I, Pepper and cinnamon, H. LÜHRIG and R. THAMM (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11* (*1906*), *No. 3, pp. 129–134*).—Analyses of a large number of samples of pepper showed that with one exception the sand-free ash ranged from 4.67 to 5.28 per cent, and the alkali value of total ash from 9.7 to 11.3 per cent. The importance of these and other similar factors in determining the purity of pepper is discussed. In the case of cinnamon, the analytical data reported indicate that such factors are not equally satisfactory for judging of quality.

Ground pepper, A. McGILL (*Lab. Inland Rev. Dept.* [*Canada*] *Bul. 106, pp. 20*).—Of 290 samples of ground pepper examined 116 were found to be adulterated and 3 were doubtful. "The very high ash found for some samples of black pepper leads to the inference that the outer husks, separated in the preparation of the berries for grinding as white pepper, have been added to black pepper. It is difficult otherwise to account for such high ash as 10 to 15 per cent found in at least 12 samples analyzed."

Peppers, T. MACFARLANE (*Lab. Inland Rev. Dept.* [*Canada*] *Bul. 103, pp. 9*).—The data reported show that 47.7 per cent of the 86 samples of black and white pepper examined were adulterated and 40.7 per cent were genuine, while the remainder were doubtful.

Tincture of ginger, A. McGILL (*Lab. Inland Rev. Dept.* [*Canada*] *Bul. 110, pp. 14*).—In this investigation 108 samples of alcoholic preparations of ginger were examined, 70 per cent of these being so-called extract of ginger and the remainder ginger tinctures and essences. Of the samples of tincture of ginger 74.2 per cent were considered genuine.

Vinegar, A. McGILL (*Lab. Inland Rev. Dept.* [*Canada*] *Bul. 108, pp. 15*).—The mean acetic acid content of 242 samples of vinegar examined was 5.66 per cent, though the range was considerable. In the author's opinion, samples containing less than 3 per cent of acetic acid were objectionable as being too weak, while those that contained more than 8 per cent were fortified by the addition of acetic acid and therefore factitious. The question of possible metallic impurities was also studied and it was found that 12 of the samples examined contained traces of lead and 2 traces of zinc.

Cream of tartar, A. McGILL (*Lab. Inland Rev. Dept.* [*Canada*] *Bul. 109, pp. 14*).—The author reports data regarding the examination of 180 samples of cream of tartar. Of these 73 per cent were genuine, 19 per cent adulterated, and 8 per cent doubtful.

German food book (*Deutsches Nahrungsmittelbuch. Heidelberg: Carl Winter, 1905, pp. VIII+245, figs. 6*).—This volume, which was prepared by the German Association of Food Manufacturers and Dealers, contains explanatory definitions of the principal foods, condiments, and commercial products; a summary of German legislation of interest to manufacturers; and related data.

The value of fruit and vegetables in the diet, M. RUBNER (*Hyg. Rundschau, 15* (*1905*), *Nos. 16, pp. 817–828; 17, pp. 865–872*).—The author has summarized and discussed data regarding the composition and food value of fruits and vegetables, the importance of their ash constituents, the hygiene of handling and storing these food products, and related questions.

Distinctive features of animal and vegetable dietaries, L. B. MENDEL (*Amer. Med., 10* (*1905*), *No. 20, pp. 818–820*).—The comparative value of animal and vegetable diets is discussed on the basis of recent investigations in physiology and physiological chemistry.

The author points out that some of the more recent and popular vegetarian foods imitate meat foods quite closely in flavor and that this is a matter of importance from a physiological standpoint. "An instinctive craving for the normal stimulants to digestion is thereby satisfied. A bland diet is distinctly unphysiologic, and the explanation of this fact is no longer to be sought by empiric methods alone."

Many persons believe that a diet of vegetable foods with milk and eggs is especially valuable since it furnishes a minimum of purin bodies. The author considers it probable that the success attending the adoption of purin-free dietaries is attributable as much to the abstemiousness which they induce as to the absence of the so-called uric acid precursors and is of the opinion that no one would maintain that the actual nutrients of cereals, fruits, or nuts are of themselves more nutritious than those derived from animal sources.

"Vegetarianism undoubtedly has its place in ameliorating various functional disorders, without laying claim to any mysterious properties. . . . In the field of dietetic therapy, radical changes of diet frequently supply essential factors, or eliminate deleterious ones in most welcome and unsuspected ways. But the exclusive system has no adequate justification."

Climate and health in hot countries, G. M. GILES (*London: John Bale, Sons & Danielsson, Ltd., 1904, pt. 1, pp. XX+184, pls. 2, figs. 16*).—This is a popular treatise on personal hygiene in the hotter parts of the globe and related questions, useful information gained by personal experience being summarized. There are chapters on domestic architecture, clothing, water, food, insect pests as a means of transmitting disease, etc.

Great stress is laid upon the importance of a clean milk supply and the necessity of caring for cattle and handling milk in a sanitary way.

Boiling water for drinking, for culinary, and for toilet purposes is recommended as the most satisfactory way of preventing the transmission of disease by this channel. Thorough cooking of foods for purposes of sterilization is recommended, and the need of protection from flies and other insects and from dust is insisted upon.

The second part of the volume, which is devoted to tropical climatology, etc., is reviewed under another heading (p. 939).

The provisioning of the modern army in the field, H. G. SHARPE (*Kansas City, Mo.: Franklin Hudson Pub. Co., 1905, pp. 116, pls. 12*).—The organization and operation of the commissary department, transportation problems with reference to food supplies, utilization of local resources, and other questions concerning the provisioning of armies in active service are discussed, the author's object being to give an idea of the difficulties which attend the provisioning of troops in the field with the hope that measures may be devised for improvements. The volume contains a bibliography.

Field cookery, M. RINGELMANN (*Jour. Agr. Prat., n. ser., 10 (1905), No. 50, pp. 755–758, figs. 6*).—Different devices for use in field cookery are described with special reference to their use in providing food for large bodies of laborers, etc. Some data are also summarized regarding the efficiency of different kinds of fuel.

Self-cooker, G. H. MURPHY (*Mo. Consular and Trade Rpts. [U. S.], 1905, No. 302, pp. 242, 243*).—Data are quoted regarding the value of a self-cooker and the efforts which are being made in Germany to introduce such devices into workingmen's homes.

The digestibility of evaporated cream, T. MOJONNIER (*Med. News [Phila.], 87 (1905), pp. 877–884*).—When treated with artificial gastric juice the author found that protein of evaporated cream digested a little more rapidly than that of raw, pasteurized, or boiled milk. From digestion experiments with a child and a man it appeared that the child digested evaporated cream a little more thoroughly than the adult. Evaporated cream, the author concludes, like other forms of pure milk, is an

economical article of diet since its nutrients are practically all available for the needs of the body.

The influence of diet on growth and nutrition, C. Watson and A. Hunter (*Jour. Physiol., 33* (*1905*), *Nos. 4-5, Proc. Physiol. Soc., 1905, p. XIII; 34* (*1905*), *1-2, pp. 111-132, figs. 2, dgms. 16*).—The authors studied the influence of different diets on the growth and general nutrition of animals (rats). The diets comprised bread and skim milk, porridge made with skim milk, rice, raw horse meat, and raw beef.

In the author's opinion, a meat diet had an injurious effect, as was evident from the mortality in early life of the second generation of meat-fed subjects. "In the case of animals deprived of their ovaries the minimum amount of proteid requirement is less than in normal females. The permanent stunting of growth [was] associated with the use of a faulty diet in the growing period." Unfavorable results were obtained on the porridge diet with young subjects. Attention is directed to the similarity in chemical composition of the porridge and bread and milk diets.

Experiments on the protein and mineral metabolism in man, G. von Wendt (*Skand. Arch. Physiol., 17* (*1905*), *No. 3-5, pp. 211-289, figs. 4*).—In the experiments reported the metabolism of protein, sulphur, phosphorus, calcium, magnesium, potassium, sodium, chlorin, and iron was studied, and the influence of different sorts of food on the excretion of mineral constituents and other topics are discussed.

Some of the author's conclusions follow: Sulphur formed by the cleavage of protein is excreted more rapidly than nitrogen and therefore offers a better means of judging of the progress of protein cleavage. The calculated amount of phosphorus required daily per kilogram of body weight is about 0.01 gm., the calcium 0.008 gm., and the amount of magnesium 0.001 gm.

Replacing protein by gelatin in metabolism experiments, M. Kauffmann (*Arch. Physiol.* [*Pflüger*], *109* (*1905*), *No. 9-10, pp. 440-465*).—According to experiments made with a dog and with man, gelatin may replace protein in the diet if it is supplemented by suitable materials for building up the protein molecule. In a test of this character in which the author was the subject 93 per cent of the protein nitrogen was replaced by gelatin nitrogen, 4 per cent by tyrosin nitrogen, 2 per cent by cystin nitrogen, and 1 per cent by tryptophan nitrogen.

Experiments on the effect of tea upon stomach secretion, T. Sasaki (*Berlin. Klin. Wchnschr., 42* (*1905*), *No. 49, p. 1517; abs. in Zentbl. Physiol., 19* (*1905*), *No. 24, p. 919*).—It appeared from the experiments that tea hindered slightly the quantity of gastric juice and its acidity.

A new nitrogenous constituent of normal human urine, P. Hári (*Ztschr. Physiol. Chem., 46* (*1905*), *No. 1-2, pp. 1-8*).—The author has isolated a constituent (or rather its compounds) of urine, which he believes is different from urobilin, oxyprotein acid, and other known constituents.

Recent advances in physiology and biochemistry, edited by L. Hill (*New York: Longmans, Green, & Co.; London: Edward Arnold, 1906, pp. XII+740, figs. 33*).—This volume contains a number of papers by B. Moore, J. J. R. Macleod, L. Hill, M. S. Pembrey, and A. P. Beddard, summarizing the recent advance which has been made along a number of lines of research.

Such subjects are included as uric acid metabolism, hemolysins and immunity, the metabolism of fat and treatment of obesity, the influence of temperature and relative dryness of the atmosphere, of work, diet, baths, clothing, etc., on metabolism, the action of the digestive ferments, catalysts and chemical excitants, the colloidal structure of living matter and the influence of electrolytes in solution, the formation and absorption of lymph, the urinary excretion, etc. Each article contains a bibliography.

As the preface states, this book is designed "to set before the student of medicine the progress made in those branches of physiological study which have an immediate bearing on pathology and therapeutics, and to thereby give him an insight into the methods of research, and a training in the processes of deduction, which can not be gained from the bare and unstimulating outline of the text-book."

ANIMAL PRODUCTION.

The destruction of foods and feeding stuffs by micro-organisms. VI, The decomposition of vegetable feeding stuffs when air is excluded, J. König, A. Spieckermann, and H. Kuttenkeuler (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11* (*1906*), *No. 4, pp. 177-205*).—Bacteriological and chemical studies are reported in continuation of earlier work (E. S. R., 17, p. 687), as well as experiments in which goats and sheep were fed spoiled cotton-seed meal and cocoanut meal for a long time. In general, the health of the animals was not injured.

The spontaneous combustion of hay, F. W. J. Boekhout and J. J. O. de Vries (*Centbl. Bakt.* [*etc.*], *2. Abt., 15* (*1905*), *No. 17-18, pp. 568-573*).—Continuing earlier work (E. S. R., 16, p. 1004), from which the conclusion was drawn that the spontaneous combustion of hay was due to chemical processes and not to micro-organisms, the authors have studied the products formed when hay becomes heated with a view to learning which constitutents are directly concerned in the process. According to the results so far obtained it is nitrogen-free extract which undergoes decomposition, and the bodies which are responsible for this cleavage, that is, for the spontaneous combustion of hay, are neither soluble in water nor in 2 per cent sodium hydroxid solution.

Micro-photographs of the chaff of Gramineæ of importance in the examination of foods and feeding stuffs, H. Neubauer (*Landw. Jahrb., 34* (*1905*), *No. 6, pp. 973-984, pls. 5*).—The material described and illustrated is arranged with a view to facilitating inspection work.

Phosphate of lime in the feeding of farm animals, L. Grandeau (*Ann. Sci. Agron., 2. ser., 10* (*1905*), *II, No. 1, pp. 1-19*).—It is pointed out that phosphate of lime is an important addition to the ration of farm animals whenever the amount naturally supplied by feeding stuffs is insufficient, and investigations which have to do with this subject are summarized.

The energy value of red clover hay and corn meal, H. P. Armsby and J. A. Fries (*Landw. Jahrb., 34* (*1905*), *No. 6, pp. 861-923, pls. 2*).—An account of investigations noted from another publication (E. S. R., 17, p. 579).

Concerning the amount of saliva secreted and its relation to the physical characteristics of the feed, A. Scheunert and G. Illing (*Zentbl. Physiol., 19* (*1905*), *No. 23, pp. 853-856*).—The experiments reported were performed with 2 healthy horses. The esophagus had been operated upon in such a way that the food could be collected after it was swallowed.

It was found that 500 gm. of oats required for chewing and swallowing 960 gm. of saliva, and a like quantity of hay 2,500 gm.; a mixture of 300 gm. of oats and 100 gm. of chopped straw, 1,080 gm. of saliva; and 300 gm. of maize, 570 gm. of saliva. In earlier investigations it was found that 485 gm. of fresh grass required 335 gm. for insalivation. The recorded data show, in the authors' opinion, that physical characteristics (dryness and roughness) determine the amount of saliva secreted when food is chewed and swallowed, and that chemical composition does not influence it.

The adaptation of the salivary secretion to diet, C. H. Neilson and O. P. Terry (*Amer. Jour. Physiol., 15* (*1906*), *No. 4, pp. 406-411*).—In experiments with dogs it was found that the salivary glands and their secretions adapted themselves to the diet, sugar being found much more quickly in the case of bread-fed dogs than those fed meat.

"The saliva is more active than the gland extract, and the latter responds to the diet like the glands themselves. It is a well-known fact that extracts of glands in general are less active than the secretions. It may be that the gland contains a proferment. This may account for the latent period being longer in the gland extract than in the saliva itself, as the proferment must first be changed into the active

ferment. It is conceivable that this adaptation occurs in the human being if a proper diet is given—namely, that on a starchy diet the amylolytic power of the saliva is increased. This is being investigated, and the result will be reported later."

Studies on the digestion of herbivorous animals, P. BERGMAN (*Skand. Arch. Physiol., 18 (1906), No. 1-2, pp. 119-162*).—The literature of the subject is reviewed at length and experiments with intestinal ferments of Herbivora are reported, especially those of the cecum, as well as studies of the effects of ferments occurring in plants on natural and artificial digestion.

Rabbits were used for the natural digestion experiments. In some of the tests the hay or straw used was cooked to destroy the enzyms normally present. Such treatment diminished the digestibility of protein and nitrogen-free extract, but increased the digestibility of pentosans and crude fiber.

According to the author, proteolytic and sugar-forming enzyms are present in uncooked hay and straw, which are very powerful. The diminished digestibility of protein of heated hay was attributed in part to the effect of heat on the protein and in part to the destruction of the proteolytic enzyms. The diminished digestibility of the nitrogen-free extract was attributed to the destruction of cytases. That amylolytic enzyms were not responsible is shown by the fact that in all the experiments starch was thoroughly digested.

The digestive processes in horses when maize is fed, A. SCHEUNERT and W. GRIMMER (*Ztschr. Physiol. Chem., 47 (1906), No. 1, pp. 88-125*).—At the end of a fasting period horses were fed a ration of 1,500 gm. maize and killed at periods varying from 30 minutes to 9 hours after the food was taken, the work as a whole being similar to earlier investigations by H. Goldschmidt [a], in which horses were fed oats.

From a study of the stomach and intestines and their contents deductions were drawn regarding the digestibility of maize, some of which follow: The movement of food through the digestive tract varied greatly with different animals. The stomach contents, aside from the portion near the fundus membrane, had at first an alkaline reaction but soon became acid. Whatever the reaction, lactic acid fermentation could be detected in the intestines, as well as gaseous fermentations, some of the gases produced being inflammable.

Considering the digestion and resorption of carbohydrates in the stomach and intestines as a whole it appeared that in the first 2 hours 20 to 30 per cent of the amount consumed was digested and about 20 per cent resorbed. In the eighth to the ninth hour about 50 per cent was digested and r sorbed. The digestion of maize protein in the stomach is very rapid and at first proceeds much like that of oat protein, though later it surpasses it. After 5 or 6 hours about 50 per cent of the protein of both oats and corn in the stomach was digested. The rate of digestion in the stomach and intestines and other questions are considered.

The rational feeding of farm animals by syndicates, KOHLER (*L'amélioration rationnelle du bétail, par les syndicats d'elevage. Paris: Librairie Agricole de la Maison Rustique, 1906, pp. 146; noted in Bul. Soc. Nat. Agr. France, 66 (1906), No. 1, p. 119*).—A general treatise on cattle feeding on a large scale.

Production and feeding of cattle, horses, asses, and mules, P. DIFFLOTH (*Production et alimentation du bétail, cheval, ane, mulet. Paris: J. B. Baillière & Sons, 1904, pp. XVI + 504, figs. 140*).—This volume, which is one of the series entitled Encyclopédie Agricole, is a general treatise on the breeding, feeding, care, and management of cattle, horses, asses, and mules.

Sheep, goats, and pigs, P. DIFFLOTH (*Mouton, chèvre, porc. Paris: J. B. Baillière & Sons, 1905, pp. VIII + 418, figs. 90*).—The general characteristics of sheep, goats, and pigs, breeds, feeding, care, management, and related questions are taken up in this volume, which is one of the series entitled Encyclopédie Agricole.

[a] Ztschr. Physiol. Chem., 10 (1886), p. 361; 11 (1887), p. 286.

Cattle feeding experiment, W. Bruce (*Edinb. and East of Scot. Col. Agr. Bul. 8, pp. 35-47*).—Using 3 lots of 8 2-year-old Irish cattle, the relative merits of decorticated, Egyptian, and Bombay cotton-seed cake were studied. In the 20 weeks covered by the test the average daily gain per head on the decorticated cotton-seed cake ration was 1.93 lbs., and on both the Egyptian and the Bombay cake rations 2.07 lbs.

According to the author, "Bombay cotton-cake has turned out more effective per unit than Egyptian cotton-cake. . . . Bombay cotton-cake has been found a cheap, safe, and suitable food for starting the winter feeding of 2-year-old bullocks which are receiving a liberal ration of turnips. About 6 lbs. per head per day, however, is probably about the maximum quantity it is advisable to use. When the feed of concentrated food rises above this quantity the Bombay cotton-cake should be supplemented by a food containing more oil, e. g., linseed cake."

Feeding broken or crushed bones to cattle, D. Hutcheon (*Agr. Jour. Cape Good Hope, 28 (1906), No. 2, pp. 210-212*).—It is a common practice with many farmers in South Africa to give their cattle broken bones (which are readily eaten) to supply the body with phosphates.

Experiments were undertaken to learn the comparative digestibility of small pieces of bone and bone meal. Two lbs. of roughly crushed bone 0.17 to 0.5 in. in size were introduced into the stomach of a fasting ox through an opening in the rumen. These bones were excreted apparently unchanged by the action of the digestive juices. When crushed dried bone about the size of coarse oatmeal was fed to a steer at the rate of a pound a day for 7 days it was apparently completely digested, none of the bone being found in the excreta. The bone and the oats which were fed at the same time were dyed with methylene blue. Many of the oats were recovered in the feces still colored.

Measure of the mechanical work performed by Limousin cattle, Ringelmann (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 16, pp. 628-631*).—According to the measurements reported, a pair of Limousin cattle 4½ years old, weighing 1,380 kg. with the yolk, furnished mechanical work equivalent to 190 kilogram meters of available work per second, from which the conclusion is drawn that this race of cattle makes excellent draft animals.

Tests of the strength of oxen, M. Ringelmann (*Bul. Soc. Nat. Agr. France, 65 (1905), No. 8; abs. in Rev. Gén. Agron., 15 (1906), No. 1, pp. 29-32*).—The method rests on the assumption that the "mean sustained effort which can be furnished in steady work" is a constant proportion of the maximum effort that the animal can put forth. A similar definite relation is assumed between the maximum speed without a load and the mean sustained speed when doing work. These relations have been experimentally shown to be approximately 25 per cent and 30 per cent, respectively—that is to say, the actual rate of work is represented by $.25 \times .30 = .075$ of the product of maximum pull and maximum speed. When both of these elements are considered it may happen that owing to favorable build an animal showing rather light draft exhibits greater power than a heavier and slower animal.

Twenty-nine yoke of oxen were tested, the strongest pair developing a mean rate of work of 190 kilogram meters per second, or 2.5 horsepower. It is found necessary to have the oxen driven by a familiar hand, as they do not do their best for strangers. A special harness was used which reduces the maximum pressure on the animal, as otherwise the effort put forth would be limited at the point where the pressure becomes painful.

Theoretical and practical calf feeding, M. Rasquin (*L'alimentation théorique et pratique du veau. Renaix, Belgium: J. Leherte-Courtin, 1905, pp. 93, figs. 2*).—The general functions of nutrition are discussed and information summarized on the value of a large number of materials as supplements to skim milk in calf feeding, including among others meat meal, potato starch, flaxseed (alone and with corn meal and with

different kinds of starch), bread, ground grain, eggs, meat powder, calf feeds, sugar, dried blood, and hay tea.

Much of the work summarized was carried on under the author's supervision. The different feeding stuffs are not compared, but the investigations as a whole warrant the deduction that milk fat may be profitably replaced by other feeding stuffs in calf feeding. One of the topics discussed at some length is the importance of phosphate of lime (ground bone) in the rations of young animals.

Steam-cooked milk for calves, Bugge (*Ztschr. Fleisch u. Milchhyg., 16 (1906), No. 7, pp. 228–230*).—In connection with a consideration of the feeding of sterilized milk to calves to prevent the spread of tuberculosis, tests were reported of the amount of water which the passage of the steam through it added to the milk in a given time. It required 50 minutes to raise the temperature of 150 liters of milk from 10 to 85° C. The increase in volume was in round numbers 23 liters.

Pig feeding experiments with dried sugar-beet chips and dried potato pulp, Klein (*Milchw. Zentbl., 1 (1905), No. 12, pp. 529–537*).—The feeding experiments reported showed, in the author's opinion, that as good results were obtained when dried potato pulp was added to a barley and skim milk ration as when barley and skim milk were fed alone. Less satisfactory results were obtained with the dried sugar-beet chips. An examination of the fat of the pigs showed no marked differences which could be attributed to the different feeding stuffs tested.

Twenty years' experiments on the feeding of work horses, L. Grandeau and A. Alekan (*Ann. Sci. Agron., 2. ser., 10 (1905), II, Nos. 1, pp. 138–160; 2, pp. 161–225, figs. 4*).—The investigations which the authors have carried on for 20 years with work horses are summarized and a number of deductions drawn regarding the variation in price of feeding stuffs, digestibility, and food value of different rations, the economy of substituting various feeding stuffs and mixtures for oats, and related questions. The investigations referred to have been noted (E. S. R., 16, p. 587)

Barley for horses, P. Van Biervliet (*Rev. Gén. Agron., 14 (1905), No. 10–11, pp. 458–461*).—A summary of data showing the decided value of barley for horses.

Poultry raising, C. Voitellier (*Aviculture. Paris: J. B. Baillière & Sons, 1905, pp. XII + 484, figs. 158*).—A general treatise on poultry raising in which the principal characteristics of various breeds of chickens, ducks, geese, turkeys, guinea hens, and pigeons are described, and questions of feeding, breeding, housing, and management are discussed.

Poultry houses and fixtures (*Quincy, Ill.: Rel. Poultry Jour. Pub. Co., 1906, 6. ed., pp. 95, figs. 174*).—A number of papers by different authors are including in this publication, which takes up the construction of poultry houses, sheds, fixtures, coops, yards, and similar questions.

Races of domestic poultry, E. Brown (*London: Edward Arnold, 1906, pp. XII + 234, pl. 1, figs. 89*).—In this discussion of the races of domestic poultry of different countries, it has been the author's intention to consider the qualities which bear upon profitable poultry raising rather than external characteristics. The attempt has been made to trace the origin, history, and distribution of domestic poultry and to show the evolution of breeds and their classification. Special attention is paid to judging poultry and to the relation between external characteristics and internal qualities with reference to poultry breeding.

Poultry division, D. D. Hyde (*New Zeal. Dept. Agr. Ann. Rpt., 13 (1905), pp. 133–151, figs. 9*).—Statistics of the egg trade and poultry industry are given, as well as descriptions of egg cases and trap nests. The work of the poultry-breeding stations and other topics connected with the work of the poultry division are also briefly spoken of.

The year's work in poultry, D. F. Laurie (*Jour. Dept. Agr. So. Aust., 9 (1906), No. 6, pp. 391–396*).—Data are given regarding commercial poultry breeding, laying competitions, poultry societies, diseases and pests, and related questions. In the

author's opinion the last year has been a very successful one for the local poultry industry.

How frequently does the setting hen turn her eggs? H. F. Prince (*Cornell Countryman, 3 (1906), No. 6, p. 139, fig. 1*).—From observations made with a number of hens it was found that in every instance the eggs were moved every day and did not remain in the same part of the nest for more than 3 days. "The thorough manner in which the hen turns the eggs may well furnish us a clue to the most natural and proper treatment of the eggs when under the artificial conditions of the incubator."

DAIRY FARMING—DAIRYING.

Dairy investigations in the northeast of England, D. A. Gilchrist and C. B. Jones (*Trans. Highland and Agr. Soc. Scot., 5. ser., 18 (1906), pp. 63-74*).—Studies of variations in the composition of milk and their probable causes have been in progress for a number of years, some of the results of which having already been reported (E. S. R., 15, p. 906).

The experiments in 1904-5 showed that when cows were milked at 6 a. m. and 6 p. m., the morning milk contained on an average 4 per cent of fat and the evening milk 3.6 per cent, but when the cows were milked at 6 a. m. and 4 p. m., the percentages were respectively 3.6 and 4.3. The average daily yield of milk was somewhat greater when the intervals between milkings were equal. Some creaming tests are also reported.

Milk investigations at Garforth, 1905, C. Crowther (*Trans. Highland and Agr. Soc. Scot., 5. ser., 18 (1906), pp. 110-142*).—Feeding grain to cows on pasture was studied experimentally with 2 lots of 5 animals each, in periods lasting from July 18 to October 9. Commencing with a daily ration of 2 lbs. of undecorticated cottonseed cake and 2 lbs. of decorticated cake, the amount of the latter was increased to 4 lbs. and later to 6 lbs. Under the conditions of the experiment the smaller ration proved insufficient for maximum production and the most liberal feeding was far from economical.

Milk records, J. Speir (*Trans. Highland and Agr. Soc. Scot., 5. ser., 18 (1906), pp. 237-280*).—Tests were made of 815 cows belonging to 30 herds. Two milk-record societies were represented. The tests of 18 herds were made every 21 days during 1 year and of the remaining herds every 14 days for 34 weeks.

Calculated to a basis of milk containing 3 per cent of fat, the average production of cows tested for the entire year was 875 gal. The average production of 10 per cent of the best cows of these herds was 1,170 gal. of 3 per cent milk, and of 10 per cent of the poorest cows, 677 gal. Ten per cent of the best cows in the remaining herds produced, on an average in 34 weeks, 826 gal. of 3 per cent milk, and 10 per cent of the poorest cows, 526 gal. Tables are also given showing the milk production according to the age of the cows.

Influence of asparagin on milk production, T. Pfeiffer (*Abs. in Centbl. Agr. Chem., 35 (1906), No. 1, pp. 48-51*).—In experiments with goats, the substitution of asparagin for a part of the proteids in the ration produced a marked decrease in the fat content of the milk without materially lowering the yield, and was unfavorable to the growth of the animals.

Feeding dairy cows, C. D. Smith (*Michigan Sta. Bul. 234, pp. 85-109*).—This is essentially an abridged form of Bulletin 149 of the station (E. S. R., 9, p. 1081).

Is the passage of food fat into milk demonstrable by the Winternitz method of feeding iodized fat? S. Gogitidse (*Ztschr. Biol., 47 (1906), No. 4, pp. 475-486*).—This is a critical review of the literature of this subject with a bibliography. The method, as brought forth by K. Winternitz, consists in feeding the animal iodized fat and examining the milk for the presence of iodin. The author's

opinion is unfavorable to this method as a means of demonstrating the direct transformation of food fat into milk fat.

On the Baudouin reaction in human milk fat, ENGEL (*Ztschr. Angew. Chem., 19 (1906), No. 7, pp. 283-286*).—A positive Baudouin reaction was regularly obtained 1 to 1½ hours after feeding sesame oil. This period was followed by a second period, in which the reaction was negative, and this by a third period, in which a positive reaction was again obtained. When the feeding of sesame oil was continued for 7 days the reaction was positive for all three periods.

Purity of Raleigh's milk supply, F. L. STEVENS (*Raleigh, N. C.: Bd. Aldermen, May, 1905, pp. 7*).—Forty samples of milk collected in Raleigh, N. C., from February 4 to April 29 were examined, the results showing no sample containing less than 34,000 bacteria per cubic centimeter. Only 9 samples contained less than 100,000 and 17 contained more than 1,000,000. The fat content in no instance fell below 3 per cent. The relation of dirt in milk to bacterial content is illustrated by the following figures: Milk containing 5.2 mg. of dirt per liter showed the presence of 3,338,775 bacteria per cubic centimeter; milk containing 20.7 mg., 7,079,829 bacteria, and milk containing 36.8 mg., 12,897,600 bacteria.

Milk treated with hydrogen peroxid, P. ADAM (*Rec. Méd. Vét., 83 (1906), No. 6, pp. 169-173*).—The author endeavored to determine whether milk free from hydrogen peroxid was previously treated with this substance. Storch's reagent consisting of paraphenylenediamin, and Schardinger's reagent consisting of methylene blue and an aldehyde were tested for this purpose.

The following conclusions were reached: Raw fresh milk not previously treated with hydrogen peroxid is colored red by the addition of guaiac and hydrogen peroxid, and blue by paraphenylenediamin. The methylene blue is decolorized by the presence of an aldehyde. The same milk, when spoiled, no longer gives the first two reactions but still decolorizes Schardinger's reagent. Raw milk containing hydrogen peroxid gives the color reaction with guaiac alone or with paraphenylenediamin alone and does not change the color of Schardinger's reagent. Raw milk previously treated with hydrogen peroxid but no longer containing this substance gives, upon again adding hydrogen peroxid, the same reactions as pure milk with guaiac and paraphenylenediamin, but unless putrefied does not decolorize methylene blue. Boiled milk shows none of the preceding reactions.

Action of formalin and hydrogen peroxid on milk, P. BANDINI (*Riv. Ig. e Sanit. Pub. [Rome], 16 (1906), p. 23; abs. in Biochem. Centbl., 5 (1906), No. 3, p. 144*).—According to the author, formalin interferes with the action of rennet on milk, the change produced being increased by the length of time formalin acts and by the amount added. On the contrary, milk treated with hydrogen peroxid shows a normal reaction with rennet.

Neither formalin nor hydrogen peroxid exerts a marked influence on the soluble ferments in milk. Formalin, even in small quantities, interferes with the proteolytic ferments such as pepsin and pancreatin and in large quantities affects to a marked extent the chemical and physical properties of the precipitated casein. Hydrogen peroxid does not have this effect. The addition of formalin in the proportion of 1:5,000 to 1:10,000 preserved milk from 6 to 12 days. The addition of hydrogen peroxid in the proportion of 1:100 to 3:100 preserved milk from 1 to 6 days.

Methods of preserving milk, P. VIETH (*Fühling's Landw. Ztg., 55 (1906), No. 4, pp. 113-120*).—The author discusses the importance of preventing contamination as a means of improving the keeping qualities of milk and the preservation of milk by means of cold, pasteurization and sterilization, chemical preservatives, and other means.

On the preservation of milk with hydrogen peroxid, EICHHOLZ (*Milchw. Zentbl., 1 (1905), No. 11, pp. 500, 501*).—This is a criticism of the work of Baumann previously noted (E. S. R., 17, p. 74).

Preservation of milk before skimming, L. MARCAS and C. HUYGE (*Bul. Agr. [Brussels], 21 (1905), No. 6, pp. 1111-1115*).—Practical methods of straining, cooling, etc., are mentioned and their value illustrated by experimental data.

Action of the ultra-violet rays on milk, N. GERBER and A. HIRSCHI (*Rev. Gén. Lait, 5 (1906), No. 11, pp. 252, 253.; Milchw. Zentbl., 2 (1906), No. 3, pp. 119, 120*).—Attempts to sterilize milk by means of the ultra-violet rays were unsuccessful. The authors, however, considered it possible, by more intense rays than those used and longer exposure, to sterilize milk in this way, although the method would not apparently be capable of practical application.

The significance of streptococci in milk, P. G. HEINEMANN (*Jour. Infect. Diseases, 3 (1906), No. 2, pp. 173-182, pls. 3*).—This is the full report of investigations of which an abstract has already been noted (E. S. R., 17, p. 800). The three plates show the growth of *Streptococcus pyogenes* and *S. lacticus* from two sources on serum broth, lactose broth, and litmus milk.

Streptococci and leucocytes in milk, W. G. SAVAGE (*Jour. Hyg. [Cambridge], 6 (1906), No. 2, pp. 123-138*).—The methods employed are described. In the counting of leucocytes the author makes use of the Thoma-Zeiss blood-counting apparatus in much the same manner as previously described by Doane (E. S. R., 17, p. 181). One cc. of milk is diluted with about 20 cc. of Toisson's fluid and centrifuged for 10 minutes at 1,800 revolutions per minute. The cream is then broken up with a glass rod and the mixture is again centrifuged for a second period of 10 minutes after which the fluid is aspirated off to the 1 cc. mark. After thoroughly mixing the remaining 1 cc. a sufficient quantity is placed in the Thoma-Zeiss apparatus and the preparation examined in the same way as in the enumeration of blood corpuscles.

When the counting is done by fields, the author estimates the number of leucocytes per cu. mm. of milk by the formula $\frac{56,000\ y}{11d^2}$, in which y equals the average number of leucocytes per field, and d the number of squares of the blood counter which just spans the diameter of the field. The methods of counting leucocytes in dried and stained preparations used by Stokes and others were found very unsatisfactory.

Samples of milk from individual cows and also of mixed milk were examined. The results showed that streptococci were very frequently present. In the milk of individual cows streptococci were present in 42.5 per cent of the samples when 1 cc. of milk was used in the examination, and invariably present in the mixed milk. In all they were present in 45 out of 68 samples examined, or 66 per cent. As all of the cows were apparently healthy, the results are considered as showing clearly that streptococci as a class are very prevalent in pure milk. The study of the streptococci isolated showed 12 types, the characters of which are given.

Leucocytes were present in every sample, ranging in numbers from 35 to 4,380 per cu. mm. in samples from individual cows and from 21 to 1,980 in mixed milk. Contrary to conclusions reached by Bergey (E. S. R., 16, p. 699), the author's results show no connection between the numbers of pus cells and streptococci. The author states that he can not differentiate between a leucocyte and a pus cell, and that he is not prepared at present to lay down an arbitrary standard as to what number of leucocytes in milk per cu. mm. is to be designated pus.

Bacillus coli, considered as a definite indicator of contamination, was found in 17.5 per cent of the samples of milk from individual cows, in 36 per cent of the samples of mixed milk examined within 3 hours from the time of milking, and in 94 per cent of mixed and market samples not examined promptly.

The leucocyte test of milk, R. TROMMSDORFF (*München. Med. Wchnschr., 53 (1906), No. 12, pp. 541-543*).—In estimating the leucocyte content, 5 cc. of milk was centrifuged and the sediment measured in a graduated sedimentation tube.

In the majority of cases the leucocyte content determined in this way varied from mere traces to 0.4 cc. per liter. In some instances, however, the sediment amounted

to 2.5 per cent or more. Physical examinations of the udder and the leucocyte test were made with a large number of cows, the results being considered very favorable to the latter method. The author considers the leucocyte test practical and suggests as a result of his investigations that mixed milk containing more than one volume per million of sediment should be considered as indicating mastitis, and that a higher leucocyte content than 2 volumes per million should be considered as establishing with certainty the presence of disease in the udder. The streptococci which were always present in large numbers when the leucocyte content was high were found, in many cases, to be pathogenic to mice. The prevention of the sale of such milk is, therefore, considered very desirable.

The milk of cows affected with mastitis was found to possess an unusually high bactericidal power which was considered as probably related to the high leucocyte content. The more detailed results of these investigations which were conducted in conjunction with Dr. Rullmann will be published later.

The Tromsdorff leucocyte test for milk, W. RULLMANN (*Milch Ztg., 35 (1906), No. 14, pp. 157, 158*).—Attention is called to this test which consists in centrifuging a small quantity of milk and determining the amount of the sediment. The results so far obtained are considered very favorable to the method.

Sodium chlorid in milk, C. PORCHER (*Rev. Gén. Lait, 5 (1906), Nos. 8, pp. 173-178; 9, pp. 193-198*).—The author concludes, from the results of his studies, that sodium chlorid is one of the most variable elements in milk, and that its presence in greater or less amounts does not depend directly upon food, but upon purely physical processes—the regulation of the osmotic equilibrium. He would, therefore, separate sodium chlorid from the other mineral constituents of milk, the presence of which is probably more or less directly related to the chemical function of the glandular tissue. It is noted that a maximum of sugar in milk is associated with a minimum of salts, especially sodium chlorid and vice versa.

Comparative study of milk tests, C. HUYGE (*Bul. Agr. [Brussels], 21 (1905), No. 6, pp. 1096-1110*).—Of six methods of determining fat the Gerber method was given the preference as the result of a number of comparative tests. Considerable attention was paid to the estimation of cream separated spontaneously or by means of the centrifuge. While the results are not strictly accurate, the creamometer is considered very valuable for farm tests.

Contribution to the knowledge of the distribution of lactic ferments outside the milk, C. BARTHEL (*Rev. Gén. Lait, 5 (1906), Nos. 10, pp. 223-233; 11, pp. 246-251; 12, pp. 265-272*).—The literature of this subject is briefly reviewed and extended observations are reported.

According to the author's results, *Bacterium lactis acidi* is found on all species of plants growing on cultivated lands. On the contrary, it is not found on plants distant from cultivated fields, or, if found, is in a very weakened condition. The same statement applies to the presence of this organism in the soil. *B. coli commune* and *B. lactis aerogenes*, especially the first, are found on all living plants whether coming from cultivated fields or from the forest. They are also found everywhere in the soil. *B. lactis acidi* is found, naturally, everywhere in the stable, in the air, in the water, and different feeding stuffs, and in the manure. It is thus very natural that the milk becomes infected as soon as it is drawn. The most rigorous precautions are, therefore, necessary in order to lessen the amount of contamination during milking.

A municipal milk service for London, L. PARKES (*Pub. Health [London], 18 (1906), No. 7, pp. 439-441*).—After raising objections to present systems of municipal milk depots, such as the want of effective supervision over the production of the milk, the necessity of pasteurization and sterilization when the milk reaches the city, and the added cost making the business unprofitable, the author makes suggestions concerning a municipal milk service for London.

Cleansing of milk vessels: Relative value of washing powders, A. H. STEWART (*Amer. Med., 11 (1906), No. 7, pp. 241-244*).—An investigation was made of the methods employed in cleansing bottles and cans used for milk.

Several methods were found in use, (1) rinsing out cans or bottles with cold water, which, while almost necessary to remove the remaining milk, is considered as leaving the can almost as dirty as before; (2) washing bottles and cans with a hand brush and a solution of one of the various washing powders, the method most often used by the small dealer, which was frequently found to be done carelessly and without hot water, or a washing-powder solution strong enough to be satisfactory; (3) washing with machines with a revolving brush and solution of washing powder and rinsing in water, the results of which method were considered unsatisfactory from a bacteriological standpoint; (4) throwing a jet of live steam into inverted cans, which method frequently serves to fix the dirt already in the can and does not destroy the bacteria; (5) washing by means of large machines constructed to throw powerful streams of hot washing-powder solutions into the bottles, and followed by boiling water, which method, the author says, was investigated thoroughly and found most satisfactory; and (6) washing with soap and water and sterilizing in a steam box or autoclave, which is a fairly good method, but applicable only when a comparatively small number of bottles are to be cleaned daily.

The fifth method mentioned is considered capable of cleansing 95 per cent of the bottles perfectly. The author states that 500 bottles have been watched going through this kind of machine without finding one that had not been thoroughly cleansed. "This is probably the only rapid practical method of sterilizing and cleansing milk vessels."

Several washing powders were compared as regards their ability to destroy bacteria and cleanse milk vessels. The germ-destroying power was found to be slight. Sodium carbonate and powders containing a large proportion of this material were found to cleanse most thoroughly and most rapidly. Powders composed of alkali and a fat cleansed well, but less rapidly.

The author considers the establishment at each milk-receiving depot in Philadelphia of a can washing and cleansing building, where all cans must be sterilized before being sent back to the farms, as the only remedy for the deplorable condition existing in that city. The advantages of such a scheme are enumerated.

The examination of pasteurized milk, P. BUTTENBERG (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 7, pp. 377-385, fig. 1*).—Tests were made of the following methods used for detecting pasteurized milk: (1) The guaiac reaction, (2) Schardinger's reaction with methylene blue and formaldehyde, (3) the reaction of Neisser and Wechsberg depending upon the reduction of methylene blue by bacteria, (4) the bacterial content, and (5) the incubation of the sample according to the method of Bonnema (E. S. R., 16, p. 1123). The data obtained in the application of these methods to samples pasteurized by the author and to commercial samples are reported in tabular form. The different methods may be readily employed under practical conditions and, when taken together, furnish much more reliable data for judging a sample than the results obtained by any one method alone.

The pasteurization of cream and the use of pure cultures in butter making, J. ARTHAUD-BERTHET, A. PERRIER, and L. DUPONT (*Rev. Gén. Lait, 5 (1906), Nos. 10, pp. 217-222; 11, pp. 241-246*).—The results of a study of butter making in the region of Isigny, France, are reported along with experiments in which pasteurization and pure cultures were employed with satisfactory results. The authors recommend pasteurization at 65° C. for 5 minutes and the use of suitable cultures.

Protest against slandering American butter, G. L. MCKAY (*Hoard's Dairyman, 37 (1906), No. 12, p. 336*).—The author contends that only a very small amount of American butter contains an abnormally high percentage of water.

Red-spotted butter, H. STADLINGER and J. PODA (*Milchw. Zentbl., 2 (1906), No. 3, pp. 97–115*).—The morphological and cultural characters of an organism isolated from red butter and designated *Bacterium butyri rubri* are reported. The organism is considered as belonging to the *Bacillus prodigiosus* group, though distinct from that species. The pigment produced by the organism was identified as prodigiosin. The most probable source of infection was through water.

On the importance of strictly anaerobic putrefactive bacteria in cheese ripening, A. RODELLA (*Centbl. Bakt.* [*etc.*], *2. Abt., 16 (1906), No. 1–3, pp. 52–56, pls. 2*).—In continuation of previous investigations (E. S. R., 16, p. 196) the author reports cultural and biochemical studies of putrefactive anaerobes capable of producing in milk cultures, caproic, valeric, and butyric acids from casein. Anaerobic propionic acid ferments will be considered in the next communication, and the importance of putrefactive bacteria in cheese making in a later article, while a more detailed discussion in the form of a monograph on putrefaction is announced.

The influence of the fat content of milk on Emmenthal cheese, O. JENSEN (*Rev. Gén. Lait, 5 (1906), No. 12, pp. 272–277*).—As a result of experiments in making Emmenthal cheese with milk containing different percentages of fat, the author concludes that when properly made the quality of Emmenthal cheese is improved with an increase in the fat content of the milk up to at least 4 per cent, and that this is due not only to the increase of the most valuable constituent in the cheese, but because the increased amount of fat favors the ripening of the cheese.

The influence of cooking on Emmenthal cheese, O. JENSEN (*Rev. Gén. Lait, 5 (1906), No. 13, pp. 299–303; Landw. Jahrb. Schweiz, 20 (1906), No. 2, pp. 154–156*).—Temperatures varying from 48 to 60° with corresponding periods of stirring decreasing from 120 to 25 minutes were studied in the manufacture of Emmenthal cheese.

The results indicate that great care should be taken to avoid using too low a temperature, for a limit is soon reached when the action of heat can not be equalized by a longer period of stirring. A lower temperature than 55° was not found satisfactory. Analyses of the cheese at the age of 4 months are reported. The use of cultures of *Bacterium acidi propionici* gave marked results at all temperatures employed, even at 60°.

Roquefort cheese, E. MARRE (*Le Roquefort. Rodez: Carrère, 1905; rev. in Rev. Gén. Lait, 5 (1906), No. 11, p. 260*).—This monograph deals with the production of milk by sheep, manufacture of Roquefort cheese, and commerce in this cheese.

VETERINARY MEDICINE.

Comparative anatomy of the domesticated animals, A. CHAUVEAU, trans. by G. FLEMING (*New York: D. Appleton & Co., 1905, enl. ed., pp. XXXVI + 1084, figs. 585*).—This edition is a revision and enlargement by S. Arloing of the author's original text-book, translated and edited, with notes by the translator. The material in the volume is arranged according to the usual scheme of descriptive anatomy and constitutes a valuable guide to the study of comparative anatomy in our farm animals.

Comparative pathology of the blood, P. MEIER (*Ztschr. Tiermed., 10 (1906), No. 1–2, pp. 1–81, pl. 1*).—The cell content of normal blood in various animals, particularly in the horse, is discussed in considerable detail for the purpose of securing data upon which to base conclusions obtained from the study of the leucocytes and red blood corpuscles in cases of disease.

The author compared the conditions found in man and animals in various diseases, including contagious coryza, croup, angina, pleuro-pneumonia, tetanus, malignant edema, ringworm, hydremia, etc. In general the morphological relations in regard to the leucocytes agree closely in man and animals. This agreement is especially close between man and the horse, and it is, therefore, believed possible to apply conclusions derived from a study of horse blood to similar conditions in man. There

appears to be an antagonism between the neutrophilous and eosinophilous cells, so that a rapid multiplication of the former reduces the number of the latter. The results obtained in a study of pernicious anemia, contagious coryza, angina, and various animal diseases are discussed in detail in connection with a bibliography of the subject.

Tumors and tumor-like lesions in the esophagus and surrounding tissue, A. W. Mörkeberg (*Maanedskr. Dyrlæger, 17 (1905), No. 7–8, pp. 209–241, pls. 2, fig. 1*).—In a classification of tumors found in the region of the esophagus in cattle the vast majority are actinomycomata. Fibromata, melanomata, and tuberculous lesions occur less frequently. Detailed notes are given on the anatomy of these tumors, their location, and the means of making a differential diagnosis.

The animal parasites of man, M. Braun, trans. by Pauline Falcke (*London: John Bale, Sons & Danielsson, Ltd., 1906, 3. ed., pp. XIX + 453, figs. 290*).—The original revised text has been considerably enlarged, corrected, and edited by L. W. Sambon and F. V. Theobald. As brought up to date in its present form, it includes an account of the life history, anatomical features, and parasitic habits of all animal parasites known to infest man. These parasites are arranged according to their usual zoological position under the heads protozoa, flat worms, nematodes, acanthocephala, leeches, and arthropods. Naturally the greater number of species of parasites infesting man belong to the last-named group.

Micro-organisms with spiral bodies, R. Blanchard (*Rev. Vét. [Toulouse], 31 (1906), No. 2, pp. 86–97*).—A description is presented of various spiral micro-organisms, including species of Spirosoma, Vibrio, Spirobacillus, Spirillum, Treponema, and Trypanosoma. The more important species of these genera are mentioned with reference to their economic importance.

The control of contagious diseases of animals, L. Hubert (*Rev. Vét. [Toulouse], 31 (1906), No. 2, pp. 104–110*).—Statistics are given on the occurrence of anthrax, foot-and-mouth disease, rabies, contagious pleuro-pneumonia, tuberculosis, and glanders. It is believed that pleuro-pneumonia will soon be eradicated by the continuation of stringent measures such as the slaughter of all affected animals and disinfection of premises. Notes are given on indemnities paid for tuberculous animals. The number of cases of glanders in France is diminishing.

Report of the State veterinarian, L. Pearson (*Ann. Rpt. Penn. Dept. Agr., 10 (1904), pp. 69–96, figs. 12*).—Brief reference is made to the work of the veterinarian in combating rabies, treating cattle affected with tuberculosis, and in the control of glanders, blackleg, anthrax, infectious abortion, hemorrhagic septicemia, calf cholera, horse mange, hog cholera, and Texas fever.

The effect of vaccination upon cattle infected with tuberculosis is discussed by the author and S. H. Gilliland (pp. 85–96). This treatment consisted in frequent inoculation with living cultures of tubercle bacilli of low virulence. A number of calves were given subcutaneous injections of tuberculin at intervals of 2 to 10 days. The treatment with tubercle bacilli of low virulence had a distinctive curative effect and in all treated animals the lesions were encapsulated, but still contained tubercle bacilli. Apparently under such treatment tuberculous lesions do not extend but may recede and finally become absorbed.

Report of the chief of the cattle bureau, A. Peters (*Agr. of Mass., 1904, pp. 251–324*).—A financial statement is presented regarding the work of the office, and tables are given showing in detail the inspection service for live stock throughout the State. As in previous years the greatest expense of the cattle bureau has been incurred in paying indemnities for cattle slaughtered for tuberculosis. Notes are also given on the prevalence of tuberculosis, glanders, *Strongylus paradoxus* and trichina in hogs, rabies, sheep scab, actinomycosis, blackleg, Texas fever, hemorrhagic septicemia, takosis, and contagious ophthalmia.

Report on the Austrian Veterinary Service for 1901 (*Bericht über das Österreichische Veterinärwesen für das Jahr 1901. Vienna: Alfred Hölder, 1905, pp. 284, pls. 14*).—A detailed account is given of the present condition of domestic animals in Austria and of the prevalence of various diseases among them, particular attention being devoted to foot-and-mouth disease, anthrax, blackleg, glanders, sheep pox, rabies, mange, hog cholera, swine erysipelas, and other infectious diseases. Statistics are presented on the losses due to such diseases, the cost of controlling them, and on veterinary education.

Poisoning of horses, cattle, and pigs with beans containing prussic acid, C. Dammann and M. Behrens (*Deut. Tierärztl. Wchnschr., 14 (1906), Nos. 1, pp. 1–4; 2, pp. 13–16*).—According to the authors' observations considerable numbers of horses, cattle, and hogs have died suddenly as a result of eating beans which in most cases came from foreign countries.

In the observations first made along this line the species was not determined. Prussic acid was found in the beans, however, by means of the usual tests for this substance, and feeding experiments showed the presence of the poison in the beans. Later a sample of beans used for feed was sent to the Berlin Botanical Garden for identification, and it was found that the sample contained *Phaseolus lunatus*, *P. vulgaris*, *Cajanus indicus*, and a species of Dolichos All of these species of beans appeared to contain prussic acid in some quantity.

Castration of females of animals other than the horse, W. Robertson (*Agr. Jour. Cape Good Hope, 28 (1906), No. 1, pp. 90–95, figs. 5*).—Notes are given on successful methods of caponizing and spaying pigs and other animals.

Experiments in serum therapy in cases of pasteurellosis of laboratory animals, J. Bridré et al. (*Compt. Rend. Soc. Biol. [Paris], 60 (1906), No. 2, pp. 62, 63*).—In the author's experiments it was found that rabbits could be gradually immunized by means of injections of organisms causing pleurisy and other forms of pasteurellosis. Rabbits treated in this way were not only immune to septicemia and various other laboratory diseases, but furnished a serum which protected other rabbits when inoculated in doses of 2 to 4 cc.

In the investigation of animal diseases it is quite necessary that laboratory animals be protected in order to save the time which would be lost by the sudden outbreak of infectious diseases among them. For this purpose sheep were used to furnish serum for the vaccination of laboratory animals. The normal serum of sheep was found not to possess any preventive property, but after repeated inoculation with gradually increasing doses the serum was quite effective.

Comparative study of human and animal tuberculosis, H. Kossel (*Ztschr. Tuberkulose, 8 (1906), No. 2, pp. 101–119*).—In the author's experiments, which are described in detail in this article, 27 cultures of bovine tubercle bacilli were used, and these cultures, after subcutaneous inoculation, produced a generalized tuberculosis in 32 out of 33 cattle, while similar inoculation with human tubercle bacilli caused only local lesions. The author believes, however, that man is susceptible to the bacilli which cause pearl disease in cattle. Attention is called to the biological differences which appear in the human and bovine tubercle bacilli and notes are given on the views expressed by Ravenel, Arloing, Lignières, and others in discussing the article.

Tuberculosis, W. P. McCray (*Ann. Rpt. Penn. Dept. Agr., 10 (1904), pp. 692–698*).—The symptoms and pathology of tuberculosis are described with particular reference to the work which the live stock sanitary board of Pennsylvania has done in examining cattle for tuberculosis. This board has examined and tested with tuberculin 44,801 cattle and of this number 5,869 have been condemned, destroyed, and paid for.

The histology and pathogenesis of uterine and ovarian tuberculosis in cattle, H. Fischer (*Ztschr. Tiermed., 10 (1906), No. 1–2, pp. 82–109, pls. 4*).—A

critical review of the literature of this subject is given together with details secured by the examination of 50 cases in cattle.

In this study it was found necessary to separate the cases into two classes according as the uterus or ovary was more extensively affected. In 21 cases it was found that the ovary was first attacked and that infection spread to the uterus. In 29 cases the disease appeared in a more advanced stage in the uterus and the infection was probably primary in this organ. The author believes, however, that in a majority of cases infection spreads from the oviduct to the uterus. The infection of these organs may take place as a result of contagion of tuberculosis from the outside.

Tuberculous nature of diffuse enteritis in cattle, LIENAUX and VAN DEN EECKHAUT (*Ann. Méd. Vét., 55* (*1906*), *No. 2, pp. 84–93*).—In many cases the authors have observed the coexistence of ordinary tuberculosis and enteritis. A study was made of this matter for the purpose of determining whether the enteritis observed in such cases was of tuberculous origin. In this study small experimental animals were used, as well as cattle, for inoculation purposes. It was found that the bacteria obtained from such cases of enteritis were identical with the tubercle bacillus.

Three years' experience in protective vaccination of cattle against tuberculosis by von Behring's method, STRELINGER (*Ztschr. Tiermed., 10* (*1906*), *No. 1–2, pp. 118–132*).—Attention is called to the fact that other investigators have furnished convincing experimental proof of the importance and effectiveness of von Behring's method of vaccination. The author describes in some detail experiments along this line.

The method appears to be absolutely harmless to cattle when attention is given to the most obvious requirements of the technique of the operation. In 62 cases the method was applied to calves which were already tuberculous, and among this number 49 animals appeared to be completely cured by the treatment. The tuberculin test was given to 590 cattle which had been previously vaccinated and kept under observation for a year or more. Of this number only 9 animals or 1.5 per cent reacted to tuberculin. This percentage is quite satisfactory when it is remembered that in similar herds untreated about 50 per cent reacted to tuberculin.

Vaccination against tuberculosis, DEGIVE ET AL. (*Ann. Méd. Vét., 55* (*1906*), *No. 2, pp. 76–84*).—This is the report of the commissioner appointed to make a test of the vaccination method proposed by von Behring for the control of tuberculosis. The animals, after vaccination, were tested by means of subcutaneous and intravenous inoculations as well as by feeding virus and exposure by proximity to infected animals. As a result of this test it is concluded that the vaccination recommended by von Behring does not cause tuberculosis in any case and produces a great natural resisting power toward ordinary contamination. Vaccinated animals can not be infected with tuberculosis even by the use of large doses of virulent material. In carrying out this method of vaccination on a practical scale, it is desirable to keep vaccinated animals from undue exposure to tuberculosis during the first few months after vaccination. It is also recommended that vaccination be not undertaken in stables where broncho-pneumonia prevails at the time.

The sugar-producing action of the tubercle bacillus, C. FERMI (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig., 40* (*1905*), *No. 2, pp. 187, 188*).—The author tested the reducing power of tubercle bacillus by cultivating it in a potato medium which had previously been shown to contain no reducing reagent. In all cases positive results were obtained or, in other words, the tubercle bacillus was found to possess a reducing power.

The species of actinomyces, E. HAASS (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig., 40* (*1905*), *No. 2, pp. 180–186*).—Specimens of actinomyces from various sources were examined with particular reference to the determination of the relationship between these forms. As a result of the author's investigations it is proposed that the group of

actinomyces be placed between Bacteria and Hyphomycetes with four genera—Corynebacterium, Actinobacterium, Mycobacterium, and Actinomyces.

The diagnosis of anthrax by means of cultures, FISCHOEDER (*Fortschr. Vet. Hyg., 3 (1906), No. 10, pp. 217–225, pls. 4*).—According to the author's experiments, which substantiated in some respects previous experiments by other investigators, it appears that under favorable conditions anthrax colonies do not develop in a form sufficiently characteristic to enable their differentiation from colonies of other micro-organisms. In fact a number of other organisms appear to develop at times in colonies almost identical in appearance with those of anthrax.

The morphological characteristics of anthrax colonies are not specific enough to allow a diagnosis to be made upon that basis alone in practice. It is often necessary, therefore, to resort to inoculation to determine the pathogenic action of suspected material in order to reach a well-founded diagnosis.

The resistance of granulations to anthrax, R. GIANI (*Centbl. Bakt. [etc.], 1. Abt., Orig., 40 (1905), No. 2, pp. 238–241*).—The author found that cultures of anthrax when rubbed on granulating wounds were quite effectively checked in their penetration into the underlying tissues. In a few instances, however, the anthrax bacillus actually penetrated through the granulating tissue.

The properties of the antianthrax serum of Sclavo, E. CLER (*Centbl. Bakt. [etc.], 1. Abt., Orig., 40 (1905), No. 2, pp. 241–247, pl. 1*).—It was found that anthrax bacilli obtained from blood are so affected by the antianthrax serum of Sclavo that they possessed the property of fixing alexins. The author gave particular attention to a study of the relation between white blood corpuscles and the anthrax serum.

Cultural characters of the blackleg bacillus, T. SMITH (*Ztschr. Infectionskrank. u. Hyg. Haustiere, 1 (1905), No. 1, pp. 26–31*).—The author calls attention to the fact that in his experiments the blackleg bacillus in peptone bouillon without meat, sugar, or any particles of animal organs, sets free from 50 to 100 per cent of the gas from dextrose and lactose but none or very little from saccharose. The composition of this gas was approximately 2 parts hydrogen for 1 of carbon dioxid. Milk coagulated within a few days.

Report on the preparation of rinderpest protective serum, A. LINGARD (*Calcutta: Supt. Govt. Printing, India, 1905, pp. 116*).—Various methods have been used in protecting cattle against rinderpest, and among the schemes of vaccination the author describes those in which use is made of bile, serum and virus, serum alone, defibrinated blood, normal bile, vegetable seeds, extracts from testes, and other reagents. The methods have also been classified as slow or rapid according as the process is hastened or not.

Of the various methods used at Muktesar on plains' cattle, the best and most economical results were obtained by using the rapid process which consists in injecting 6,000 cc. of virulent rinderpest blood. The animal is bled 15 days after the subsidence of the inoculation fever and after 78 days is again inoculated and bled. When large doses of virulent rinderpest blood are injected into plains' cattle, a weak or attenuated serum is obtained which sometimes possesses the highest protective power at the first bleeding. The protective value of a serum was found to depend considerably on the degree of severity of the initial attack of rinderpest. Apparently there is no constant relation between the protective value of a serum and its specific gravity or the total amount of proteids which it contains. Notes are also given on rinderpest in camels and methods of controlling it.

Specific papular stomatitis of cattle, a disease resembling aphtha, R. OSTERTAG and BUGGE (*Ztschr. Infectionskrank. u. Hyg. Haustiere, 1 (1905), No. 1, pp. 3–20, pl. 1*).—A disease appeared among cattle in Friedrichsfelde during which symptoms developed which closely resembled those of foot-and-mouth disease. The body temperature, however, was only 39° C. No salivation was observed either during or after eating.

A number of sharply defined papules were observed on the hard gums and mucous membrane of the cheeks. These areas were somewhat larger than lentils. In some cases similar areas were observed on the underside of the tongue 1 to 1½ cm. in diameter. When material was taken from such areas and used in the inoculation of calves, a reddening and swelling at the point of inoculation were observed within 2 to 4 days and papules appeared after 13 days. The disease is therefore infectious. In further experiments it was found that the defibrinated blood is virulent but not the blood serum. By placing healthy animals in contact with diseased ones it was found that the disease is transmitted spontaneously. Apparently the micro-organism is filterable and ultramicroscopic.

The disease in question can not be identical with sporadic aphtha or foot-and-mouth disease since no vesicles appear at any time and the disease is confined entirely to the mouth cavity. The skin and hoofs appear never to be affected.

Abortion in cattle, W. Robertson (*Agr. Jour. Cape Good Hope, 27 (1905), No. 5, pp. 624–628*).—The causes of noncontagious and contagious abortion are briefly outlined and notes are given on the treatment of the latter form of the disease. In this disease the only effective treatment is preventive and aims at the eradication of the organism which causes the disease. The fetus and fetal membranes should be burned and all parts of the cow liable to contamination should be treated with a solution of corrosive sublimate or some other antiseptic.

Report of the Swiss Veterinary Society on granular contagious vaginitis, E. Hess (*Landw. Jahrb. Schweiz, 19 (1905), No. 6, pp. 338–445*).—A special commission was organized among the Swiss veterinarians to make a study of contagious vaginitis of cattle in all its relations.

This committee undertook the collection of statistics which indicate the distribution of the disease in Switzerland, the percentage of cattle affected, the seriousness of symptoms, the means of dissemination of the disease, and its treatment. In some localities from 40 to 60 per cent of cattle were affected. Antiseptic treatment in the way of general washes is recommended by nearly all of the veterinarians on the committee as the most successful means of controlling this disease. Among the remedies thus applied mention should be made of carbolic acid, creolin, lysol, ichthyol, boric acid, silver nitrate, bichlorid of mercury, copper sulphate, acetate of lead, Bacillol, etc.

The periodical disinfection of the premises where the disease has occurred or may be expected to occur is recommended as an effective measure in preventing the spread of the plague. It is recommended that contagious vaginitis be included among the diseases of which notification must be given and that infected animals should not be used for breeding purposes.

A bacilliform piroplasmosis of cattle, and an intestinal coccidiosis in Tunis, E. Ducloux (*Bul. Dir. Agr. et Com. [Tunis], 9 (1905), No. 97, pp. 573–578*).—A bacillar parasite was observed among cattle in a large number of cases of piroplasmosis in certain localities in Tunis. Autopsies made on a number of cases showed that certain parasitic worms, especially *Strongylus contortus* and *Bunostomum phlebotomum*, were present. The action of the parasitic worms appeared to cause hemorrhagic injuries in the intestinal walls, and the author suggests that their presence may render infection with piroplasmosis more easy and more frequent than it otherwise would be.

The study of the causes of intestinal coccidiosis in Tunis showed that in the intestines there were numerous lesions containing masses of fibrin, coagulated blood, and a species of Coccidium in enormous numbers. This organism is described, and notes are given on its different developmental forms.

Experiments with Jensen's polyvalent serum for infectious diarrhea of calves, J. Jansson (*Svensk Vet. Tidskr., 10 (1905), No. 12, pp. 486, 487*).—Jensen's

serum was used in attempting to prevent the development of calf diarrhea in 21 cases, with good success in all except four of the calves. In the 4 cases which were without result the vaccination was not given until 2 or 3 days after birth. It is recommended that in order to prevent the disease with certainty the serum should be injected immediately after the birth of the calf or at least as soon as possible.

Further experiments in the disinfection of cattle cars with aqueous solutions of formaldehyde, J. SCHNÜRER (*Ztschr. Infectionskrank. u. Hyg. Haustiere, 1 (1905), No. 1, pp. 32–44*).—It was found in these experiments that a 1 per cent solution of the gas in the air within the car was sufficient for disinfection. In order to obtain this, 2½ liters of commercial formalin were dissolved in 100 liters of water, and of this mixture 60 liters were used for each car, the cars being previously cleaned as thoroughly as possible by mechanical means.

Diseases of lambs, T. W. CAVE (*Natal Agr. Jour. and Min. Rec., 8 (1905), No. 12, pp. 1236–1246*).—Particular attention is given in this article to a discussion of the infestation of lambs with tapeworms, lungworms, the parasite of gid, and stomach-worms.

Sheep pox on the Schönau estate near Leipsic, NOACK (*Deut. Tierärztl. Wchnschr., 14 (1906), No. 3, pp. 25, 26*).—Notes are given on an outbreak of sheep pox which showed symptoms of unusual virulence. In a herd of 630 sheep 190, or 30 per cent, died. In nonfatal cases recovery took place after 3 to 5 weeks. Nearly all of the animals were affected.

Experimental myasis in goats, with a study of the life cycle of the fly used in the experiment, and a list of some similar noxious Diptera, F. C. WELLMAN (*Jour. Med. Research, 14 (1906), No. 2, pp. 439–446*).—A species of fly closely resembling *Sarcophaga regularis* was captured in some numbers and allowed to attack a goat kept confined for purposes of observation. The fly is vivaporous and deposited a large number of larvæ in the nasal passages of the goat, causing a serious illness. The life history of this species is worked out and notes are given on various other species of Oestridæ, Sarcophagidæ, Muscidæ, and Anthomyidæ.

The control of swine plague, FOTH (*Berlin. Tierärztl. Wchnschr., 1906, No. 4, pp. 57, 58*).—On account of the wide distribution of swine plague in Germany it is necessary to take strict measures for its control. The official diagnosis of swine plague is based largely on the clinical demonstration of the infectiousness of the disease. This diagnosis is to be supported by the post-mortem findings, and in doubtful cases by bacteriological cultures. The veterinary police are largely concerned in determining the character of the outbreak and in separating the acute and chronic cases, since these two classes require different treatment. In chronic cases of swine plague no restriction is necessary, provided the animals are to be slaughtered, while all traffic in such animals for breeding purposes should be prohibited.

Health factors in horse management, S. S. CAMERON (*Jour. Dept. Agr. Victoria, 3 (1905), No. 10, pp. 725–732*).—Attention is called to the various evidences of the beginning of disease which may appear in horses. Among the predisposing causes mention is made of overstocking, unsuitable food and water, environment, and hereditary tendencies. In the prevention of the disease it is obvious that particular attention should be given to these points.

Loss of horses in Kansas, F. S. SCHOENLEBER (*Industrialist, 32 (1906), No. 17, pp. 263, 264*).—Horses are occasionally killed by eating corn or corn fodder affected with molds, particularly *Aspergillus glaucus*, which often follows the attacks of the bollworm in corn. The treatment of this trouble is unsatisfactory, but some benefit may be derived from the administration of purgatives and iodid of potash in 1 dram doses.

Pathogenesis and transmissibility of latent glanders, A. BONOME (*Patogenesi e Trasmissibilità della Morva Chiusa. Padua: Ist. Anat. Patol. R. Univ. Padova, 1905, pp. 115*).—The present report contains an account of what were probably the

most extensive experiments ever carried out in feeding glanders bacilli to horses and experimental animals to determine the method and extent of infection through the alimentary tract.

The author fed the bacilli in capsules sealed so that the glanders bacilli could not escape until the capsule was digested in the stomach. It was found possible to produce latent glanders in horses as a result of this method of infection. The disease, however, was not very virulent and sometimes persisted for a year or even 13 months without giving any evidence of its existence. Such animals did not give a mallein reaction or show any increased agglutinating power of the blood toward glanders bacilli. Care was exercised in all cases that the capsules were not broken in passing through the esophagus. It was found in experiments with guinea pigs and other animals that the digestive juice exercises a considerable effect upon the glanders bacillus, hindering its development and reducing its virulence.

One of the reasons why glanders produced through the agency of the alimentary tract may require a long time to become established is found in the fact that the glanders bacilli are so greatly diluted with large quantities of food material, water, and digestive juices in the alimentary tract. Nevertheless, infection does take place from bacilli in the alimentary tract causing primitive foci of infection in the mesenteric glands. The specific localization of glanders bacilli in the lungs in such cases is a secondary process. During the author's experiments it was shown that glanders bacilli are eliminated in the urine of infected animals.

Etiology of pneumonia in horses, LORENZ (*Berlin. Tierarztl. Wchnschr., 1906, No. 5, pp. 73–75*).—An outbreak of this disease gave the author an opportunity to study its symptoms and also to carry on some investigations regarding its etiology. A micro-organism was found in the form of a bacillus with thickened ends, and this bacillus occurs under other developmental forms, including diplococci and streptococci. These organisms were not to be seen except by the use of the most approved microscopic apparatus. The author believes that the organism may safely be considered as the cause of pneumonia.

Observations on the blood of horses infected with tetanus, M. E. TABUSSO (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig., 40 (1906), No. 3, pp. 311–317*).—In this study particular attention was given to the hemolytic and agglutinative power of the blood of horses infected with tetanus. It was found that a temperature of 55° C. destroyed the hemolytic power of the serum.

Treatment of tetanus in race horses, CHAPARD (*Bul. Soc. Cent. Méd. Vét., 83 (1906), No. 2, pp. 64–70*).—It has frequently been observed that in thoroughbred horses of nervous temperament tetanus is usually fatal. The author finds, however, that under certain circumstances this peculiar susceptibility to tetanus may be of value in treating the disease, for, in some instances, the first symptoms appear so promptly that the disease is detected in time to prevent its further development by antiseptic treatment of the wound where infection took place. In one case treatment of this sort combined with the use of antitetanic serum, chloral, and caffein brought about a complete recovery within 10 days.

Nodules in the mucous membrane of the stomach in horses, A. TOMIOLO (*Gior. R. Soc. ed. Accad. Vet. Ital., 55 (1906), No. 1, pp. 5–7*).—In an inspection of horse meat in an Italian abattoir the author reports the finding of nodules in the gastric mucous membrane of an otherwise healthy horse. These nodules contained a worm identified as *Filaria spiroptera*.

Spirillosis in the horse in French Guinea, G. MARTIN (*Compt. Rend. Soc. Biol.* [*Paris*], *60 (1906), No. 3, pp. 124–126, fig. 1*).—Symptoms closely resembling those of trypanosomiasis were observed in a horse in the blood of which numerous spirilla were found associated with the red blood corpuscles. When this blood was used for the inoculation of chickens no results were observed, but in sheep a fever developed within 37 days and trypanosomes appeared in the blood.

Cilia and transverse divisions in the spirillum of fowls, A. Borrel (*Compt. Rend. Soc. Biol.* [*Paris*], *60* (*1906*), *No. 3, pp. 138-141, figs. 2*).—In order to stain the cilia of this organism it was found necessary to make use of Löffler's method. Notes are given on the appearance of the cilia and on divisions which occur in the spirilla, which are well illustrated.

Preventive vaccination against distemper of dogs, Meis (*Berlin. Tierärztl. Wchnschr., 1906, No. 3, p. 44*).—In the author's experience with Piorkowski's serum in the treatment of dog distemper no beneficial results were obtained, and cases are cited in which other investigators have likewise had negative results.

Piorkowski's serum for dog distemper, Lange (*Berlin. Tierärztl. Wchnschr., 1906, No. 4, pp. 59-61*).—The author tested the value of this serum in the treatment of 8 cases of dog distemper. While the results obtained are not a sufficient basis for general conclusions the author believes that if administered in the early stages of the disease the serum gives favorable results. In chronic cases, especially such as show nervous symptoms and heart weakness, the serum was of distinct benefit. The author recommends the use of at least 10 cc. as a dose.

Is rabies infectious during the incubation stage? W. Koppitz (*Berlin. Tierärztl. Wchnschr., 1906, No. 2, pp. 19, 20*).—Data are presented regarding rabies in animals and man, from which it appears that the disease is infectious even in the incubation stage. It is therefore recommended that legal regulations should include the destruction of dogs and cats which have come in contact with rabid animals immediately, before the symptoms of the disease appeared in the latter.

Transmission of rabies through superficial wounds and the value of local treatment, V. Galtier (*Jour. Méd. Vét. et Zootech., 57* (*1906*), *pp. 19-21*).—Some doubt is occasionally entertained regarding the depth of the wound necessary for producing infection from rabies. The author finds that infection may take place through the most superficial injuries of the skin.

Rabies in rats, with observations on this disease in various species of mice, B. Galli-Valerio (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig., 40* (*1905*), *No. 2, pp. 197-204; 40* (*1906*), *No. 3, pp. 318-331, figs. 2*).—The possibility of rats and mice acting as agents in the distribution of rabies has frequently been suggested by different investigators.

The author tested this matter in a number of species, including *Mus rattus, M. decumanus, M. musculus,* and *M. sylvaticus.* Detailed notes are given on the inoculation tests made by the author and the subsequent progress of the disease. As a result of these experiments it is concluded that a number of rodents may be concerned in the transmission of rabies and that the virulence of the virus may be somewhat increased by these animals. The bite of small rodents may therefore become very dangerous. *Mus rattus* was found to be well adapted as a laboratory animal for the rapid preparation of virulent rabies virus.

The relation between fowl plague and rabies, W. Rosenthal (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig., 40* (*1905*), *No. 2, pp. 204-206*).—In the author's study of this disease it was found that subdural inoculation of fowls with the virus of fowl plague produced death within a short time with violent symptoms resembling rabies. It is believed that some relationship exists between rabies and fowl plague.

Prosthogonimus cuneatus in hens' eggs, K. Wolffhügel (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 1* (*1905*), *No. 1, pp. 21-25*).—In the white of the hens' egg 4 specimens were found of a trematode worm belonging to the species *Prosthogonimus cuneatus.* They were below the average in size, perhaps on account of the unusual situation for these parasites. In the same egg a small amount of food material was found which had become inclosed within the egg shell during the formation of the egg. Attention was called to the possibility of such parasites gaining entrance to hens' eggs during their formation.

RURAL ENGINEERING.

Irrigation on the farm, A. S. Kenyon (*Jour. Dept. Agr. Victoria, 3 (1905), No. 10, pp. 681-692, pls. 2, figs. 3*).—A description of local methods of irrigation at Doncaster, a fruit-growing district 10 miles from Melbourne.

The water for irrigation in this district is usually stored in small reservoirs built across gullies or on hillsides by the farmers. The author describes methods and details of construction. He advises "fallowing, with subsoil stirring, and frequent harrowing of the surface to conserve and carry forward much water from one season to the next;" but shows that "each farmer can carry out for himself works providing some small amount of irrigation, utilizing for that purpose water which otherwise would have been mainly dissipated in the air without going into the ground for use by the plants."

The duty of water varies from 2 in. for some kinds of trees to 36 in. for perennial fodder crops such as alfalfa. Good drainage is found to be essential on irrigated lands. The annual rainfall is about 26 in.

The irrigation of La Campine, T. Lebens (*Separate from Ann. Trav. Pub. Belg., 1897, No. 5, pp. 55, figs. 16*).—This report, written by the engineer in charge, describes the territory concerned, the former efforts to reclaim it and provide canals for transportation, the present system, and methods of applying water.

The entire area involved is about 5,000 acres. The writer points out the difficulty of using the same canal for both transportation and irrigation, and concludes: "Where continual navigation must be provided for it will always be wise to avoid a canal serving the double purpose of navigation and irrigation. It is hard to reconcile the requirements of industry and of farming." The report includes a technical discussion of water measurements, and four folding plates are given showing modules, distributing systems, and a map of the canals.

Notes on irrigation in South Africa, C. D. H. Braine (*Transvaal Agr. Jour., 4 (1905), No. 13, pp. 8-21*).—A paper read before a scientific society in Johannesburg for the purpose of encouraging the practice of irrigation in South Africa. The author discusses the duty of water and the problem of alkali or "brak" soils, drawing largely on American and other sources in the absence of local data.

By comparison with similar conditions a duty of 285 acres per cubic foot per second is estimated. The interesting local contribution is a table of land values for dry and irrigated lands in the Cape Colony. Dry land runs from 4s. to £12, averaging roughly £3 10s.; while irrigated land is quoted as high as £250, a rough average of the quotations being £38 per acre. The author concludes that £20 per acre may be safely invested in irrigation works, but urges that only the most promising schemes should as yet be attempted, leaving the larger projects to develop later after more experience has been gained.

The work of the hydrographic branch of the Geological Survey (*U. S. Geol. Survey Ann. Rpt., 26 (1904-5), pp. 160-224, pl. 1, fig. 1*).—A brief statement of the fields covered and of the work undertaken in all parts of the United States.

The work of the Reclamation Service of the Geological Survey (*U. S. Geol. Survey Ann. Rpt., 26 (1904-5), pp. 249-299*).—A summary of the projects undertaken under the Reclamation Act, giving the location, approximate area of land, and approximate cost of each.

Contributions to the study of drainage, E. Risler and G. Wery (*Ann. Inst. Nat. Agron., 2. ser., 4 (1905), No. 1, pp. 23, dgms. 4*).—The measurements reported in this article were made in the years 1867-1876 on a plat of ground carefully selected for "rigorously normal conditions." They show the relations between rainfall, drainage, evaporation, and temperature of the air. A table covering the years from 1873 to 1876 is given showing the daily rainfall and runoff of the drains.

"The quantity of water discharged by the drains is lowest during the active period of vegetation from April to September," due apparently to the transpiration by plants, and does not closely follow increased rainfall. The average monthly discharges for ten years are platted with the rainfall, temperature, and evaporation, showing that the drainage increases as temperature and evaporation decrease, the maxima occurring in December and March. But annual means of these quantities platted for a 10-year period show similar curves throughout.

The work rests on the supposition of an impervious subsoil, evaporation being taken as the difference between rainfall and the combined loss by drainage and transpiration, the latter being obtained by weighing the dry matter produced and multiplying by empirical constants as determined by M. Risler.

Sedimentation: Its relation to drainage, J. W. Dappert (*Engin. News, 55 (1906), No. 5, pp. 125, 126*).—An abstract of a paper presented before the Illinois Society of Engineers and Surveyors in January, 1906.

From his experience with over a hundred drainage districts the author has found that open drains are invariably subject to filling up with sediment, from the wash of high-land streams, or from the sloughing and caving of banks, regardless of the grades employed. He recommends as preventives that ditches be dug wider and deeper than required, to allow for sloughing of the slopes; that tile-drains should be given several feet outfall into the ditch; that curves be avoided, and waste banks be put well back from the edge of the ditch; that concrete walls be used at tile outlets and where surface water enters, and that willows and other water-loving trees should be cut out. Regular inspection and repairs are indispensable.

In conclusion he adds: "With all these things done, and even well done, the open ditches will yet require frequent recleaning, but their period of efficiency can be greatly extended by their proper care and management. Lastly, I reiterate, do not build an open ditch where a tile-drain, pipe, or conduit can possibly be employed."

Proceedings of the Second Annual Iowa State Drainage Convention (*Ames: Iowa Drainage Assoc., 1905, pp. 65, figs. 7*).—This report includes a paper by C. G. Elliott on drainage assessments, damages, and taxes, and the relation of drainage projects to roads and railroads; an address by R. M. Wright on the new Iowa drainage law, with particular reference to the constitutionality of the exercise of eminent domain by drainage systems; a paper by A. Marston on road drainage, describing the work of the State highway commission; an address by D. A. Kent on tile drainage, especially for corn lands; an article by L. E. Ashbaugh on the reclamation of meandered lake beds by drainage; and a paper on the relation of soil to underdrainage, by W. H. Stevenson.

Third report on the highways of Maryland, A. N. Johnson (*Md. Geol. Survey [Rpt.], 5 (1905), pp. 145–218, pls. 4, figs. 4*).—This report includes a progress report of work done by the counties under the direction of the State geological survey, cost data for road building in different localities, an account of laboratory tests of road materials, and a set of standard specifications for earth, macadam, and telford roads.

A new method for tensile tests of cement is used, in which the cement is molded in the form of a ring, which is broken by hydraulic pressure applied by expanding a rubber tube inside the ring, in a machine of special design. An outline of a suggested county-road law is given, providing for three elected county road commissioners and a county road engineer with a permanent staff of supervisors.

Building the new barn, A. P. Ketchen (*Rpt. Farmers' Insts. Ontario, 10 (1904), pt. 1, pp. 82–95, figs. 8*).—The author considers in a popular manner the approved methods of building foundations, basement walls, doors, windows, and floors for a large barn. The question of ventilation is fully discussed.

Machinery in agriculture, Stange (*Vrtljschr. Bayer. Landw. Rat., 10 (1905), No. 4, pp. 599–603*).—A review of a work by Dr. Alex. Lang (Berlin: Geo. Siemens, 1904).

Statistics showing the distribution of machinery of various kinds among farms of different sizes are given, indicating that few farms under 12 acres use farm machinery (power machines, seeders, manure spreaders, and mowers), and less than half of those from 12 to 50 acres. Dr. Lang has prepared cost data showing the actual saving in manual labor effected by the use of machines, having collected information from farmers. It is pointed out that experiment station tests fail to show the actual difficulties encountered in various soils and with unskilled management.

A gasoline-motor-propelled roller (*Sci. Amer. Sup., 61 (1906), No. 1571, p. 25172, fig. 1*).—A small and compact 3-ton roller which can be weighted with 10 cwt. of water by filling the back roller. Two speeds are provided, and the machine is readily reversed, making it adaptable to all kinds of road work. It is made in England, and is said to be the first application of gasoline for a roller.

Producer gas and gas producers (*Tradesman, 54 (1906), No. 9, pp. 114, 115*).—A paper read before an engineers' society by S. S. Wyer, giving an outline of the origin of producer gas, and modern methods of making and cleaning it for use in gas engines. The writer believes that "it presents the easiest and most practical solution of the elimination of the smoke nuisance. It will also show a marked economy in labor, fuel, and water consumption, standby and distribution losses, and the handling of peak loads . . . and the time will soon come when we will have producer gas locomotives and portable engines."

AGRICULTURAL EDUCATION.

Second International Congress of Agricultural Education (*2. Cong. Internat. Enseig. Agr., 1905, vols. 1, Raps. et Doc. Prél., pp. 692; 2, Compt. Rend., pp. 163*).—This is a report in two volumes of the work of the Second International Congress of Agricultural Education, held at Liège, Belgium, July 28–29, 1905.

Volume 1 contains reports and preliminary documents relating to the work of the 4 sections: (1) Higher agricultural education, (2) secondary agricultural education, (3) popular agricultural education, and (4) various means of disseminating information concerning agricultural science. In the first and third sections are given reports, opinions, and resolutions presented or adopted at 7 preceding international congresses of agriculture and at the First International Congress of Agricultural Education, held at Paris in 1904. In the section on higher agricultural education 35 papers were presented by delegates representing 14 countries of Europe, the United States, Japan, and the German colonies. In these papers are discussed systems of agricultural education; the work of particular agricultural institutions; agricultural courses in general; and particular phases of instruction in agriculture, such as agricultural mechanics, economic entomology, zootechny, tropical agriculture, rural economy, zoology as applied to agriculture, etc.

The papers presented at the section on secondary agricultural education differ materially from those presented at the first section, in that only one of the 11 papers discusses the work of a particular institution (the Provincial School of Agriculture, Barcelona, Spain). The other papers are taken up with discussions of the educational value of secondary courses in agriculture, desirable features of such courses, qualifications of teachers, agricultural schools for women, etc.

At the section on popular education 20 papers were presented. These discuss such topics as traveling schools, agricultural instruction in primary schools, courses for farmers, courses in agriculture for soldiers, and the service of agronomes. The papers presented at the fourth section are devoted to the discussion of reading circles, agricultural libraries, agricultural journals, lantern slides, lectures, and other means of disseminating information.

Volume 2 of the report is taken up with the proceedings of the congress.

What a university farm is for, L. H. BAILEY (*California Sta. Circ. 15, pp. 4*).—An excerpt from an address previously referred to editorially in this journal (E. S. R., 17, p. 216).

The prospect for education in horticulture, L. H. BAILEY (*Reprinted from West. N. Y. Hort. Soc. Proc., 51 (1906), pp. 7*).—A paper presented before the Society at its annual meeting in January, and published as a separate from the proceedings.

The author holds that at present our colleges are trifling with the subject of horticulture and teaching those things that are easily demonstrable rather than entering into the core of the matter. The college department of horticulture should have at least three strong divisions—pomology, floriculture, and the nursery business. The laboratory work in each of these departments should cover the whole theory and process of the given art. The pomological division should be a laboratory of perhaps 50 acres of actual orchards, in which every phase of the work from start to finish might be in natural operation. Floriculture as well as the nursery business should be taught by men not only thoroughly grounded in the principles of these subjects, but skilled on the craft side as well.

The manufacturing side of horticulture, such as canning, preserving, and evaporating vegetables and fruits, making jellies, juices, and other secondary products, is not yet taught in any institution, and sooner or later must form a part of the instruction in the department of horticulture. The higher institutions of learning, it is held, should teach the trades, or teach in preparation for them, as well as the professions, providing, always, that the method be such as to educate broadly at the same time.

Farmers' institutes (*Ohio Sta. Circ. 44, pp. 4*).—A list of station officers and the subjects each is prepared to discuss at farmers' institutes.

Why the friends of agricultural progress believe that agriculture should and will be taught in the public schools, A. C. TRUE (*California Sta. Circ. 17, pp. 14*).—A paper read at the joint session of the California Teachers' Association and the State Farmers' Institute at the University of California, December 26–29, 1905.

The subject is discussed from two points of view: (1) The economic, social, and educational needs of agriculture and agricultural people as related to the present civilization, and (2) the pedagogical requirements of a school system which shall be adapted to the masses of people in a democratic and industrial State and to the symmetrical culture of the mind and body of the human child.

Agriculture in the common schools, J. H. BLUFORD (*South. Workman, 35 (1906), No. 2, pp. 107–111*).—An address delivered before the North Carolina Teachers' Association at Greensboro.

Elementary agriculture, A. B. GRAHAM (*Normal Instr. and Teachers' World, 15 (1906), No. 4, pp. 9–11, figs. 5*).—This is a plea for nature study and agriculture in the rural school. It includes a discussion of the nature of work to be undertaken, suggestions for correlating agricultural work with geography, arithmetic, language, drawing, and the social life of the pupils, and hints concerning the training of teachers for such work.

Teaching of agriculture in public schools, T. L. LYON (*Univ. [Nebr.] Jour., 2 (1906), No. 5, pp. 6, 7*).—After commenting briefly on the lack of instruction in rural schools relating to the lives and occupations of the pupils, the writer gives two reasons why agriculture should be taught in high schools. "First, it contains the material with which to build a course of study second to none in educative and esthetic value; and, second, it may treat of a line of work vastly more practical and tangible than any other to the agricultural people of our State."

Instruction concerning soil and soil moisture is mentioned as of the greatest importance for Nebraska conditions, this to be followed by some attention to field crops, stock raising, dairying, and horticulture, keeping in mind that special emphasis should be given to those phases of agriculture most in vogue in the homes of the particular parts of the State in which the students live. Well-directed laboratory

work is mentioned as one of the means whereby school work may be freed "from its mechanical grind—its repetition of words and sentences without the thought content." General suggestions concerning the nature of laboratory work are given.

The advisability of agricultural education in elementary schools, L. H. BAILEY (*Agr. of Mass., 1904, pp. 93-120*).—This includes an address by L. H. Bailey, with discussion.

The first speaker, in giving reasons why young men leave the farm, suggested lack of business opportunity on the farm, ambition for large things, opportunity to work for others without financial risk, the attraction of more money, shorter hours, and social and intellectual entertainment in the city, and the influence of his early teaching. This last includes parental influence, that of the preacher, and that of the teacher. The farmer often deplores his own business, the preacher until quite recently has confined himself largely to the sphere of morals and religion, and the teacher, as a rule, has very little touch with rural affairs. She has been trained from the town and city point of view, and the books she uses employ not the problems of the farm, but the problems of the city. Suggestions for remedying some of the faults of teaching are pointed out and reasons given for teaching agriculture.

Hints and helps for young gardeners, H. D. HEMENWAY (*Hartford, Conn., 1906, pp. 59, figs. 17, dgm. 1*).—A guide for school and home gardeners intended for those who are young either in years or in experience.

Following an introductory chapter in which the value and influence of gardening are discussed, chapters on the following subjects are given: How to plan the garden, soil tillage, how to test seeds, how to plant, how to dig and set trees, how to make a hotbed and care for the same, strawberry culture, asparagus culture, and window gardening. The chapter on how to plant contains planting tables for vegetables and flowers in which is condensed much valuable information concerning the time, place, and manner of planting; how long it takes each plant to produce flowers and mature seed or to produce edible portions, and in the case of vegetables what part is eaten, how it is prepared for eating, and what the cultivation of each plant teaches.

A course in nature study, F. L. STEVENS and MRS. F. L. STEVENS (*N. C. State Supt. Pub. Instr., Teachers' Bul. 5, pp. 32*).—An outline is given for nature-study work by months, extending through 7 grades of elementary school work. This is followed by suggestions for elaborating the nature-study outline, in which one lesson is treated in considerable detail.

It is recommended that during each month at least one lesson be conducted upon each of the following subjects: Plants, animals, soil, and sky. The object of the work, as stated in the introduction, is not primarily to give information or knowledge, but "to arouse an interest in nature; to put the pupil in a sympathetic attitude toward nature for the purpose of increasing the joy of living."

How to teach the nature-study course, J. DEARNESS (*Toronto: Copp, Clark Co., Ltd. [1905], pp. 206, pls. 5, figs. 41, dgm. 1*).—This is a text-book prepared to aid teachers in presenting that part of the prescribed school courses of Nova Scotia, Ontario, and Manitoba relating to nature study and school gardening. Nature study is first treated in a general way and then taken up with reference to the prescribed courses which are outlined by grades and subject-matter. A list of publications useful for study and reference is given.

Nature study with common things, M. H. CARTER (*New York, Cincinnati, Chicago: American Book Co., 1904, pp. 150, pls. 18*).—This is a laboratory guide of nature study treated from the viewpoint of elementary science. It is intended for pupils in fourth, fifth, or sixth years of city schools.

Studies of 17 common fruits and vegetables are presented, each to be examined in its entirety, in cross section, and in vertical section. There is a sameness of treatment throughout, and, in the author's own words, "many of the observations the pupil is called upon to make in these lessons bear upon no conclusion. They make no attempt to explain anything but are for the sole purpose of being made."

MISCELLANEOUS.

Experiment Station Work, XXXIII (*U. S. Dept. Agr., Farmers' Bul. 244, pp. 32, figs. 6*).—This number contains articles on the following subjects: Handling seed corn; adaptation of seed corn; effect of root nodules on composition of crops; fumigation of nursery stock; cooking quality of potatoes; food value of cottage cheese, rice, peas, and bacon; methods of feeding poultry; extermination of cattle ticks; and covered yards for cows.

The sanitation of a country house, H. B. BASHORE (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1905, pp. VI+103; rev. in Nature [London], 73 (1906), No. 1897, p. 437*).—A short nontechnical treatise on the sanitation of the American country home.

Farm hygiene, P. REGNARD and P. PORTIER (*Hygiène de la Ferme. Paris: J. B. Baillière & Son, 1906, pp. 477, figs. 168; rev. in Mois Sci., 8 (1906), No. 3, p. 7*).—One of the volumes of Encyclopédie agricole published by G. Wery.

Accessions to the Department Library, 1905 (*U. S. Dept. Agr., Library Bul. 58, pp. 64*).

NOTES.

Connecticut Storrs Station.—C. D. Jarvis, a graduate of the Ontario Agricultural College and of the University of Toronto, who has been pursuing advanced work at Cornell University, has been appointed assistant horticulturist to the station, and entered upon his duties early in June. H. D. Edmond, instructor in chemistry and physics in the college, has been appointed station chemist.

Hawaii Station.—A proclamation has been issued setting aside lands at Hamakua, Hawaii, for a tobacco farm. Experiments to cover three years are planned, which will be carried out under the direction of the Federal station. The funds for carrying on the farm are to be supplied by private parties.

Louisiana Stations.—Clifford Waldron, farm manager at the sugar station at Audubon Park, has resigned to accept a position in connection with an extensive sugar establishment in Antigua. He will be succeeded by A. E. Dodson. Dr. G. D. Harris, of Cornell University, has been elected to the chair of geology in the State University, and will divide his time between university duties and the direction of the geological survey of Louisiana.

Maine University and Station.—The "Maine Farming Special," run under the auspices of the college of agriculture and the experiment station over the Bangor and Aroostook Railroad, proved a great success. Thirty-one stops of two hours each were made, and eleven evening exhibitions were given. More than 20,000 people visited the train and listened to the addresses. A similar trip was run over the Maine Central Railroad in June.

The university is giving increasing attention to agricultural extension, and A. W. Gilbert, a graduate of the Massachusetts Agricultural College and of Cornell University, has been placed in charge of this work. Reading and correspondence courses on sixteen different topics are now offered. Efforts are being made to introduce instruction in agriculture and forestry into all of the normal schools of the State. It is now taught in the normal schools at Castine and Gorham, and it is planned to start the work in a small way next year at Fort Kent, Presque Isle, and Farmington. Small tree nurseries will be started at each of the normal schools. The university will offer at its summer school, July 2 to August 3, a course in nature study for teachers.

W. M. Munson has been relieved of his duties as professor of horticulture in the university, and will devote his whole time to experiment-station work. His title in the station has been changed to orchardist instead of horticulturist. L. H. Merrill, professor of biological chemistry, will hereafter give his entire time to the station as chemist. A. C. Whittier, assistant chemist at the Massachusetts station, has been appointed assistant chemist to the station, and Miss Joanna C. Colcord assistant chemist, in place of I. Nurenburg, resigned. Roydon Hammond succeeds Bessie G. Tower as seed analyst and photographer.

New Jersey College and Stations.—The legislature has appropriated $24,000 for the establishment of short courses in agriculture, and $6,500 for the maintenance of the same. The college also received $27,000 due on scholarships for 1902-1905, and $12,000 on scholarships for the present year. The station was given an appropriation of $500 for the inspection of Paris green, and $13,500 for work on the extermination of mosquitoes.

Cornell University.—The traveling summer school of agriculture has been postponed, the requisite number of students not having complied with the requirements.

North Carolina College and Station.—C. W. Burkett has resigned his position as professor of agriculture in the college and agriculturist in the station, and will have charge of short agricultural courses at Ohio State University.

C. B. Williams, who has been connected for a number of years with field-crop work of the test farms under the State department of agriculture, has been added to the station staff. Provision has been made for an additional worker in plant breeding and forage crops, for a tobacco specialist, and an assistant in plant diseases who will give his entire time to the investigation of this subject.

Franklin Sherman, jr., formerly entomologist in the State department of agriculture and the experiment station, who has been connected with the Ontario Agricultural College during the past year, has returned, and R. S. Woglum, who has been acting entomologist in his absence, will be retained as his assistant. R. H. Harper and O. L. Bagley, assistant chemists, have resigned, to take effect September 1, and W. A. Syme, a former graduate of the college, has been appointed in this position.

Ohio Station.—Because of the increasing administrative work of the station, the office of assistant director has been established, and L. H. Goddard, experimentalist, has been appointed to that position. W. F. Pate, formerly assistant chemist in the University of Illinois, and L. L. La Shell have been appointed assistant chemists, and C. H. Kyle assistant agronomist.

Oklahoma Station.—John Fields has resigned the directorship of the station, to take effect October 1. This step has been in contemplation for several months, and is to enable him to give attention to private interests.

Oregon College and Station.—Mrs. Clara H. Waldo, of Macleay, has succeeded William E. Yates as a member of the board, and Austin T. Buxton, of Hillsboro, has succeeded B. G. Leedy. C. I. Lewis has been appointed horticulturist in the station.

South Dakota Station.—Frank A. Norton, assistant chemist, has resigned and has become associated with a laboratory for canning at Aspinwall, Pa.

Utah College and Station.—Funds have been set aside for the completion of the unfinished wing of the cattle barns and for the erection of an additional greenhouse. R. W. Clark, professor of animal husbandry, has resigned to accept a position with the Montana College and Station, and J. T. Caine, a graduate of the college, has been appointed in his place. J. W. Bolte, poultry manager, has accepted a position at the Rhode Island Station. J. A. Crockett, instructor in dairying, has also resigned to engage in private business. E. D. Ball, entomologist, has been granted leave of absence for one year to pursue his studies.

Vermont University and Station.—The corner stone of Morrill Hall, the new agricultural building, was laid June 26. W. J. Morse, assistant professor of botany, has been appointed vegetable pathologist to the Maine Station and will enter upon his duties July 1.

Virginia College and Station.—D. O. Nourse, agronomist, retired at the close of the present college year, after many years of service, to engage in private business.

Washington College.—A four-year course in veterinary science has been established, leading to a bachelor's degree.

Wisconsin University and Station.—James Milward has been appointed assistant in horticulture, to take effect July 1. Leslie H. Adams, for many years farm superintendent at the college and station, has severed his connection with the institution.

According to a note in *Science*, plans for an agronomy building and an agricultural engineering building have been completed, and contracts for their erection are now being made. These contracts will provide for their completion before the beginning of the short course in agriculture next winter.

Wyoming Station.—R. E. Hyslop, a graduate of the University of Wisconsin and a postgraduate of the University of Missouri, has been appointed agronomist and will begin work July 1.

Hampton Normal and Agricultural Institute.—The Shellbanks Farm, which has hitherto been conducted almost entirely on a commercial basis, has recently been turned over to the agricultural department under the direction of Prof. E. C. Bishop, and will henceforth be utilized largely for the instruction of agricultural students. A special three-year course has been inaugurated for those who wish to take agriculture as their main work, and each boy who undertakes the course will put in seven hours of every school day in actual field work under the direction of an instructor, and will also receive two hours of theoretical agriculture and occasionally some night work.

Policy of the Carnegie Foundation.—The trustees of the Carnegie Foundation for the Advancement of Teaching have announced the policy of the foundation, through an article by Henry S. Pritchett in *Educational Review* for June, 1906. The question as to the admission of State institutions to the benefits of the foundation has been left to be decided at the annual meeting of the trustees in November next.

In this connection it is recognized that "from the standpoint of education there are serious objections to the recognition in a State like Wisconsin, for example, of a modest college and the omission of the great State university, which is the real center of high education. On the other hand, an important question of general public policy is involved when a private agency steps in between the State and an institution which the State has founded and controls. For nearly a half century the great State universities in the Central West have labored to establish the principle that higher education in their respective States is to be maintained by the State itself. This principle has been established, and these universities are soon to be in possession of the largest incomes which any institutions in America receive. The State may, therefore, fairly be expected to provide a retiring-pension system for its own professors."

The decision of this matter will be awaited with much interest, as it will affect a large proportion of the workers connected with the agricultural colleges and experiment stations of the country.

The International Agricultural Institute.—A recent number of *Revue Scientifique* states that in spite of pessimistic predictions the future of this Institute is assured, since the following countries have signified their intention to cooperate in its establishment: Italy, France, England, Russia, Germany, Austria-Hungary, United States, Japan, Belgium, Holland, Switzerland, Spain, Portugal, Denmark, Sweden, Greece, Luxemburg, Servia, Bulgaria, Egypt, Persia, Mexico, Equador, Uruguay, Nicaragua, Cuba, and San Salvador, and other powers have signified their intention of cooperating. It is expected that, in accordance with the wish of King Victor-Emmanuel, the new palace in Rome will be completed in 1907, and the following year the work of the Institute will commence.

Agriculture at Cambridge University.—The board of agricultural studies reports that the Worshipful Company of Drapers, to whom it is already indebted for the endowment of the chair of agriculture, has offered \$25,000 toward the buildings required by the agricultural department, on condition that an equal sum be raised by the end of the year. Pledges of \$5,000 each have already been received from four persons.

Agricultural High School of Berlin.—A chair of fishery and fish breeding has been established at the Agricultural High School of Berlin and will be occupied by Dr. P. Schiemenz, director of the Müggelsee Biological Station, which now becomes a department of the Agricultural High School.

Agricultural Continuation School in Germany.—The first agricultural continuation school in the Province of Brandenburg was opened at Jessern last November and continued until the end of March. Fourteen students were in attendance, and the high grades which they maintained in the examinations at the close of the term indicated that the experiment was entirely successful. The subjects taught were

chemistry, soils, fertilizers, and feeding. It is planned to supplement the winter courses by Sunday afternoon lectures during the summer months, and to keep some oversight of the students in their practical work at home. The school was opened at the request of sons of property owners in Jessern and Goyatz, who also bore the cost of instruction.

School of Agriculture, Cedara, Natal.—The Cedara School of Agriculture, which was opened to students in the spring of 1906, provides a 2-year practical course in which students spend about 4 days a week in practical work in the field and workshop, and the remainder of the time in the study of such subjects as forestry, horticulture, dairying, veterinary science, entomology, agricultural chemistry, mathematics, bookkeeping, and surveying. The school is provided with a new building containing 2 stories and a basement, the latter devoted to laboratories, kitchen, etc., the first floor to dining hall, library, and offices, and the second floor to dormitories and a large lecture hall.

Children's Corn and Cotton Contest in Georgia.—The Georgia State College of Agriculture and Mechanic Arts has arranged for children's contests in growing corn and cotton during the summer of 1906. These contests are open to schools or to pupils growing corn or cotton at home. County exhibits of the crops grown will be held during the month of October prior to the State Fair, and the contestants winning prizes in the county contests will be allowed to send their exhibits to the State Fair to enter competition for State prizes.

Irish Training School of Domestic Economy.—The Department of Agriculture and Technical Instruction for Ireland announces that in July, 1906, it will award 10 open scholarships and 10 limited scholarships to assist domestic economy students at the Irish Training School of Domestic Economy, Dublin. These scholarships will entitle the holders to free admission to the full course of training for teachers of subjects in domestic economy. Arrangements have also been made by the Department for the reception of a small number of students at St. Mary's Convent of Mercy, Portumna, to pursue studies in dairying, poultry keeping, horticulture, household management, cookery, laundering, etc.

Monthly Weather Review.—The editor of the *Review*, Prof. Cleveland Abbe, U. S. Weather Bureau, invites librarians of agricultural institutions to inform him promptly as to what numbers or volumes of the *Review* are needed to complete their sets of this periodical. He will be glad to supply the necessary numbers and volumes as far as possible.

Miscellaneous.—A bill appropriating $80,000 to St. Lawrence University for the establishment of an agricultural course and $12,000 for maintenance has been passed by the New York legislature and signed by the governor.

According to *Mark Lane Express*, the establishment of an agricultural college for Devon (England) is being considered under the Seale Hayne bequest.

Hon. W. T. Harris, commissioner of education, has resigned, and Dr. E. E. Brown, professor of the theory and practice of education in the University of California, has been appointed his successor.

Director M. A. Scovell, of Kentucky received the degree of doctor of philosophy from the University of Illinois at commencement.

Dr. W. C. Sturgis, formerly botanist at the Connecticut State Station, has been appointed dean of the new school of forestry, established in connection with Colorado College, to which reference has previously been made (E. S. R., 17, p. 722).

H. D. Hemenway, for a number of years director of the School of Horticulture, Hartford, Conn., has severed his connection with that institution and during the summer will conduct a course in nature study for teachers in the Woodland Farm Camp School, at Westchester, Conn.

EXPERIMENT STATION RECORD.

VOL. XVII. JULY, 1906. No. 11.

The friends of agriculture will learn with sincere regret of the death of Hon. H. C. Adams, of Wisconsin, which occurred at Chicago, July 9, 1906.

Mr. Adams had shown himself to be a most earnest and intelligent friend of agricultural progress, whose varied interests had for many years received his active cooperation and support. As a member of the committee on agriculture of the House of Representatives, he brought to his work wide familiarity with the conditions and needs of agriculture, and judgment as to the means of accomplishing the desired ends, which made him an extremely useful man to the country at large. He was liberal and broad-minded in his conceptions, and active and aggressive in urging what he conceived to be for the common good. Although he took a prominent part in all matters relating to agriculture during his period of service in Congress, his success in securing the passage of the act for the further endowment of agricultural experiment stations stands out as a conspicuous feature of his public career, and has made him a National figure. This act placed him among the great benefactors of agriculture, along with Morrill and Hatch, and will serve as an enduring monument to his memory.

Mr. Adams' avowed intention when elected to Congress was to secure an increase of the appropriation for agricultural experiment stations. In this effort he showed not only an intelligent appreciation of the stations' work, but of the higher work in agricultural science, which must needs be quite limited under existing appropriations. Although not a student of science, he had become thoroughly imbued with the important relations of science in the development of agriculture, and he entertained high ideals for work on the frontiers of agricultural science.

The successful passage of the act which bears his name, after several years of labor in its behalf, was a matter of great satisfaction to him, and he took a keen interest in the preparations for its use. He was called just as the stations were coming into the realization of its benefits and before work under it had fairly been instituted. In the death of Mr. Adams the Federal Department of Agriculture, the experiment stations, and agricultural progress as a whole lose a strong and efficient advocate and supporter.

The appropriation for the U. S. Department of Agriculture for the fiscal year 1907 nearly reaches the ten million mark. The regular appropriation amounts to $9,560,440, and to this is added emergency appropriations aggregating $372,500. The grand total, $9,932,940, represents an increase of $3,050,250 over last year.

A large proportion of this increase is, of course, due to the funds provided for carrying into effect the new meat inspection law, but apart from this the appropriation is larger than last year by over $900,000. Most of the changes came independently of the Department and as the result of popular demand, the emergency appropriations and a considerable number of other items being urged by outside interests. As a matter of fact, the total appropriation, excluding the increased amount for meat inspection, exceeds the estimates of the Secretary of Agriculture by $156,730.

The act embodies an unusual number of new features, several of which are of interest as inaugurating new policies. It marks a growth of confidence in agricultural work and in the Department, and voices an increasing sentiment for Governmental supervision of certain large undertakings, administrative and otherwise, which affect the whole country and are not at present provided for by local agencies.

The Bureau of Animal Industry now leads all other branches of the Department in the amount of its appropriations—$3,946,980. This figure does not include an emergency appropriation of $82,500 for experimental work looking to the eradication of Texas fever ticks, which is to be carried on in cooperation with State authorities. The chief interest in the appropriation for this bureau naturally centers around the new meat inspection law, concerning which there has been so much discussion in the public press. The execution of this law will call for material expansion of the bureau's work in this direction. For this the new law makes a permanent annual appropriation of $3,000,000. Although no specific amount has been mentioned for meat inspection in previous appropriations, about $850,000 a year has been expended, so that the net increase for this purpose is about $2,150,000.

Among other new duties the Bureau is authorized to make tests of tuberculin serums, antitoxins, etc., of domestic and foreign manufac-

ture, which are sold in the United States for the detection, prevention, treatment, or curing of diseases of domestic animals; and is also given $5,000 to conduct experiments in the diseases prevalent among domestic animals in Minnesota and adjoining States, in cooperation with the Minnesota Experiment Station, with a view to developing antitoxin or preventive vaccines. Twenty thousand dollars is specially designated for "further developing the dairy industry of the Southern States, by conducting experiments, holding institutes and giving object lessons, in cooperation with individual dairymen and State experiment stations."

The amount appropriated for the Weather Bureau is $1,439,240, an increase of $46,250. The work provided for does not involve any particularly new features.

The largest increase, except in the case of the Bureau of Animal Industry, is for the Bureau of Plant Industry, $142,860, making the total $919,740. To this should be added an emergency appropriation of $105,000 for continuing work against the cotton-boll weevil by encouraging the diversification of crops and improved cultural methods, breeding new cotton, etc. Some of the new features provided for in this Bureau are the provision for inspection of grain at certain points of export, for which $15,000 is named, a special investigation of parasites and orchard diseases prevalent in the Ozark Mountain region, with a special appropriation of $5,000, the erection of a laboratory and office building at the plant introduction garden at Chico, California, and $3,500 for the improvement and macadamizing of gravel roadways in the Department grounds. The provision for the purchase of seeds for Congressional distribution, which was eliminated by the House of Representatives but was restored in the Senate Committee on Agriculture, remains $242,920, of which as formerly $37,780 is for the introduction of seeds and plants from foreign countries.

The Forest Service is given a round million, which is an increase of $124,860 over last year. Under the emergency appropriations $15,000 is provided for the erection of a wire fence on the Wichita Forest and Game Preserve, to provide a range for the buffalo herd presented by the New York Zoological Society; and $2,500 for a building on Dismal River Forest Reserve in Nebraska. A new and important feature affecting the policy of the Government with reference to the forest reserves is incorporated in the act. This authorizes the payment each year of 10 per cent of the money received from these reserves to the State or Territory in which the reserves are respectively located, to be expended by the legislature for the benefit of the public schools and public roads of the county or counties in which the reserves are situated. This provision is looked upon with much favor, as it will in large measure offset the loss to the counties due to the withdrawal of land from settlement and ultimate taxation.

Under the present method of administering the forest reserves they

have become a considerable source of revenue. During the past fiscal year the proceeds from these reserves amounted to $767,219.96. Of this amount $203,443.27 was derived from sales of timber, $39,224.96 from "trespass," on account of timber previously cut but not paid for, and $514,086.74 for grazing. It is confidently expected that in a few years these reserves will not only be self-sustaining but will return a considerable revenue over their cost of management.

The total for the Office of Experiment Stations, including the $720,000 for the State experiment stations under the Hatch Act, is $974,860. The general maintenance fund of the Office is increased to $25,500, aside from the statutory salaries. The special appropriation of $3,000 for Alaska, for the purchase and introduction of live stock for experimental purposes, is continued, and the Hawaii Station is given $5,000 additional to provide a suitable water supply. There is an increase of $48,000 for irrigation and drainage investigations, making the total for that purpose $122,200, and the field of the Office is broadened to include agricultural education, the act authorizing the promotion of elementary education in agricultural schools.

The total appropriation for the Office, aside from the amount carried for the State stations, is $254,860, an increase of $56,960 over last year. A clause in the act authorizes the Secretary of Agriculture to turn over to the Georgia Station the buildings and machinery at Waycross, Ga., which were used by the Department in the study of the production of table sirup, the condition being that the Georgia Station shall establish and maintain a substation at Waycross in the interest of the sirup and other agricultural industries in that part of the State.

In reality the act authorized the expenditure of $240,000 which does not appear in any of the totals. This was on account of the Adams Act, increasing the Federal appropriation for the State experiment stations. Under the opinion of the Comptroller, this act would not have gone into effect until the fiscal year 1907, but it was construed by the agricultural bill to appropriate $5,000 to each State for the fiscal year ending June 30, 1906, and following this construction the Treasury Department made these advances as soon as possible after the passage of the agricultural bill. This amounted to $240,000 in all, a part of which will doubtless remain unexpended, owing to the late date in the fiscal year on which the bill passed. A considerable proportion of the stations, however, were enabled to secure necessary permanent equipment and the like for investigation to be undertaken with the new act, and the work will thus be started on a larger and more effective scale than would otherwise be possible, especially as the amount for the present year is increased to $7,000.

For the Bureau of Chemistry the appropriation is $174,180, an increase of $19,180 over last year. The Bureau of Entomology receives $94,610, an increase of $10,140, of which $5,000 is for investi-

gating the white fly affecting the orange groves of Florida. It also has an emergency appropriation of $85,000 for its cotton-boll weevil investigation, and of $82,500 for establishing a quarantine against the further spread of the gypsy and brown-tail moths in New England, in cooperation with the authorities in the different States concerned. The fund for the Bureau of Soils is increased $16,800, making the total for this year $221,460; that for the Bureau of Statistics amounts to $210,560; and for the Biological Survey $52,000, the same as last year.

The Office of Public Roads receives $70,000, an increase of $20,000, and the Division of Publications $248,520, including, as usual, $98,750 for the preparation and printing of Farmers' Bulletins. Other items are: Office of the Secretary, $113,200; Library, $25,880, an increase of nearly $5,000; Division of Accounts and Disbursements $32,210, and contingent expenses, $37,000.

The new allotment to the Department from the printing fund is $300,000 instead of $185,000 as formerly. This increase is apparent rather than real, as the $115,000 added is intended to compensate for certain changes in the printing law which place a large share of the expenses for the Yearbook, annual reports, and the like upon the Department. This fund, together with the proceeds from the forest reserves, which are available for the use of the Forest Service and are to be taken into account in future estimates, makes the total income of the Department for the fiscal year 1907 over eleven million dollars.

The growth of the Department in police or inspection duties is one of the most salient features of the development of the past year. The largest of these undertakings at present is the inspection of meats and packing houses. The agitation for more thorough control of the packing industry, with representations as to the inadequacy of the laws in force and the insufficiency of the appropriations for carrying them into effect, resulted in the passage of a law which is said by experts to be the broadest and most stringent of its kind in force in any country. Rarely has the weight of public sentiment been more forcibly felt in legislation than in the case of this law.

The law provides for ante-mortem and post-mortem examination of animals intended for meat, and of the products at various stages, all parts found to be "unsound, unhealthy, unwholesome and otherwise unfit for human food" to be destroyed for food purposes in the presence of an inspector. The inspection is extended to canned and otherwise prepared meats, which are required to bear the label showing that they have been inspected and passed, the same as in the case of fresh meat. The law directs that all products shall be condemned which contain dyes, chemicals, preservatives, or ingredients injurious to health, except when packed for export to a foreign country with whose laws such treatment does not conflict.

An important provision is that for a sanitary inspection of the packing establishments themselves, authorizing the Department to prescribe the rules and regulations of sanitation under which they shall be maintained, and to withhold the inspection label from the products of establishments which do not meet these requirements. The inspection label is a requisite to shipment of meat or meat products from one State to another, or to a foreign country, so that transportation companies are made subject to the law; and the inspection also extends to live cattle, sheep, swine, and goats intended for export. Penalties for violating the provisions of the law are fixed at a fine not exceeding $10,000 or imprisonment for not more than two years, or both. Heavy penalties are also provided for bribery of inspection officials, or the acceptance of a bribe. Farmers and retail butchers are exempted from the requirements of inspection.

Another important line of inspection work inaugurated by the last Congress is that in connection with the execution of the National pure food law. This law prohibits interstate commerce in foods which have been adulterated or misbranded, or which are unwholesome or contain preservatives or other additions making them injurious to health; and it also prohibits the manufacture or sale of such products in any Territory, the District of Columbia, or our insular possessions. It covers foods, condiments, beverages of all sorts, drugs, and medicines. Heavy penalties of fine or imprisonment, or both, are imposed for violations of the law, and condemned goods in process of transportation from one State to another, or to a foreign country, may be confiscated.

The Department of Agriculture is charged with the administration of the law, with the collaboration of the Treasury Department and the Department of Commerce and Labor. The burden of maintaining the inspection of food products under this law and of determining what constitutes adulteration, will fall upon the Bureau of Chemistry of this Department. No funds have yet been appropriated by Congress for carrying the law into effect, but considerable time will be required for drawing up regulations and making the necessary preliminary arrangements. Congress will be asked to make an immediately available appropriation when it convenes in December next. It is the expectation of the friends of the measure that it will very materially strengthen and supplement the efforts of the several States in stamping out the various forms of sophistication which have become so prevalent.

An important branch of inspection work for which only a beginning is provided by the appropriation act is the grain inspection. There was considerable agitation of this subject at the recent session of Congress, the contention being that provision should be made for an inspection by the Department of Agriculture of grain for export to

foreign countries, this inspection being for quality, condition, and grade, and to serve as the basis for an official certificate. The bulk of grain is now sold on the certificate of inspectors employed by boards of trade and similar agencies, and there is frequently a lack of uniformity in these certificates for similar lots. Questions arise as to the accuracy of the certificate and the condition and deterioration in transit, out of which dissatisfaction has grown which has affected our foreign trade.

The result of consideration of this matter was that the Secretary of Agriculture was authorized "to establish at such points of export as he may deem expedient, laboratories for the purpose of examining and reporting upon the nature, quality, and condition of any sample, parcel, or consignment of seed or grain." The amount named for this purpose was $15,000, which will obviously provide only quite limited facilities for such inspection, but will afford a court of appeal in doubtful or disputed cases. This is doubtless one of the features which will grow in extent as its importance and usefulness are realized, and may ultimately assume considerable proportions.

It will thus be apparent that the Department is adding to its administrative and investigational functions extensive and important inspection work, which is broadened to include not only the special interests of the farmers but the people as a whole.

33747—No. 11—06——2

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Introduction to the investigation of products important in agriculture, C. Böhmer (*Anleitung zur Untersuchung landwirtschaftlich wichtiger Stoffe. Berlin: Paul Parey, 1906, pp. VIII+135*).—This book is intended as a guide for students and teachers in agricultural-chemical laboratories.

The methods described are in the main those approved by the International Congress of Applied Chemistry and of the Association of German Agricultural Experiment Stations. The topics treated are mechanical analysis of soils; examination of commercial fertilizers, including methods of determining phosphoric acid, nitrogen, potash, and lime; examination of feeding stuffs; determination of the sugar content of beets; milk examination; chemical analysis of soils, including preparation of hydrochloric-acid solutions and their examination, fusion with alkaline carbonates and reduction by means of hydrofluoric-acid, and the determination of nitrogen; and preparation of solutions used in analysis.

Equilibrium between some bases when they are present simultaneously with phosphoric acid, A. Quartaroli (*Gaz. Chim. Ital., 35 (1905), II, pp. 290–304; Staz. Sper. Agr. Ital., 38 (1905), No. 7–8, pp. 639–657; abs. in Jour. Soc. Chem. Indus., 24 (1905), No. 23, p. 1229*).—The author reports studies of the conditions of equilibrium in the following systems: (1) $1H_3PO_4 + \frac{1}{2}CaO$ (or BaO) $+ 2KOH$ (or $NaOH$); (2) $1H_3PO_4 + \frac{1}{2}CaO$ (or BaO) $+ 1NaOH$; (3) $1H_3PO_4 + \frac{1}{2}MgO + 2NaOH$ (or KOH); (4) $1H_3PO_4 + \frac{1}{2}MgO + 1NaOH$ (or KOH).

In the experiments which are reported 25 cc. of a normal solution of phosphoric acid was mixed with corresponding amounts of the alkaline solutions and the whole made up to 500 cc. An aliquot of the solution was filtered immediately and the filtrate titrated with twice-normal hydrochloric acid in presence of methyl orange and phenolphthalein. After standing for 2 days another portion of the solution was filtered and titrated in the same way.

"In system (1) barely one-third of the phosphoric acid present is precipitated, in the form of tri- and tetrabasic salts, and not two-thirds in the form of a double salt $Ca_3(Ba_3)Na_6(PO_4)_4$, as Berthelot stated. Two-thirds of the phosphoric acid remains in solution in the form of tri- and di-basic salts. The bases are distributed irregularly between the precipitate and the solution. If the system $1H_3PO_4 + \frac{1}{2}BaO + 2NaOH$ be allowed to stand for a long time, the precipitate ultimately contains one atomic proportion each of sodium and barium, and nearly one-half of the acid is precipitated. In system (2) also, the bases are distributed irregularly between the precipitate and the solution. The latter contains mono- and dibasic phosphates, whilst the precipitate contains di-, tri-, and, occasionally, tetrabasic salts. Less than two-thirds of the phosphoric acid is precipitated.

"Magnesia behaves differently from lime and baryta, and its behavior depends also on the kind of alkali present. For example, in system (3) when the alkali employed is sodium hydroxid, the precipitate consists solely of magnesium compounds, whilst when potassium hydroxid is used, some alkali is carried down by the precipitate. In system (4) much less phosphoric acid is precipitated (only about

one-sixth of the total quantity); apparently a soluble double phosphate is formed, as dimagnesium phosphate is insoluble, and the amount of alkali present would be sufficient for the precipitation of the remaining dissolved magnesium under ordinary conditions."

The reactions of the three phosphoric acids, C. ARNOLD and G. WERNER (*Chem. Ztg., 29 (1905), No. 104, pp. 1326, 1327; Analyst, 31 (1906), No. 360, pp. 92, 93*).—The authors' tests of published reactions having shown them to be generally unreliable, a new series of tests with the alkali salts of ortho-, pyro-, and metaphosphoric acids is given.

On the compounds of pyrophosphoric acid, J. CAVALIER (*Compt. Rend. Acad. Sci. [Paris], 142 (1906), No. 15, pp. 885–887*).—Four series of salts of this acid, which is taken to be tetrabasic ($P_2O_7H_4$), are briefly described. Studies of the vapor densities of a series of alcoholic pyrophosphates show that they have a molecular weight corresponding closely with the formula $P_2O_7R_4$.

On the determination of citric-acid soluble phosphoric acid in Thomas slag, II. FRESENIUS (*Landw. Vers. Stat., 64 (1906), No. 1, pp. 12–15*).—A brief review is given of studies of this method.

The determination of phosphoric acid in fertilizers as phosphomolybdic anhydrid, G. BERJU (*Jour. Landw., 54 (1906), No. 1, pp. 31–46; abs. in Chem. Ztg., 30 (1906), No. 24, Repert. No. 7, p. 94*).—This article reports a study of the accuracy of Neumann's method[a] as applied to pure phosphates and Thomas slag solutions prepared in various ways. The method is reported to have given accurate results under all conditions and is much simpler and more accurate than direct precipitation of phosphoric acid as magnesium-ammonium phosphate.

The determination of ammoniacal nitrogen in ammoniated superphosphates, SCHEELE and VON SOXHLET (*Landw. Vers. Stat., 64 (1906), No. 1, pp. 15–17*).—A brief account is here given of the discussion of methods for this purpose at the Munich meeting of the Association of German Agricultural Experiment Stations.

A simple method for the determination of nitric acid in nitrates, J. T. BORNWATER (*Chem. Weekbl., 3 (1906), pp. 30, 31; abs. in Chem. Centbl., 1906, I, No. 8, p. 703*).—In the method proposed the nitrate is reduced by means of potash solution and aluminium foil and the ammonia distilled in a Kjeldahl apparatus.

On the need of uniform methods of titration in the determination of nitrogen, B. SCHULZE (*Landw. Vers. Stat., 64 (1906), No. 1, pp. 35, 36*).—A brief account of the discussion of this subject at the Munich meeting of the Association of German Agricultural Experiment Stations, calling attention to lack of uniformity in kind and strength of acids and alkalis used and of the desirability of greater uniformity in these respects.

The determination of potash by means of perchloric acid (*Landw. Vers. Stat., 64 (1906), No. 1, pp. 6, 7*).—This method is described and its unanimous adoption by the Association of German Agricultural Experiment Stations is recorded.

The detection and determination of chlorate in sodium nitrate, L. GRIMBERT (*Jour. Pharm. et Chim., 6. ser., 23 (1906), pp. 98–100; abs. in Analyst, 31 (1906), No. 361, p. 128*).—Sodium nitrate is tested for presence of chlorate by shaking up the solution with 1 drop of anilin, and pouring a little strong sulphuric acid down the side of the tube. If chlorate is present an intense blue zone appears at the junction of the liquids. Chlorate is determined quantitatively by igniting the nitrate with a little cane sugar, extracting with water, and titrating for chlorids in the usual way.

On the gravimetric determination of calcium, O. BRUNCK (*Ztschr. Analyt. Chem., 45 (1906), No. 2, pp. 77–87, fig. 1*).—Comparisons of various methods—direct weighing, weighing as carbonate, sulphate, and fluorid—of determining lime are reported. Direct weighing gave the most unsatisfactory result—generally too high.

[a] Ztschr. Analyt. Chem., 37 (1898), p. 317.

The other three methods gave closely agreeing results and were about equally satisfactory. The fluorid method is probably the quickest and most satisfactory in the hands of beginners. For control purposes it is recommended to weigh first as carbonate and then convert into sulphate or fluorid.

Determination of lime in soils, D. J. Hissink (*Chem. Weekbl., 3 (1906), pp. 73–78; abs. in Chem. Centbl., 1906, I, No. 11, p. 961*).—Neubauer's method is recommended.

The analysis of foods. Simple and easy methods of detecting adulteration of food products and other domestic articles, C. Margeot (*L'analyse des aliments. Recettes simples et faciles pour découvrir toutes les falsifications des produits alimentaires et autres objets domestiques. Paris: E. Flammarion, pp. 188*).—As the subtitle states, this volume gives simple directions for the detection of adulteration of food products and other materials used in the home. The descriptive matter includes standards of quality of staple articles of food, the principal methods of adulteration and sophistication which are likely to occur, and methods of detection of adulteration.

The use of the immersion refractometer in food analysis, J. Hanuš and K. Chocenský (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 6, pp. 313–320, fig. 1*).—The experimental data described show that the immersion refractometer may be used to determine the amount of caffein present in aqueous solution quickly and accurately.

Maple sirup and maple sugar investigations with particular reference to the detection of adulteration, C. H. Jones (*Vermont Sta. Rpt. 1905, pp. 315–339*).—A number of samples of maple sugar and sirup, maple cream, and brown sugars were examined with special reference to the amount and character of the ash present, the malic acid value, the amount of precipitate obtained with lead subacetate, and other characteristics, the object of the investigations as a whole being the detection of adulteration, particularly with cane and beet sugar products.

According to the author, the minimum standards which seem warranted when applied to a filtered sirup weighing 11 lbs. to the gallon are not less than 0.50 per cent total ash, not less than 0.15 per cent insoluble ash, not less than 0.40 per cent malic acid value, nor less than 1.00 cc. for the lead subacetate precipitate.

If an examination of an original sample shows that one or all of such salient factors are below the minimum, the samples should be boiled to a uniform basis of concentration and filtered. It would seem, the author states in effect, that a certain minimum amount of ash can not be removed from pure maple sirup or maple sugar made into sirup, by the ordinary methods of filtration, and that even slow and complete filtering fails to remove sufficient ash from the pure goods to admit even a suspicion of adulteration.

The ash of pure maple goods consists largely of carbonates of potassium and lime with relatively small and varying quantities of sulphates and phosphates. The determination of the sulphates, according to the author, is of use at times in detecting adulteration since they are present in relatively large amounts in many commercial brown, cane, and beet sugars.

"The amounts of lime and potash also afford data useful in judging the purity of suspected samples. Owing to the work involved these determinations are needful only in important cases when other tests do not furnish convincing data.

"It has been observed that the percentage of sulphates appears to be greater in maple sirup than in maple sugar, although no explanation has been offered. In the writer's opinion, it may be accounted for as follows: The percentage of ash, soluble in water, is greater in sirups than in sugars. . . . This is due entirely to the larger quantity of malate of lime (insoluble ash) in the sugar. As sulphates are found largely in the soluble ash, they would therefore average greater on an ash basis in sirups than in sugars.

"The author has yet to see a pure maple sirup that, even after souring or long keeping under any reasonable conditions, will not furnish an abundant maple aroma on boiling after dilution with water. The flavor or taste of maple goods may serve in a measure to indicate their purity. Inasmuch as many pure maple sirups, particularly those produced in certain sections of the country, have what might be termed a 'molasses taste,' it is best not to form hasty opinions from this sense alone, especially if the origin, age, and conditions of manufacture are not known. The flavor taken into consideration with color is a good criterion as to quality of maple products." (For earlier work see E. S. R., 17, p. 219).

The examination of honey, H. MATTHES and F. MUELLER (*Ber. Nahrmtl. Untersuch. Amt. Jena, 1903–4, pp. 37–45; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 9 (1905), No. 12, pp. 739–741*).—Detailed directions are given for determining the different constituents and constants desirable in an analysis of honey, a feature of the work being the recommendation that a uniform solution of honey be used in every case. The author prepares the solution by dissolving 5 gm. of warm well-mixed honey in 50 gm. of warm water and then diluting to 150 gm. The results of the analyses are all expressed on the dry-matter basis.

Concerning starch, glycogen, and cellulose, Z. H. SKRAUP (*Monatsh. Chem., 26 (1905), No. 11, p. 1415; abs. in Zentbl. Physiol., 20 (1906), No. 1, pp. 1, 2*).—The chlorazetyl products of starch, glycogen, and cellulose were made by treatment with acetic-acid anhydrid saturated with hydrochloric acid.

From the chlorin content of the bodies formed it is possible to secure data regarding molecular weight. The calculated molecu ar weight for soluble starch was 7,440, which implies that the starch formula is 46 to 50 times $C_6H_{10}O_5$. The calculated molecular weight for glycogen was 23,630, which would imply a very complicated molecular structure. The values obtained for cellulose from filter paper indicate that the formula is not higher than for soluble starch, perhaps $(C_6H_{10}O_5)_{34}$.

Chemistry of the albumens, S. B. SCHRYVER (*Philadelphia: P. Blakiston's Son & Co., 1906; rev. in Jour. Amer. Chem. Soc., 28 (1906), No. 5, pp. 658–660*).—The present knowledge of the chemistry of proteids is summarized.

"Facts relating to the solubility, physical properties, precipitation by salts, coagulation, behavior toward acids and bases, etc., which have, in the past, formed so large a part of the accounts that have been written of these bodies occupy in this book but a very insignificant place. This fact shows the great progress made during the past five years in our knowledge of the chemical side of this subject, for it is now possible to give a condensed account of the purely chemical facts that are known which is sufficiently extensive to warrant their publication in a separate volume."

A considerable part of the volume is taken up with the chemistry of the nucleic acids and their decomposition products, especially the purin and pyrimidin bodies, which bear no chemical relation to the protein molecule proper. "The only reason for including the nucleic acids is the fact that they are always found in nature together with the proteins or the protamins. This practice, while convenient for those familiar with the proteins, leads to confusion among those who take only a general interest and read such books as the one under consideration in order to obtain a general knowledge of the chemistry of the proteins."

Crude gluten, F. A. NORTON (*Jour. Amer. Chem. Soc., 28 (1906), No. 1, pp. 8–25*).—According to the author's investigations "crude gluten consists of about 75 per cent of true gluten—gliadin and glutenin—together with small percentages of nongluten proteid, mineral matter, fat, starch, fiber, and other nonproteid matter.

"The relation of the crude gluten content to that of total protein (N × 5.7) varies with the character of the flour, the crude gluten content being greater than total protein for straight and low-grade flours, nearly the same for patent flours, and less for whole-wheat meal.

"Crude gluten is an expression, in addition to the true gluten content of a flour, of the balance between the loss of nongluten proteids and gain from the retention of nonproteid substances. The relation of the crude gluten content to the total protein content can thus be explained by the varying composition of the different flours in respect to nitrogenous compounds and nonproteids.

"Crude gluten is a very rough expression of the gluten content of a flour or wheat and the determination has but little worth in the valuation of flours.

"The determination of total nitrogen and gliadin nitrogen with expression of the ratio of gliadin to total protein (N × 5.7) seems to be the best simple method at hand for estimating the gluten content and ascertaining the character of the gluten in the valuation of wheats or flours."

Determining the sulphurous acid in meat, C. MENTZEL (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 6, pp. 320–324*).—In a number of cases the distillation method showed the presence of small amounts of sulphurous acid (5 to 7.8 mg.) in chopped meat when it could not be identified by means of potassium-iodid-starch paper.

The estimation of undigested protein in feces by means of thiosinamin acid, E. ROSENBERG (*Arch. Verdauungskrank., 11, p. 321*).—Oefele's method of estimating undigested protein is, according to the author's investigations, not reliable.

Concerning the composition of lecithin, M. WINTGEN and O. KELLER (*Arch. Pharm., 244 (1906), No. 1, pp. 3–11*).—Studies of the phosphorus and nitrogen content of lecithins of animal and vegetable origin are reported. The purity of lecithin can not be ascertained by determining the nitrogen and the phosphorus content alone. Whether the determination of the iodin value and the free fatty acid value will serve for the purpose must be determined by further investigation.

General and physiological chemistry of fats, F. ULZER and J. KLIMONT (*Allgemeine und physiologische Chemie der Fette. Berlin: J. Springer, 1906; rev. in Österr. Chem. Ztg., 9 (1906), No. 9, p. 128*).—A monograph on the chemistry of fats from the standpoint of theoretical and physiological chemistry. A feature of the work is the data on the qualitative chemical composition of the fats. Chapters on the hydrolytic cleavage of fat from the standpoint of physical chemistry, by E. Abel, and on the cleavage of fat by enzyms, by S. Fokin, are included.

Concerning the estimation of fat in oil-bearing seeds, F. RUPPEL (*Ztschr. Analyt. Chem., 45 (1906), No. 2, pp. 112–114*).—The modified method proposed consists in extracting the bulk of the fat by treating the finely ground seed for 6 hours with ether, then drying the undissolved residue, grinding with quartz sand, and extracting aliquot portions until all fat is removed.

Contribution to the examination of butter, M. SIEGFELD (*Milchw. Zentbl., 2 (1906), No. 4, pp. 145–164, dgms. 5*).—This is a continuation of investigations previously noted (E. S. R., 17, p. 9).

The data obtained in the examination of the butter from 2 dairies for several years are used as the basis for a discussion of the relative value of determinations of the Reichert-Meissl number, Polenske number, saponification number, iodin number, and the average molecular weight of the fatty acids in the examination of butter. In general, an increase in the Reichert-Meissl number was accompanied by an increase in the saponification number and a decrease in the iodin number, and in the average molecular weight of the nonvolatile fatty acids. The sample having the lowest Reichert-Meissl number, 23.7, had a saponification number of 218.7, an iodin number of 47.4, and an average molecular weight of 269.9. The sample having the highest Reichert-Meissl number, 31.65, had a saponification number of 229.9, an iodin number of 34.6, and an average molecular weight of 257.6.

A simple method of determining fat in milk, KÜTTNER and ULRICH (*Ztschr. Öffentl. Chem., 12 (1906), No. 9, pp. 162–166*).—Numerous tests were made of the Sichler method in comparison with other methods, the results being considered as showing that this method is a decided improvement over the rapid methods previously used.

Gerber's salt method, C. BEGER (*Milchw. Zentbl., 2 (1906), No. 3, pp. 120–123*).—The author reports favorably upon the use of this new method of determining fat in milk.

The influence of acetic acid and alcohol in gravimetric determinations of the total solids in milk, A. SEGIN (*Milchw. Zentbl., 2 (1906), No. 3, pp. 115–119*).—The author uses the covers of porcelain crucibles from which the small central handles have been broken off, measuring into each cover about 2.5 cc. of milk, and rapidly weighing the sample. The milk is then evaporated over a water bath and the residue dried to a constant weight in a water oven at 100° C., which requires about 4 hours. No absorbent material is used.

The time required for drying to a constant weight was increased by the addition of acetic acid and alcohol and higher results were usually secured. The direct drying in small porcelain dishes is recommended as one of the most accurate, convenient, and reliable methods for determining solids in milk.

On the watering of wine and milk, L. SURRE (*Ann. Chim. Analyt., 11 (1906), No. 5, pp. 163–165*).—The methods given for the detection of added water depend upon the diphenylamin reaction for nitrates, which is not given by these materials when pure.

Collaborative work on tannin analysis, F. H. SMALL (*Jour. Soc. Chem. Indus., 25 (1906), No. 7, pp. 296–298*).—This is a brief review of the work of several associations on the methods of estimating tannin. A fairly satisfactory method, the principles of which are given, has resulted, according to the author, from this collaborative work. The various lines of work of the American Leather Chemists' Association now in progress are outlined.

Miscellaneous chemical analyses made in 1901, A. M. PETER and L. O. BEATTY (*Kentucky Sta. Rpt. 1901, pp. 263–295*).—Analyses are reported of 49 samples of sorghum juice, 22 of butter, 27 of sugar beets, 17 of soils, 7 of feeding stuffs, 9 of common salt, 4 of crude petroleum, 1 of marl, 2 of phosphate rock, 4 of clay, 4 of ashes, 2 of tobacco stems, 1 of a tobacco by-product, 5 of tobacco extract, 3 of Paris green, 1 of a commercial substance recommended for use in curing tobacco, 5 of Kentucky asphalt rock, 1 of iron ore, and 24 of mineral waters. Determinations were also made of the arsenic in 6 samples of sprayed cabbage.

Miscellaneous chemical analyses made in 1902, A. M. PETER, L. O. BEATTY, and S. D. AVERITT (*Kentucky Sta. Rpt. 1902, pp. 283–335*).—Analyses are reported of 16 samples of sorghum juice, 31 of sugar beets, 10 of butter, 27 of soils, 1 of old wood ashes, 61 of grasses and forage plants, 6 of soy beans, 1 of mushrooms, 2 of cotton-seed meal, 1 of a calf food, 1 of distillers' corn bran, 1 of dried distillers' grains, 5 of distillery slop, 5 of clay, 2 of niter earth, 1 of dissolved bone, 1 of agricultural lime, 1 of cow manure, and 42 of mineral waters.

Miscellaneous analyses, C. H. JONES and F. M. HOLLISTER (*Vermont Sta. Rpt. 1905, pp. 339, 340*).—Analyses of a number of miscellaneous materials, including nitrate of soda, dried blood, tankage, bone (raw and steamed), acid phosphate, muriate of potash, wood ashes, muck, and mixed fertilizers, are reported.

METEOROLOGY—WATER.

Monthly Weather Review (*Mo. Weather Rev., 34 (1906), Nos. 1, pp. 1–60, figs. 19, charts 8; 2, pp. 61–108, figs. 9, charts 28*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of January and February, 1906, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 1.—The Cyclonic Storm of October 6–12, 1905, in the North Atlantic Ocean (illus.), by J. Page; Improved Methods for Finding Altitude and Azimuth, Geo-

graphical Position, and the Variation of the Compass—Second Article (illus.); Studies on the Thermodynamics of the Atmosphere—I, Asymmetric Cyclones and Anticyclones in Europe and America (illus.), by F. H. Bigelow; Atmospheric Electricity, by G. C. Simpson; Atmospheric Electricity in High Latitudes, by G. C. Simpson; The Time of Moonrise and Moonset (illus.), by W. F. Rigge; A Possible Extension of the Period of Weather Forecasts, by E. B. Garriott (see p. 1045); Forecasts and Verifications in Western Australia, by W. E. Cooke; The Relation of Forests to Rainfall (illus.), by W. F. Hubbard (see p. 1044); An Important Old Local Weather Record for Philadelphia, Pa.; An Appeal for an Aero-physical Observatory in Japan, by S. T. Tamura; Tornadoes—Hailstones—Thunderclouds, by J. P. Gibson; and Weather Bureau Men as Educators.

No. 2.—The Relation between Storm Movement and Pressure Distribution (illus.), by E. H. Bowie; Climatology of Haiti in the Eighteenth Century (illus.), by C. F. Talman; Mean Annual Rain Map of New South Wales; Studies on the Thermodynamics of the Atmosphere—II, Coordination of the Velocity, Temperature, and Pressure in the Cyclones and Anticyclones of Europe and North America (illus.), by F. H. Bigelow; Vertical Air Currents, by F. W. Proctor; Snow Formed by Mixture of Warm and Cold Air, by R. W. Gray; Prevention of Damage by Frost, by R. P. Skinner (see p. 1044); Early Knowledge of the Tides at Panama, by R. A. Harris; Publication of River Gage Readings; Weather Bureau Men as Educators; Life and Work of James P. Espy; Lectures on Meteorology; Hailstorms in the Bahamas; A Fake Rain Maker; and Outline for the Study of Meteorology in the New York State Normal School.

Meteorological observations (*Idaho Sta. Rpt. 1905, pp. 36–48*).—Daily and monthly summaries are given of observations during 1905 on temperature, pressure, precipitation, cloudiness, and wind movement. The mean temperature of the year was 48.6°, the highest temperature 103°, July 22; the lowest −13°, February 11; the total precipitation (rainfall and melted snow) was 20.37 in., the rainfall being 17.51 in.

Meteorological summaries for the year 1901 (*Kentucky Sta. Rpt. 1901, pp. 296–301*).—Tabular summaries for 1901 are given of observations at the station on pressure, temperature, precipitation, cloudiness, wind movement, and casual phenomena.

Meteorological summaries for the year 1902 (*Kentucky Sta. Rpt. 1902, pp. 336–341*).—Tabular summaries for 1902 are given of observations at the station on pressure, temperature, precipitation, cloudiness, wind movement, and casual phenomena.

Meteorological observations (*Maine Sta. Bul. 124, pp. 229–231*).—Monthly and annual summaries are given of observations at the experiment station on pressure, temperature, precipitation, cloudiness, wind movement, and of rainfall at 24 different places in the State. The mean pressure for the year was 29.84 in., the mean temperature 42.13° (normal for 37 years 42.2°), precipitation 32.01 in. (normal for 37 years 43.98 in.), snowfall 70.5 in. (normal for 37 years 91.6 in), number of clear days 150, cloudy days 121.

"The winter of 1904–5 was one of unusual severity, December being 4½°, January 3°, and February 4° below the average for these months. . . . During this same period the thermometer registered zero or below, as the minimum temperature, on no less than 50 days.

"For three successive years the total precipitation has been very low, the deficit for the past year amounting to about 12 in., or over one-fourth of the whole. The shortage was especially noticeable in March and October, in which months the precipitation was about one-fifth the average. In but one month of the year, November, did the precipitation equal the average amount."

Meteorological observations, J. E. OSTRANDER and T. A. BARRY (*Massachusetts Sta. Met. Buls. 207, 208, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1906. The data are briefly discussed in a general note on the weather of each month.

Meteorological observations at the Michigan Agricultural College for the year 1904 (*Michigan Sta. Rpt. 1905, pp. 99–123*).—Tabulated daily and monthly summaries of observations during 1904 on temperature, pressure, precipitation, humidity, cloudiness, wind movement, etc.

Swedish meteorological observations, 1904, H. E. HAMBURG (*Met Iakttag. Sverige* [*Observ. Mét. Suéd.*], *K. Svenska Vetensk. Akad., 46* (*1904*), *pp. X+157*).—This report is divided into 3 parts, (1) daily observations at 18 stations of the second order, (2) monthly and annual summaries of all the meteorological elements furnished by 39 stations of the second order, and (3) 5-day means of temperature at the 39 stations included in part 2.

Meteorological observations for the year 1904 at the Ploti Agricultural Experiment Station, M. SVOLINSKY (*Ghodichnuĭ Otchet Ploty. Selsk. Khoz. Opuitn. Stantziĭ, 10* (*1904*), *pp. 1–25*).—As in previous years (E. S. R., 16, p. 544), this report summarizes observations on precipitation (including snowfall), evaporation, humidity of the air, temperature of the air and of the soil at different depths, insolation and solar radiation, atmospheric pressure, and direction of wind. The total precipitation during the year was 299.4 mm., the smallest for the ten years during which observations have been made at the station. The distribution of the rainfall, however, was favorable for the growth of crops. The mean annual temperature of the air was below normal. The maximum temperature was 35 1° C., July 18; the minimum, —23.2°, January 11 and 13. The maximum pressure during the year was 764.6 mm., the minimum 728 mm. The prevailing direction of wind was northwest.

Observations at the meteorological observatory of the University of Innsbruck in 1902, W. TRABERT (*Ber. Naturw. Med. Ver. Innsbruck, 29* (*1903–4, 1904–5*), *pp. 277–337*).—Detailed tabular records of daily observations on atmospheric pressure, temperature, humidity, cloudiness, wind, and precipitation, and hourly observations with self-recording apparatus on pressure, temperature, humidity, rainfall, and sunshine are given for each month of the year.

International Meteorological Conference at Innsbruck (*Nature* [*London*], *72* (*1905*), *Nos. 1873, pp. 510–512; 1875, pp. 562, 563; 73* (*1906*), *No. 1892, pp. 331, 332*).—A summary account of proceedings of this conference held at Innsbruck September 9–15, 1905, under the presidency of J. M. Pernter.

In his opening address the president discussed particularly the importance and progress of exploration of the upper air and the problem of weather periods and their connection with and dependence on the activity of the sun. Among the subjects receiving particular attention were investigations of excessive rainfall, solar radiation, long series homogeneous observations, meteorological observations during the last century, island meteorological stations, and use of wireless telegraphy to announce the approach of storms.

Japanese meteorological service in Korea and China, S. T. TAMURA (*Science, n. ser., 23* (*1906*), *No. 584, pp. 396, 397*).—The organization of a series of stations under the supervision of the Chemulpo Meteorological Observatory and their equipment are briefly described.

Climatic notes on the Sahara, E. F. GAUTIER (*Ann. Géogr., 14* (*1905*), *No. 78, pp. 459–461; Bul. Amer. Geogr. Soc., 38* (*1906*), *No. 1, pp. 32–34; abs. in Science, n. ser., 23* (*1906*), *No. 588, p. 555*).—The more important climatic facts brought out in this report are that strictly desert conditions are not as extensive in the Sahara as is generally believed; and that there have been three epochs in the climatic history

of the region, the first marked by conditions which supported a dense population (of the neolithic period), the second by desert conditions, and the third, or present period, in which the land is gradually assuming a steppe-like character.

The gradual desiccation of the region advanced from the Soudan, but to-day the rainbelt is again extending more and more toward the north. On the steppes, where the Soudan merges into the Sahara, the annual rainfall is 6 to 12 inches and supports considerable vegetable and animal life.

Texas rainfall during 1905 (*Texas Farm and Ranch, 25 (1906), No. 10, p. 3, fig. 1*).—A map with brief notes furnished by E. E. Spencer, director of the Texas section of the Weather Bureau, is given. The average annual precipitation for the State as determined from reports of 87 stations was 44.49 in., or 12.55 in. above the normal. The greatest annual precipitation was 86.32 in. at Jefferson, the least 17.8 in. at El Paso. The heaviest rainfall occurred over the eastern, northeastern, central, and coast regions of the State.

Rainfall in the agricultural districts, G. G. BOND (*Queensland Agr. Jour., 16 (1906), No. 5, p. 380*).—A table is given which shows the total rainfall for each month from December, 1904, to December, 1905, inclusive, in 41 agricultural districts of Queensland.

The relation of forests to rainfall, W. F. HUBBARD (*Mo. Weather Rev., 34 (1906), No. 1, pp. 24-26, figs. 2*).—The distribution of forests as dependent upon rainfall is illustrated by conditions in California, and it is shown that "topography and winds are the controlling factors in the distribution of forests. They make most of the Pacific coast a region of winter rains and summer droughts, and, away from the coast, limit the forests to the higher altitudes. . . . As rainfall determines the presence or absence of forests, so the configuration of the land and its relation to water bodies and constant winds determine the rainfall."

Forests and rainfall in Silesia, J. SCHUBERT (*Ztschr. Forst u. Jagdw., 37 (1905), No. 6, pp. 375-380, figs. 3; abs. in Met. Ztschr., 22 (1905), No. 12, pp. 566-570, figs. 3, and Science, n. ser., 23 (1906), No. 589, p. 593*).—This subject is discussed on the basis of the rainfall map published by Hellmann in 1899, the conclusion reached being that forests seem to produce an increase in precipitation. This is ascribed to the fact that forests retard wind movement and promote rise and cooling of the air. If one-half of the observed difference is set down as being due to the increased protection of the gauges set up in or near the forests, the actual effect of the trees themselves would roughly correspond to an increase in altitude of 40 meters.

Prevention of damage by frost, R. P. SKINNER (*Mo. Weather Rev., 34 (1906), No. 2, pp. 79, 80*).—Tests of various smudges and the use of potash salts as fertilizers are reported, which, while not conclusive, indicate that more or less protection may be afforded in some cases by such means.

Cloud studies, A. W. CLAYDEN (*London: John Murray, 1905, pp. XIII+184, pls. 61; rev. in Nature [London], 73 (1906), No. 1896, pp. 416, 417, figs. 2*).—In his review of this book Prof. H. H. Hildebrandsson states that it will be a standard work for all students of clouds. The author accepts the types of the International Cloud Atlas and arranges his various forms as subforms of these types with the exception of the nimbus cloud, which he classifies as a subform of the stratus type.

On cloud formation in the Alpine valleys.—Contributions to the mechanism of cloud formation, H. VON FICKER (*Ber. Naturw. Med. Ver. Innsbruck, 29 (1903-4, 1904-5), pp. 193-275*).—A series of observations at various elevations to study especially the formation of stratus clouds in inland valleys is reported.

Apparatus for observing and recording storms (*Sci. XX. Siècle, 1905, Aug. 15, Sup.; abs. in Rev. Sci. [Paris], 5. ser., 5 (1906), No. 9, pp. 278, 279*).—An apparatus devised by A. Turpain, of the meteorological observatory of Puy-de-Dôme for photographically and automatically recording the electrical condition of the atmosphere during storms is described.

A possible extension of the period of weather forecasts, E. B. GARRIOTT (*Mo. Weather Rev., 34 (1906), No. 1, pp. 22, 23*).—A study of counterbalancing tendencies with regard to weather abnormalities in different parts of the globe leads to the conclusion that with completion of daily telegraphic communication with the dominating "centers of atmospheric action" over Siberia, the Alaskan coast, the Azores, and Iceland, "daily available forecasts can undoubtedly be made of the general character of the weather for at least one week in advance. Such general forecasts could specify the character, whether warm or cold, wet or dry, of the weather of the near future, and could indicate the duration and termination, days in advance, of periods of abnormal weather."

Public water supply of Ohio (*Ann. Rpt. Bd. Health Ohio, 19 (1904), pp. 61–343*).—Reports are given on plans for water supplies or sewerage proposed during 1904 for a large number of places in Ohio.

The results of laboratory examination of waters, sewage, and sewage effluents, and studies of methods of purification are also reported in detail.

It is stated that "with but few exceptions the surface waters of the State are unsuited for a public supply. In many regions the ground water is inadequate for a city of much size. The purification of surface waters must receive more and more attention. A filtration plant must be properly constructed and efficiently operated to afford a safe water supply."

It is suggested that "it would seem not improper for the State Board of Health to collect the evidence to show that the water supply of any city is dangerous to life and health. The attorney-general might present this evidence to a court of competent jurisdiction—to the supreme court, if possible. If satisfied that conditions were such that public interests warranted and demanded it, this court should have authority to compel the city to make necessary improvements within a reasonable time."

Seventy-one cities and 177 villages, representing 55 per cent of the population of Ohio, had a public water supply in 1904.

The sources of water supply in Wisconsin, W. G. KIRCHOFFER (*Bul. Univ. Wis., No. 106, pp. 163–267; abs. in Engin. News, 55 (1906), No. 13, pp. 355, 356*).—It is stated that of the 270 cities and villages in Wisconsin 120 are provided with a public water supply. Fifty of the latter use artesian water, 30 ground water, 14 lake water, 12 river water, and of the remainder the source of supply is not definitely known. Of the artesian well supplies, 27 are from Potsdam sandstone, 10 from St. Peters sandstone, and the remainder from both.

As regards the amount of water used from the various sources, lake waters rank first, artesian waters second, ground waters third, and river waters fourth. As to sufficiency or quantity, lake waters rank first, river waters second, artesian waters third, and ground waters fourth, and as to purity, artesian waters rank first, lake waters second, ground waters third, and river waters fourth. The most serious troubles with artesian waters were hardness and presence of iron.

The biology of water bacteria, E. KOHN (*Centbl. Bakt. [etc.], 2. Abt., 15 (1906), Nos. 22–23, pp. 690–708, figs. 3; 25, pp. 777–786*).—This article reports studies on the general course of multiplication of micro-organisms and changes in the composition of the bacterial flora when water is allowed to stand and the food requirements of a series of saprophytic fresh-water micro-organisms.

The bacterial flora was found to change quantitatively and in composition when large samples of sweet water were allowed to stand for a long time. The increase in germination was greatest in vessels of the kinds of glasses which were the most soluble in water. The phosphorus thus dissolved from the glass was sufficient for the requirements of the organisms. The organisms were found to vary widely with regard to their behavior toward the nutrient solutions, particularly the concentration of grape

sugar and ammonium sulphate solutions supplied. Three per cent grape-sugar solution was found to be too strong for *Urobacillus pasteuri.*

Experiments with copper-iron sulphate for water purification at Marietta, Ohio (*Engin. Rec., 53 (1906), No. 12, pp. 392-394, figs. 4*).—The successful use of a mixture of copper and iron sulphates precipitated with caustic lime and held on the filter for precipitation of impurities and reduction of the number of bacteria in water is reported.

SOILS—FERTILIZERS.

Soils, T. DIETRICH and F. HONCAMP (*Jahresber. Agr. Chem., 3. ser., 7 (1904), pp. 25-99*).—A review is given of the literature relating to this subject published during 1904, classified as follows: Rocks, stones, and their weathering products; cultivated soils, including analyses of soils, physics of soils and absorption, and the lower organisms of soils; and moors and moor culture.

Mechanical analysis of soils, J. A. MURRAY (*Chem. News, 93 (1906), No. 2409, pp. 40-42; abs. in Analyst, 31 (1906), No. 361, pp. 129, 130*).—This article describes "a long tube sedimentation process."

The apparatus employed consisted of an Erlenmeyer flask (of about 200 cc. capacity) of which the neck, after removal of the flange, was exactly the same diameter as a long glass tube which was attached to it by means of a piece of india-rubber tubing fitted outside of the tube and of the neck of the flask. The tube actually used was 147 cm. long by 2.3 cm. internal diameter. "A wide shallow glass basin about 20 cm. diameter and a few small porcelain evaporating dishes about 7.5 cm. diameter are also necessary. . . .

"The experiment was carried out as follows: Five gm. of the air-dried fine soil (i. e., that which had passed through 100-mesh sieve), thoroughly disintegrated in dilute ammonia solution, was put into the flask, which was then vigorously shaken, filled nearly full of water, and attached to the tube. Water was then poured gently down the side of the tube (so as not to disturb the sediment in the flask) till it also was full, when the open end was closed with a cork, and the whole inverted over the large basin of water. The cork closing the end was immediately withdrawn, and one of the small porcelain evaporating dishes, previously dried and weighed, placed beneath the open end of the tube.

"The sediment began to descend whenever the tube was inverted, and the first particles were deposited in the dish in about fifteen seconds. After a short interval this dish, containing the first portion, was removed and replaced by another, and this again by a third, and so on. These dishes containing the several fractions of the sediment thus removed from the large basin were of course full of water, of which, however, a considerable part was separated by simple decantation, after standing for a few minutes, and the remainder driven off on the water bath. The dried residue was then weighed, and examined under the microscope for determination of the size of the particles."

Results of tests of the method on a sample of stiff clay soil and of Rothamsted soil are reported.

It was found advisable in case of the heavier soil to make a preliminary rough separation of the finer and coarser material by shaking with weak ammonia, allowing to stand 15 minutes, and pouring off the solution containing the fine material in suspension. The coarser material was introduced into the apparatus described and separated into 3 fractions, viz, those separating in 5, 15, and 40 minutes after the beginning of the test. Preliminary separation was not necessary in case of the lighter Rothamsted soil.

A chemical study of some Oregon beaver-dam soils, C. E. BRADLEY (*Jour. Amer. Chem. Soc., 28 (1906), No. 1, pp. 64, 65*).—Analyses of 5 samples of beaver-dam

soils of the Willamette Valley, one of which is virgin and the others have been used for a number of years in onion growing, are reported.

These soils when virgin are composed largely of organic matter of a peaty nature. They are porous, light, and loose, with no tendency to bake or form lumps. The analyses show that their nitrogen content is large. Potash is present in liberal quantities, but is of low availability. Phosphoric acid is not deficient and is largely in available form. The soils contain sufficient lime to keep them sweet, and lime is always in excess of magnesia.

The nitrogen content of the virgin soil was 1.56 per cent and varied from 0.78 to 2.06 per cent in 3 of the cultivated soils. The total potash content was 0.14 per cent in the virgin soil and varied from 0.1 to 0.28 per cent in the other soils. The phosphoric-acid content was 0.26 per cent in the virgin soil, varying from 0.21 to 2.3 per cent in the cultivated soils. The availability of the potash and phosphoric acid was determined by digestion in 0.5 per cent hydrochloric acid.

Report on the soils of Dorset, with suggestions on manuring, cultivation, etc., J. PERCIVAL (*Univ. Col. Reading, Agr. Dept., Ann. Rpt. Soils Dorset, 7 (1905), pp. 50, map 1*).—This report summarizes in a simple manner the more practical results of the analyses of 100 samples of soil from various parts of Dorsetshire which have been previously reported (E. S. R., 15, p. 857), the information being adapted especially to those engaged in farming in Dorset.

"The first part of the report contains general information as to manures. In this part will be found a description of some of the chief kinds of manures and suggestions as to the use of manures for various crops. Some notes on grass mixtures are also given. The second part of the report contains a description of the various kinds of soils in the county according to their geological formations; and suggestions are given on points connected with the manuring and cultivation of each class of soil, largely based upon the analyses of typical soils, of which a list (with the results) is given for each district."

A geological map is given which makes it possible to locate the different classes of soils discussed. It is shown that a large proportion of the area consists mainly of chalk formation, while another large area is occupied by a series of sands of low fertility. The chief deficiency of the chalk soils seems to be potash.

On loess soils and loess marls, HALENKE, KLING, and ENGELS (*Vrtljschr. Bayer. Landw. Rat., 10 (1905), No. 3, pp. 447–455*).—This article describes the various types of loess occurring in the Rhenish Palatinate and discusses their origin and transformations, especially their changes in lime content. Examinations of a large number of samples show a variation of 0.08 to 6.05 per cent of lime in the surface soil and 0.19 to 47 per cent in the subsoil, ranging from pure sandy loess to loess marl. The chemical and physical make-up of the latter is considered in detail.

The fertilizer requirements of Hessian soils, E. HASELHOFF (*Das Düngungsbedürfnis der hessischen Böden, pp. 39; Fühling's Landw. Ztg., 55 (1906), No. 3, pp. 73–81*).—The composition and fertilizer requirements, as determined by pot experiments, of Hessian soils of different geological origins are discussed.

The soils tested were of basalt, bunter-sandstein, shell lime, graywacke, and clay slate types. The composition of the different soils and of the rocks from which they were originally derived is given. All of the soils responded to applications of nitrogen. Their behavior toward potash was variable, depending upon their origin and content of available potash as shown by analysis. The basalt, shell lime, and clay slate soils were benefited by applications of phosphoric acid, the graywacke soils did not respond to such applications, and bunter-sandstein soils varied in their behavior toward phosphoric acid according to the amounts of available phosphoric acid present as shown by analysis. Only the basalt soils showed a need of lime. It was concluded that pot experiments are a reliable means of determining the fertilizer requirements of soils.

The effect of plant growth and of manures upon the retention of bases by the soil, A. D. HALL and N. H. J. MILLER (*Proc. Roy. Soc. [London], Ser. B, 77 (1905), No. B514, pp. 1–32, figs. 2; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 520, II, pp. 119, 120*).—The investigations reported in this article deal "with the changes in the amount of calcium carbonate, the chief substance in the soil acting as a base, which are brought about by natural agencies, by manuring, and particularly by the growth of plants."

It is stated that the Rothamsted soils generally contain about 3 per cent of calcium carbonate, due mainly to former applications of chalk. "Determinations made in numerous samples from different plats of Broadbalk, Agdell, and Hoos fields, taken at different dates from 1856 to the present time, show that the soils of the unmanured plats lose in drainage on the average about 1,000 lbs. of calcium carbonate per acre per annum. This agrees closely with results derived from analyses of field drainage by Creydt, von Seelhorst, and Wilms [E. S. R., 13, p. 723; 16, p. 856].

"The loss of calcium carbonate is increased when ammonium salts are employed by an amount equivalent to the acid of the manure. Sodium nitrate and farmyard manure diminish the loss.

"Analyses of wheat plants grown in water culture and of the solutions themselves showed that the plants take up an excess of acid from the salts supplied, leaving behind a corresponding excess of base. This explains how it is that, despite losses by nitrification, soils which contain only minute amounts of calcium carbonate (examples of such soils are given) are able to maintain a neutral condition. The experiments also furnished evidence that the roots of the plants did not excrete any organic acid or other organic matter.

"Finally it is shown that calcium oxalate and other organic salts are converted into carbonate by soil organisms."

Investigations on changes in the nitrogen of soils, F. LÖHNIS (*Mitt. Landw. Inst. Leipzig, 1905, No. 7, pp. 1–105; Centbl. Bakt. [etc.], 2. Abt., 15 (1905), Nos. 12, pp. 361–365; 13–14, pp. 430–435; abs. in Jour. Chem. Soc. [London], 88 (1905), No. 518, II, p. 854; 90 (1906), No. 519, II, p. 46*).—The investigations here reported were made on soil of a plat on the Oberholz experimental field of the agricultural institute of the University of Leipzig during 1903 and 1904.

Oats were grown on the plat in 1903, and after these were harvested half of the area was given shallow cultivation while the other was left in stubble. In 1904 the field was planted in potatoes, which received applications of the various fertilizers (bone meal, lime nitrogen, urea, ammonium sulphate, sodium nitrate, etc.), the transformations of which it was the purpose of the experiments to study, namely, the formation of ammonia from bone meal, lime nitrogen, and urea; the formation of nitrate from ammonium sulphate; the liberation of nitrogen from nitrate, and the fixation of nitrogen by bacteria. The influence of the time of year (temperature), weather, and of various methods of culture on the yields and utilization of the nitrogen of the different fertilizers was also studied, and the different kinds of bacteria which took part in the transformation of the nitrogen were isolated and determined.

Decomposition was least affected by the season of the year in case of bone meal and most in case of urea and calcium cyanamid. The nitrogen of calcium cyanamid was quickly converted into ammonia during April and May, and its effect on the crop was similar to that of ammonium salts. It was found that *Bacillus mycoides* converted 39 per cent and *Bacterium vulgare* 28 per cent of the total nitrogen of bone into ammonia in 3 weeks. Allowing the soil to remain in stubble had a distinct effect on denitrification and nitrogen assimilation, but not on the other changes.

The chief effect of bringing the lower layers of the soil to the surface was to diminish nitrification, the least effect being observed in the case of decomposition of bone meal and urea, while there was no effect as regards nitrogen assimilation and decomposition of calcium cyanamid. Dry weather in July was especially injurious as

regards nitrification, nitrogen assimilation, and the decomposition of calcium cyanamid, but was practically without effect on denitrification and decomposition of bone meal and urea. It is concluded that water to the extent of from 60 to 80 per cent of the water-holding capacity of the soil is required for the uninterrupted progress of the various changes in the nitrogen of the soil.

In these investigations soil extracts were used as a culture medium with good results. These extracts were prepared by boiling 1 kg. of soil for 2 hours with 2 liters of tap water. The solution, evaporated to a volume of about 800 cc., was cleared up with talc and filtered, and the filtrate was evaporated until it contained about 0.4 per cent of inorganic constituents. In this way 1 kg. of soil gave as a rule about 600 cc. of neutral extract containing 0.4 per cent of inorganic and 0.6 per cent of organic constituents. The nitrogen content was about 0.02 per cent and the solution was almost entirely free of phosphoric acid. Except in the case of the experiments with bone meal, therefore, about 0.5 per cent of dipotassium phosphate was added. In the experiments reported this extract was inoculated with soil, using the latter at the rate of 10 gm. of soil to 100 cc. of solution.

Report of the chemical laboratory of the Ploti Agricultural Experiment Station, B. M. Welbel (*Ghodichnuĭ Otchet Ploty. Selsk. Khoz. Opuitn. Stantziĭ, 10 (1904), pp. 75–120; abs. in Centbl. Agr. Chem., 35 (1906), No. 2, pp. 73–76*).—A continuation and extension of previous work (E. S. R., 16, p. 552) on atmospheric precipitation, lysimeter observations, and experiments in vegetation boxes is reported.

The report deals with studies of the adaptability of lysimeters to the investigation of questions relating to the balance of water and nitrogen in the soil as influenced by variations in precipitation, methods of culture, manuring, etc. Three groups of lysimeters installed at the station and the kind of investigations for which they are used are described. It has been found that the method of construction and of filling the lysimeters has a most important bearing upon the results obtained.

Special attention has been given in the experiments with the lysimeters to a comparison of the influence of black fallow and green fallow on the water and nitrogen content of the soil. Black fallow as practiced in these experiments consisted of cultivating the soil and allowing it to lie idle until the following fall. Green fallow consisted in allowing the land to lie without cultivation from one summer to the next. More water accumulated in the lower layers of the black fallow soil than in those of the green fallow, the reverse being true for the upper layers of the soil, but in the latter case the differences were very small.

The drainage was greater in case of the black fallow than in case of the green. There was a greater accumulation of nitrates and greater loss in drainage in the black fallow than in the green. The losses in the drainage were, however, more than made good by nitrogen compounds brought down from the air, aggregating 4.5 kg. of nitrogen per hectare annually. During three years of observation the application of barnyard manure increased the production of nitrates (nitric nitrogen) in the soil 120 kg. per hectare. During the same period soil bearing alfalfa produced 50.22 kg. of nitric nitrogen more per hectare than soil not bearing alfalfa.

Some field notes on soil inoculation, H. N. Starnes (*Georgia Sta. Bul. 71, pp. 91–105, pls. 12*).—The present status of knowledge regarding soil inoculation for legumes is briefly reviewed and experiments with commercial cultures of nitrogen-fixing bacteria on cowpeas grown in an isolated field of typical red-clay land in a low state of fertility are reported.

The experiments were made on fertilized and unfertilized areas of this soil. The results do not indicate any particular advantage from inoculation. "In yield of vines an increase appears per acre of 175 lbs., or about 3 per cent, in favor of the untreated over the inoculated plats, while in the yield of peas the difference is reversed, there being apparent an increase of 35 lbs. per acre, or something less than 5 per cent, in favor of the inoculated plats."

The conclusion is reached "(1) that few soils throughout middle Georgia are likely to be found not already thoroughly colonized or inoculated with the special form of *Pseudomonas radicicola* which uses the cowpea as its host. (2) Consequently, whether the commercially distributed 'cotton-dried' nitro-culture for the cowpea does or does not contain living colonies of this bacterium, it is valueless here."

Observations on a series of introduced leguminous plants indicate that the cowpea organism, which is everywhere abundant in the soils of the station farm, is capable of inoculating leguminous plants of widely differing species. Among the unusual plants so tested and found to develop root tubercles when grown for the first time on the station farm were green gram (*Phaseolus viridissimus*), Newman bean (*P. mungo*), *P. radiatus*, *P. aconitifolius*, and *P. angustissimus*.

"Now, the bacteria forming these tubercles were derived either from the soil itself (that is, from the universally disseminated cowpea bacteria) or were conveyed by the planted seed. The latter hypothesis, though possible, is unlikely, especially since desiccation has been proven so extremely fatal to *P. radicicola*. Had the seed been sterilized before planting it would have, of course, determined the matter; but the plat was merely a variety test of certain Phaseoli, with no reference to its bearing upon soil inoculation. In either case it seems to indicate that our soil is not dependent upon artificial inoculation."

Soil inoculation for legumes from artificial cultures by the help of bacteria, C. D. Woods and J. M. Bartlett (*Maine Sta. Bul. 126, pp. 28-30*).—Negative results in inoculation experiments with peas, clover, and alfalfa on a number of farms in different parts of Maine during the season of 1905 are reported. The cultures used for inoculation were obtained from this Department and from a commercial concern. The farmers of the State are cautioned not to depend upon such cultures, but in case of attempts to raise leguminous crops not commonly grown in the region to inoculate their land with soil from fields on which the crops have been grown.

An experiment with Moore's cultures of nitrogen-fixing bacteria, V. Peglion (*Staz. Sper. Agr. Ital., 38 (1905), No. 9, pp. 769-784, pls. 4*).—The results of experiments with medic, lupines, sulla, and white clover on virgin and cultivated soils indicate as a rule that Moore's cultures were very active in producing root tubercles and in increasing growth in soils which had not already been inoculated by natural means; but the writer points out that such conditions are exceptional in localities where legumes of various kinds have been grown for centuries, and hence the cultures have only a limited usefulness in practice and should not be expected to take the place to any extent of good cultivation and the application of mineral fertilizers to promote the growth of legumes.

Nitrification of the organic matter applied to the soil in form of sewage, G. Masoni (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 2 (1905), No. 3, pp. 196-208*).—This is an account of a continuation of previous experiments by the author and relates particularly to the relation of moisture to denitrification.

The experiments here briefly reported lead to the conclusion that liquid sewage from cesspools is not only capable of rapidly nitrifying when applied to the soil, but also aids nitrification in the soil itself. Loss of nitrogen from the soil during hot dry summer weather may be checked by applications of sewage.

Recent experiments in the nitrogen-enrichment of soils, F. T. Shutt and A. T. Charron (*Separate from Proc. and Trans. Roy. Soc. Canada, 2. ser., 11 (1905), Sec. III, pp. 53-64*).—This paper (1) presents the results of certain recent researches that demonstrate the extent and rapidity of the depletion of soil nitrogen under what is evidently an irrational method of farming, and (2) brings forward data to show the value of the legumes, especially clover, as a means of maintaining and increasing fertility through the addition of nitrogen and humus. The discussion is based upon field and laboratory studies made by the authors at the Canadian Experimental Farms.

A new nitrogenous manure, J. HENDRICK (*Trans. Highland and Agr. Soc. Scot., 5. ser., 18 (1906), pp. 75-77*).—Field experiments on oats and barley with lime nitrogen as compared with nitrate of soda and sulphate of ammonia are briefly reported. The results show that the lime nitrogen was but slightly inferior to nitrate of soda or sulphate of ammonia. "In no case did any injury appear to be caused to the germination of oats or barley by using the cyanamid at the rate of 1 cwt. per acre along with the seed."

The conversion of atmospheric nitrogen into nitric acid, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 11 (1906), No. 8, pp. 233-235*).—This article briefly reviews investigations on this subject and describes the various methods which have been proposed for fixing the nitrogen of the air, particularly that of Birkeland and Eyde.

Chemistry and the world's food, R. K. DUNCAN (*Harper's Mo. Mag., 112 (1906), No. 671, pp. 720-731*).—A popular review of progress in investigations relating to the utilization of the nitrogen of the air for industrial purposes, especially as a fertilizer.

Nitrogen requirements of crops, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 11 (1906), No. 7, pp. 201-203*).—The demands of crops on the nitrogen of the air and the soil are briefly discussed.

It is estimated that the crops produced on the 24,000,000 hectares (9,716,575 acres) of land under cultivation in France remove about 273,000 metric tons more of nitrogen, 149,000 tons more of phosphoric acid, and 377,000 tons more of potash than is returned to the soil by farm manures. The most economical means of making up this deficit are discussed.

Fertilizers, E. HASELHOFF (*Jahresber. Agr. Chem., 3. ser., 7 (1904), pp. 100-229*).—A review is given of the literature relating to this subject published during 1904, classified as follows: Analyses of fertilizers and preservation of manure, results and methods of fertilizer control, and fertilizer experiments.

Commercial fertilizers, G. ROBERTS (*California Sta. Bul. 171, pp. 29, figs. 3*).—The results of fertilizer inspection during the year ended June 30, 1905, are reported, including analyses of 151 samples of fertilizers and notes on valuation, mechanical condition of fertilizers, etc., and the text of the fertilizer law.

Commercial fertilizers, G. ROBERTS (*California Sta. Bul. 173, pp. 26*).—This bulletin gives the results of fertilizer inspection during the six months ended December 31, 1905, including analyses of 138 samples of fertilizers and a list of brands of fertilizers and fertilizing materials offered for sale by the registered manufacturers and dealers in the State.

Fertilizer inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 127, pp. 47-64*).—This bulletin contains the analyses of manufacturers' samples of brands of fertilizers licensed before February, 1906, with explanations regarding constituents of fertilizers and valuation.

Commercial fertilizers, J. L. HILLS and C. H. JONES (*Vermont Sta. Bul. 121, pp. 81-104*).—This is the first bulletin issued in connection with the fertilizer inspection for 1906 and gives results of analyses of 56 brands. A table is also included showing the composition of 126 brands on sale in the State during the past 5 years. The character and contents of the more important previous bulletins of the station on fertilizers are explained and notes are given on valuation.

Commercial fertilizers, J. H. STEWART and B. H. HITE (*West Virginia Sta. Bul. 97, pp. CIII-CVII+108-170*).—This is the complete report of the work of fertilizer inspection in West Virginia during 1905, including analyses of 238 samples.

Commercial fertilizers, M. S. MCDOWELL (*Ann. Rpt. Penn. Dept. Agr., 10 (1904), pp. 135-155*).—This is a general discussion of the sources, nature, and uses of the various commercial supplies of nitrogen, phosphoric acid, and potash.

Artificial fertilizers, their functions and use, F. E. LEE (*Jour. Dept. Agr. Victoria, 3 (1905), No. 10, pp. 713-725, fig. 1*).—This article summarizes information

regarding the source, nature, and use of fertilizers, giving also suggestions regarding the mixing of fertilizers and a discussion of methods of valuation.

The fertilizer industry (*Tradesman, 54 (1906), No. 9, pp. 98, 99*).—Data are given for 10 southern States, showing 162 fertilizer establishments with an invested capital of $29,966,685 and a value of product of $18,921,591.

Mineral resources of the United States, calendar year 1904, D. T. DAY (*U. S. Geol. Survey, 1905, pp. 1264, pls. 2*).—The principal information of agricultural interest in this report has already been noted from another source (E. S. R., 17, p. 451).

Fertilizer trials at the Royal Agricultural Academy of Sweden, 1903–4, H. G. SÖDERBAUM (*K. Landtbr. Akad. Handl. och Tidskr., 44 (1905), No. 4–5, pp. 289–311, fig. 1*).—*On the after effects of different kinds of phosphatic fertilizers.*—This is a report of an investigation conducted since 1901, in which the effects of the following phosphatic materials have been studied: Superphosphate, dicalcium phosphate, tricalcium phosphate, precipitated phosphate, and bone meal. Different varieties of oats were grown in vegetation pots each year, and after the first year applications of sodium nitrate and potassium sulphate, with or without addition of calcium carbonate, were made each year.

The highest aggregate yields of oats for the four-year series were obtained from the applications of superphosphate and of dicalcium phosphate, and the action of these fertilizers appeared to be independent of whether or not lime had been added. The effect of both tricalcium phosphate and bone meal was reduced by nearly one-half during the four years by the addition of lime, and the superiority of the former over the latter in the case of the limed pots, and of bone meal over the tricalcium phosphate in the case of the pots receiving no lime, gradually disappeared, so that the total results for the entire series were practically the same. The action of bone meal (with no lime) was found to be decidedly inferior to superphosphate even after the fourth year.

The fertilizer value of Algerian phosphate and apatite compared with that of other phosphatic materials.—The trials were made in 10-in. glass cylinders, with oats grown in a sandy soil, and with peas grown in a marsh soil. In the former trials Algerian phosphate produced an increase of only 3.3 to 5.3 per cent over the cylinders receiving no phosphoric acid, the increase obtained in the case of superphosphate being placed at 100, and the increase in the case of the fine-ground apatite amounted to 0.4 to 1 per cent, according to the quantity of phosphoric acid added (50 to 150 kg. per hectare). In the latter trials with peas on marsh soil the effect of the sifted Algerian phosphate was about 57 per cent of that of superphosphate for peas alone, and 63.7 per cent for the entire crop (peas and vines). The corresponding figures obtained for apatite were 3.9 per cent and —1.4 per cent.

Culture trials to determine in how far the effect of phosphatic fertilizers depends on the character of the simultaneous nitrogenous fertilization.—It has been found in earlier investigations that the effect of superphosphate or dicalcium phosphate was not influenced by the kinds of nitrogenous fertilizer applied, but that the tricalcium phosphate and bone meal produced appreciably larger crops when mixed nitrogenous fertilizers were applied than when sodium nitrate only was added with the phosphates.

This subject was studied further by the author during the years 1902 to 1904. In pot experiments with Ligowo oats, in which different phosphatic materials were added with either nitrate of soda or nitrate of ammonia, the results obtained with superphosphate or Thomas phosphate were higher in the case of applications of nitrate of soda than when corresponding amounts of ammonium nitrate were applied, while the opposite held true with Algerian phosphate and with bone meal. The effect of applications of different nitrogenous fertilizers in connection with bone meal

was next studied, also for Ligowo oats, with the result that a marked increase in yields was obtained with ammonium sulphate.

The next highest results were secured in the case of fertilization with ammonium sulphate and sodium nitrate, while sodium nitrate alone with bone meal gave the lowest results, this effect being equally marked both in the yield of total crop and of grain. Liquid manure or albumen with sodium nitrate gave somewhat lower results than sodium nitrate and ammonium sulphate. The effect of the phosphatic fertilizers applied is, therefore, shown to depend to a large extent on the character of the nitrogenous fertilizers applied or present in the soil.

Culture trials with nitrogenous and phosphatic fertilization in increasing amounts.—These trials were planned to study the methods of pot experimentation. They were conducted in glass cylinders, 29 cm. deep by 24 cm. in diameter, filled with 28½ kg. of a sandy soil, low in nitrogen (0.011 per cent) and phosphoric acid (0.04 per cent phosphoric acid soluble in hot hydrochloric acid, sp. gr. 1.15), the crop grown being oats.

In the first series, in addition to a basic fertilization of fine-ground marble, superphosphate, and potassium sulphate, with a slight addition of magnesium sulphate and salt, sodium nitrate was added to different cylinders in amounts ranging from 1.5 to 6 gm. per cylinder (50 to 200 kg. per hectare). Increasing nitrogenous fertilizations in all cases produced an increase in the crops harvested, the increase being largest with the smallest amounts of nitrate applied and smallest with the heaviest applications, so that the increase obtained beyond applications of 150 kg. per hectare (134 lbs. per acre) may be considered within the limits of experimental error.

Both the weights of kernels and of straw increased with increasing applications of nitrate. The ratio of straw to kernels was narrowest in the case of the largest amounts applied, up to 125 kg. per hectare, when a small widening of the ratio began to appear. It was found, in general, that a fertilization of 150 kg. per hectare (= 0.026 gm. per kilogram of soil) produced an optimum development of the crop, and that the crop produced on a fertilization of 50 kg. of nitrate by its appearance gave decided evidence of a lack of proper nitrogenous fertilization.

In the second series the trials were conducted under similar conditions as in the case of the preceding series; 0.71 to 5.71 gm. of superphosphate (corresponding to 25 to 200 kg. per hectare) were added to sets of 3 cylinders each. The increase in the oat crop harvested from the different cylinders was less regular in this than in the preceding series. The highest increase was obtained between 25 and 50 kg.; between 75 and 125 kg. only a small increase in yield was secured, while at 150 kg. a marked increase again occurred, the maximum crop being obtained at 175 kg. Between 175 and 200 kg. a decrease in yield occurred. The optimum results evidently lay between 75 and 150 kg., and may be placed at 0.017 gm. per kilogram of soil for the soil experimented with and under the conditions of these trials.—F. W. WOLL.

On the factors which influence the fertilizing value of the phosphoric acid of bone meal, H. G. SÖDERBAUM (*Landw. Vers. Stat.*, *63* (*1905*), *No. 3-4*, *pp. 247-262*).—Experiments in glass cylinders 50 cm. high and 25 cm. in diameter carried out with oats during 1902 and 1903 are reported. (See also the preceding abstract.) They included comparative tests of superphosphate, dicalcium phosphate, tricalcium phosphate, Thomas slag, Algerian phosphate, apatite, and bone meal alone or combined in various ways with sodium nitrate, ammonium nitrate, ammonium sulphate, and other nitrogenous fertilizers (some organic), the object of the combination being to determine the influence of the different nitrogen compounds on the availability of the phosphoric acid of the phosphates, as has also been done by Prianishnikov (E. S. R., 17, p. 538).

The results show that the bone meal in presence of ammonium salts, as well as of organic nitrogen compounds, gave larger yields than when used in connection with

nitrate of soda alone. Similar results were obtained with Algerian phosphate and precipitated tricalcium phosphate. An increase of yield was produced by mixtures of nitrates and ammonium salts as well as by ammonium salts alone, the maximum increase occurring in case of the latter. The yield of grain was, as a rule, increased more than that of straw, the greatest increase of straw being, as a rule, with applications of organic nitrogen compounds. The increase due to applications of ammonium salts varied widely from year to year with the weather conditions.

Under favorable conditions the total yield was more than doubled, the yield of grain nearly tripled by the bone meal. In case of superphosphate, Thomas slag, and precipitated dicalcium phosphate there was no such increase of yield following the application of ammonium salts. In fact, in some cases there was a decided decrease in yield. When lime was not present in large amounts the bone meal in combination with ammonium salts was fully as effective as superphosphate.

Methods of using untreated rock phosphate, E. T. MEHARRY (*Ill. Agr., 10 (1906), No. 5, pp. 173–177*).—This is a summary of experiments by the Maryland, Ohio, and Illinois stations on the fertilizing value of untreated rock phosphate.

Manurial value of molasses residue as compared with ammonium sulphate and 40 per cent potassium salts, LILIENTHAL (*Illus. Landw. Ztg., 25 (1905), No. 34, pp. 319, 320; abs. in Jour. Chem. Soc. [London], 88 (1905), No. 516, II, p. 650*).—The dried molasses residue used in the comparative tests here reported contained 3.5 per cent of nitrogen and 13 per cent of potash, but no phosphoric acid. The residue produced about the same yield of potatoes as the mixture of ammonium sulphate and 40 per cent potash salt, with which it was compared. The quality of the potatoes produced was good.

The development of the potash industry, H. PRECHT (*Ztschr. Angew. Chem., 19 (1906), No. 1, pp. 1–7*).—A brief review of the history and present status of this industry.

German potassium deposits, W. SCHMIDTMANN (*Amer. Fert., 23 (1905), No. 6, pp. 22–24*).—A brief explanation of the formation of these deposits is given, and a doubt is expressed as to whether like deposits of equal strength and purity exist in any other country.

The use of lime in agriculture, D. A. GILCHRIST (*Jour. Bd. Agr. [London], 12 (1905), No. 7, pp. 400–406; Trinidad Bot. Dept. Bul. Misc. Inform., 1906, No. 49, pp. 18–22*).—A summary of available information regarding sources of supply, methods of application, and action of lime in the soil, considered mainly from the British standpoint.

Corncobs as fertilizers and as fuel (*Industrialist, 32 (1906), No. 17, pp. 270, 271*).—Compiled analyses are reported to show that corncobs have very little value as fertilizer (2 lbs. of nitrogen, 0.4 lb. of phosphoric acid, and 6.8 lbs. of potash, worth $1.36) and less than that of barnyard manure, wheat straw, or corn stalks. They are of more value as fuel ($2 per ton if wood is worth $6), and the resulting ashes are rich in potash (about 50 per cent). The feeding of charred cobs to poultry and hogs for tonic or medicinal purposes is recommended.

Dead leaves as a fertilizer (*Mo. Consular and Trade Rpts. [U. S.], 1905, No. 303, p. 276*).—A brief note is given on a report from the U. S. consul at Nantes on the relative fertilizing value of the leaves of different trees. From the results reported it is concluded that 44 lbs. of pear leaves, 80 lbs. of poplar, 51 lbs. of peach, 83 lbs. of locust, 82 lbs. of elm, and 174 lbs. of vine, respectively, are equal in nitrogen to 100 lbs. of ordinary manure.

Hog bristles as a fertilizer, E. MIÈGE (*Jour. Agr. Prat., n. ser., 11 (1906), No. 5, p. 145*).—This material contains about 9 per cent of nitrogen, which is very slowly available in the soil. The improvement of its availability by treatment with superheated steam, acids, etc., or by composting, is suggested. It is stated that gardeners have used the material with success for destroying slugs.

Bat guano from the Federated Malay States, W. R. DUNSTAN (*Agr. Bul. Straits and Fed. Malay States, 4 (1905), No. 10, pp. 394-397*).—Descriptions and analyses are given of 4 samples of bat guano obtained from caves in different parts of the Malay States. The results show that although these guanos are comparatively rich in phosphoric acid (8.6 to 17.52 per cent), of which a fairly large proportion (3.25 to 9.75 per cent) is soluble in ammonium citrate solution and is therefore in condition to be readily utilized by plants, they are deficient in the very important constituents, potash (0.88 to 2.01 per cent) and nitrogen (0.84 to 2.47 per cent).

Water as a plant food, BACKHAUS (*Chem. Ztg., 29 (1905), No. 80, p. 1067; Fühling's Landw. Ztg., 54 (1905), No. 22, pp. 757-762*).—Observations made on the Berlin sewage farm during the dry season of 1904 on the value of water as a factor of production are briefly reported, and the actual money value of the increase due to the application of 1 cubic meter of water in case of oats, wheat, hemp, and grasses is calculated. The latter varied from 1.35 cts. in the case of grass to 2.57 cts. in the case of oats.

The conditions necessary to the fullest and most economical use of water in plant production are also discussed, including increasing rainfall by forest planting, storage of water and construction of other irrigation works, deep culture, increasing humus content of the soil, controlling the water content and evaporation, choice of cultivated plants, tillage, etc.

FIELD CROPS.

The breeding of agricultural plants, C. FRUWIRTH (*Die Züchtung der landwirtschaftlichen Kulturpflanzen. Berlin: Paul Parey, 1905, pp. XVI + 201, figs. 25*).—Previous volumes of this work have already been noted (E. S. R., 16, p. 1065). This volume, the third of the series, treats of breeding potatoes, Jerusalem artichokes, flax, hemp, tobacco, hops, and leguminous forage plants, including clovers. Thirty different species are discussed and notes on the blossoming period, pollination, selection, correlation, variation, hybridization, and seed culture are given. A bibliography of 54 references, including books, bulletins, and periodicals, is listed.

Report of work at McNeill Branch Experiment Station for 1904, E. B. FERRIS (*Mississippi Sta. Bul. 87, pp. 7-16*).—In a corn fertilizer test the same quantities of nitrogen and phosphoric acid gave practically the same yields when given as cotton-seed meal and acid phosphate, cotton-seed meal and reverted acid phosphate, or raw ground bone. The cotton-seed meal was applied at the rate of 84 lbs., the acid phosphate 232 lbs., the reverted acid phosphate 414 lbs., and the raw ground bone 166 lbs. per acre. In a variety test with corn, Cocke Prolific and Eureka headed the list with yields of 51.6 and 51.5 bu. per acre, respectively.

In a fertilizer test with cotton 126 lbs. per acre each of acid phosphate and cotton-seed meal gave 700 lbs. of seed cotton; 165 lbs. of ground bone, 780 lbs. of cotton; and 168 lbs. of cotton-seed meal and 70 lbs. of acid phosphate, 710 lbs. of cotton per acre. Nearly all other applications gave much lower yields. Among the different varieties tested Allen Long Staple stood first in the production of seed cotton. The average of plats with the rows 4 ft. apart gave 742 lbs. of seed cotton per acre, which was considerably better than was obtained from narrower plantings.

Cowpeas grown as a second crop matured after the rainy season was over and made good hay. It is stated that peas planted early in the season have very little tendency to make fruit, while those planted the latter part of June or in July are likely to fruit heavily. A large and profitable crop of sweet potatoes was grown, the leading variety being Dooly Yam.

In work with sugar cane 420 gal. of first-class sirup was secured on one-half acre of plant cane. Immature tops of cane and tops with only one mature joint were used for planting, but were found unsatisfactory. It is estimated that the yield of

cassava roots secured at the station was at the rate of 15,000 lbs. per acre. Few crops are believed to equal it in tonnage on the sandy soils on which it was tested.

Deep preparation for corn, with shallow cultivation, gave better results than other methods of treatment, while with cotton deep preparation and deep cultivation gave practically the same yield as deep preparation and shallow cultivation. The deep preparation of the land consisted of subsoiling to a depth of 18 in. during the spring of 1903 and plowed to a depth of 5 in. during the spring of 1904, while for shallow preparation the ground was broken 5 in. deep during both seasons.

An inoculated plat of vetch grew to be waist high and was very strong and vigorous, while an uninoculated plat gave very poor results. Notes are also given on rape and Bermuda grass which were grown at the station.

Report of field work done at the [Mississippi] station for 1904, W. R. PERKINS (*Mississippi Sta. Bul. 88, pp. 13*).—Among 10 varieties of short staple cotton the highest total value per acre, $49.02, was produced by Cook Improved. The production of the least remunerative variety, Berry Big Boll, was equal in value to $26.59. John Bull, a long staple cotton, and Cook Long Staple produced values equal to $52.78 and $52 per acre, respectively. It is pointed out that the growing of long staple cotton is not always the most profitable. The different varieties here tested are briefly described.

Ten varieties of corn were tested and among them Hick Improved Marlboro stood first with a yield of 55.8 bu. per acre, followed by Columbian White Mammoth with 52.3 bu. The yields of soy bean hay from 4 varieties ranged from 3,880 to 6,148 lbs. per acre. Yields of Johnson grass hay on 3 different plats varied from 3.75 tons per acre to 5.91 tons. From an average fertilizer application of 87½ lbs. of cotton-seed meal and 100 lbs. of nitrate of soda a profit of $4.93 per acre was secured in growing Johnson grass hay. The experience of the station in growing alfalfa has been that crab grass is likely to kill out the alfalfa plants.

The comparative value of oats, cowpeas, and corn for the production of forage was studied. The value of corn fodder per acre amounted to $14.14, of cowpea hay to $14.63, and of oats and cowpea hay to $16.11.

Report on field crops at the Sugar Experiment Station, Audubon Park, New Orleans (*Louisiana Stas. Rpt. 1905, pp. 3–9, figs. 2*).—It is reported that seedling canes D. 74 and D. 95 have maintained the high standard of previous years. This season D. 74 tasseled in several places in the State as well as in Florida, and it is hoped that seedlings originating in Louisiana may be produced. Promising results secured in tests with cane loaders and harvesters are reported, and it is stated in this connection that D. 74, standing erect and withstanding storms far better than the native canes, presents less difficulty to harvesting with machinery.

Among notes on various crops grown at the station it is reported that maximum yields of 3,162 lbs. of seed cotton and 3,140 lbs. of cured alfalfa hay per acre were secured.

Cereal investigations (*Kansas Sta. Rpt. 1905, pp. 20–26*).—A description is given of cooperative experiments with the Bureau of Plant Industry of this Department in the testing of newly introduced varieties, and of hybrids and selections of cereal crops.

The work is carried on at McPherson and Fort Hays. Many of the results secured have already been noted (E. S. R., 17, p. 129). The yields of the different varieties of cereal crops grown in 1904 are tabulated and the extent of the plantings for 1905 is outlined. The weather conditions and the growth of the various crops during the season are discussed and the rainfall for the year beginning July 1, 1904, is recorded.

The prevention of lodging in cereals (*Rev. Gén. Agron., 15 (1906), No. 1, pp. 18–21*).—The lodging of cereals is discussed and a method of preventing it described. It was found that on very rich soil by mowing luxuriantly growing grain when 30

cm. high, removing the upper 15 cm., and leaving the cut material as it falls will not only prevent lodging but will also make a more uniform crop in length of straw and size of head and kernel. If after the first cutting the growth of the crop is vigorous enough to indicate danger of lodging, it may be cut again about 2 weeks later when the plants have again reached the height of 30 cm. The mowing should be done when the dew is off, preferably in the afternoon. This method was successfully applied in 1901 on Chevalier barley growing on rich and well-fertilized soil during a warm, rainy season.

Prout's farm, an example of 45 years' continuous culture of cereals without manure, B. Skalweit (*Mitt. Deut. Landw. Gesell., 21 (1906), No. 8, Sup. 8, pp. 13–16*).—The general management of the farm, the crop rotations followed, the use of commercial fertilizers, the cost of production, and the value of the crops produced are briefly discussed.

Report on experiments carried out at Bramford and Saxmundham by the East Suffolk Education Committee, T. H. Middleton (*Cambridge Univ., Dept. Agr., 1904, pp. 48, dgm. 1*).—A rotation experiment was conducted to study the effects of different kinds of plant food on common crops. The crops grown in the rotation were roots, barley, clover or beans, and wheat. The fertilizers used were nitrate of soda, superphosphate of lime, and muriate of potash.

The importance and value of these three fertilizers varied with the soil and the crop. On clay soil nitrate of soda was of great value to mangels and of some value to barley; superphosphate, to clover, mangels, and barley, while potash had little or no effect. On light soil nitrate of soda benefited mangels and barley, and muriate of potash mangels and clover; but superphosphate did not benefit any of the crops. The continuous use for 12 years of 2 cwt. of nitrate of soda per acre on the light soil did not deteriorate the land, while a similar use of superphosphate was injurious to mangels and apparently, to a slight extent, to some of the other crops. The continued use of barnyard manure for 12 years on this light soil did not result in any appreciable accumulation of fertility.

In the second rotation experiment the quantities of manures to be used, the time of their application, and their effect were studied. The best results were secured by using 1 cwt. of nitrate of soda and 5 cwt. of superphosphate of lime per acre for the root crop, 2½ cwt. of superphosphate for barley, the same quantity the following season for clover, and 10 tons of barnyard manure for the wheat crop. The experiment further showed that residues of fertilizer applications may have substantial values, varying, however, with the crop. Clover extracted more from residues than barley and barley more than roots. It was shown that clover may receive great benefit from superphosphate applied a year before the crop is sown, while mangels appear to be benefited very little by the same treatment. It was also shown that the residue of any particular application is greatly influenced by the soil. The barnyard manure left a valuable residue on the clay soil and but an unimportant one on the light soil.

The results of experiments on the improvement of poor grass land show that on a clay soil from 5 to 10 cwt. of basic slag per acre is the most profitable application. Potash and lime did not prove profitable. The use of nitrogenous manures in conjunction with phosphates when beginning to improve poor clay soils is not recommended.

A fertilizer experiment with alfalfa showed that on clay soils this crop responds freely to phosphatic manures, remaining indifferent to dressings containing potash, while on sandy soils the potash manures are very effective and phosphates may fail to show improvement.

Variety tests of wheat, oats, and potatoes, G. C. Watson and N. G. Miller (*Pennsylvania Sta. Bul. 76, pp. 13*).—The yields of varieties most productive at the station since 1887 are reported.

Of 20 varieties of winter wheat 9 yielded over 31 bushels per acre. The 3 leading varieties, Harvest King, Martin Amber, and Royal Red Clawson, yielded 34.60, 34.58, and 34.22 bu., respectively. The average yield of all varieties was 29.17 bu. per acre. The average of the 13 smooth varieties was 28.86 bu., and that of the 7 bearded varieties 29.74 bu. Dietz Longberry Red and Reliable gave the heaviest weight of grain per bushel, 61.25 lbs. Of the varieties tested for 15 years Fulcaster stands in the lead with 31.13 bu. of grain and 3,821 lbs. of straw per acre.

The 19 varieties of oats grown in 1905 gave an average yield of 56.09 bu. per acre, the range being from 47.80 to 61.50 bu. Czar of Russia ranked first in the production of grain, and Mortgage Lifter, which stood last in grain production, ranked first in yield of straw. In 1904 White Russian was the leading variety, with 77 bu. of grain per acre, while Czar of Russia yielded only 69.13 bu. The yield of White Russian in 1905 was 56.93 bu. per acre.

Forty-three varieties of potatoes were grown this season and an average yield of 187 bu. per acre was secured, but of this quantity 27.4 bu. were unmerchantable tubers. The leading varieties, mentioned in decreasing order of yield, were Eureka, Heath Medium Late Beauty, Uncle Sam, Early Rose, Early Puritan, Extra Early Crusader, Irish Daisy, Early Nancy, and Bliss Triumph, all producing over 200 bu. of merchantable tubers per acre, while the remaining varieties fell below this yield. The average total yield for all the varieties for 1904 was 77.9 bu. more than the yield for 1905.

Crops of southern France, Algeria, and Tunis, C. Rivière and H. Lecq (*Cultures du midi de l'Algérie et de la Tunisie. Paris: J. B. Baillière & Son, 1906, pp. XII + 511, figs. 69*).—This book discusses the culture of tropical and subtropical crops grown in southern France and in northern Africa. The topics discussed are climate, cereal and garden crops, viticulture, forage crops, forestry, fruits, ornamentals, plants furnishing rubber, tannin, dyes, fibers, perfume, starch, oil, etc., and the marketing of fruits and legumes.

Clark method of growing grass for hay, C. D. Woods and J. M. Bartlett (*Maine Sta. Bul. 126, pp. 25-28*).—About 2 acres of land was treated as nearly as possible in accordance with the Clark method.

The results indicated the value of thorough preparation of the seed bed and liberal applications of fertilizer in grass growing. The grass was sown in the fall of 1904 and in July of the next year 6¼ tons of field-cured hay was harvested. This crop cost about $40 for fertilizers and about $37 for labor and seed. The station does not believe this method adapted to Maine, as it does not fit in with mixed farming and rotation of crops, and further, because the seeding formula recommended does not contain clover.

Report on an experiment conducted at Cransley, Northamptonshire, in seasons 1901, 1902, and 1903: The improvement of poor pastures, T. H. Middleton (*Cambridge Univ., Dept. Agr., 1904, pp. 35, dgms. 2*).—The results of cooperative work indicated that to improve poor pastures on clay soils it is advisable to begin with the use of from 7 to 10 cwt. of basic slag per acre. Barnyard manure, sulphate of ammonia, or dissolved bone should not be used in the beginning, but may be applied after the first few years are over. The improvement of soil by clovers and the management of pastures is discussed.

Range improvement, J. J. Thornber (*Arizona Sta. Rpt. 1905, pp. 17-21*).—The range improvement work of the station for the year ending June 30, 1905, with the weather conditions for the period, is briefly reviewed.

A good growth of forage plants on the range reserve is reported, and the prevailing species are enumerated. Two common species of Indian wheat made the best growth, the average height being 10 in. In estimating the relative amount of spring forage on the mesas on small plats from which the plants were pulled up by the roots, dried, and weighed, it was found that the average yield was at the rate of 2,812 lbs. of forage to the acre.

Notes are given on cultural operations, the continuation of work upon the economic cacti, the forage garden, and on the viability of native grass seeds. The different species of forage plants sown on the range reserve and the percentage of germination as determined for a large number of native grasses are enumerated.

Alfalfa, T. F. HUNT ET AL. (*New York Cornell Sta. Bul. 237, pp. 139–177, figs. 10*).—This bulletin is a report of progress on cooperative tests with alfalfa in several parts of the State and of field tests on the college farm. An outline of cooperative demonstrations in the different branches of agriculture to be made in 1906 is appended.

The location and description of soils suited to alfalfa culture in the State are given, and the results of experiments with the crop are discussed. In 63 per cent of the cooperative tests in districts where alfalfa growing is not yet established no nodules at all were found on the plants. During 2 seasons' work with alfalfa bacteria transported by the cotton method, only one case gave an increase of vigor in the plants, while the method of inoculating by the use of soil from an old alfalfa field uniformly resulted in an abundance of nodules.

Dressings of lime usually proved beneficial, and on the heavier soil of the college farm it was found essential to the crop. The use of 2,000 lbs. per acre produced somewhat better results than 1,000 lbs. and practically as good as 3,000 lbs. The results on the heavy soils indicated that the best success is to be obtained by a combination of lime, stable manure, and inoculation by means of soil from an old alfalfa field. On gravelly loam soil alfalfa without a nurse crop grew much stronger before winter set in than that grown with a nurse crop, but this superiority was not maintained in the season's production. During 3 months' storage thoroughly field-cured alfalfa hay lost between 15 and 16 per cent in weight.

Cooperative experiments with alfalfa, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 126, pp. 35–41*).—Cooperative culture tests with alfalfa in 1904–5 are described and directions given for the culture of the crop. The results thus far secured do not show conclusively that in general alfalfa can be successfully grown in Maine.

Alfalfa and red clover, J. W. WILSON and H. G. SKINNER (*South Dakota Sta. Bul. 94, pp. 16, fig. 1*).—The results of 3 years' experiments with alfalfa and clover at the station and in the forage tests at Highmore are presented.

In the spring of 1904 native sod on the college farm was disked 5 times and part sowed to alfalfa and part to clover, but only the clover made a fair stand. At Highmore a field of Turkestan alfalfa sowed in 1899 still produces good yields. Satisfactory results have been obtained with both the Turkestan and the American varieties. In 1902 a field foul with mustard was sown to alfalfa, with the result that the following year the mustard was practically killed out and a first-class stand of alfalfa was secured.

At the station Turkestan alfalfa sowed May 10, 1903, yielded 5,437 lbs. of hay per acre from 2 cuttings in 1904 and 5,113 lbs. from 2 cuttings in 1905. Montana-grown seed sowed in May, 1903, gave a total yield from 2 cuttings of 5,733 lbs. the following season. The experience in alfalfa culture by farmers throughout the State is briefly noted.

Clover was successfully grown on thoroughly disked native prairie and *Bromus inermis* sod. The seed was sown at the rate of 10 to 12 lbs. per acre and perfect stands were secured. A clover field 1 year old gave a total yield of 5,484 lbs. of hay per acre as compared with 3,294 lbs. on a sod-bound *Bromus inermis* field. In another field a total yield of 9,358 lbs. of hay per acre was secured from clover and only 2,360 lbs. from *Bromus inermis*.

Culture of the fodder beet in Tunis, R. GAGEY (*Bul. Dir. Agr. et Com.* [*Tunis*], *9 (1905), No. 37, pp. 554–560*).—The results of culture experiments with fodder beets are shown in tables.

In selecting a variety or choosing the distance between plants it is recommended that the total quantity of dry matter produced per hectare be taken into account and

not only the percentage. It was found that subsoiling for fodder beets increases the average weight and size of the roots, gives much larger total yields, and decreases the density and the percentage of dry matter, the beets being larger and containing more water. Although the percentage of dry matter is lowered, the total yield is generally increased, especially in dry years. A considerable increase in yield of beets was also secured by irrigation.

Corn culture, R. J. Redding (*Georgia Sta. Bul. 69, pp. 41–60*).—Twenty varieties of corn tested in 1905 gave an average yield of 38 bu. per acre. The leading varieties, Albemarle and Marlboro, yielded 47.36 and 46.20 bu. per acre, respectively.

Residual effects of fertilizers applied to cotton in 1904 were not apparent in the corn crop of 1905. The plants fertilized this year yielded an average of 30.24 bu and those not fertilized since 1904, 25.82 bu. per acre. This increase of 4.44 bu. from the use of fertilizers was secured at a cost of 80 cts. per bushel. A second fertilizer test gave similar results and it is concluded that the use of commercial fertilizers is not a reliable means to permanently increase the productiveness of soils.

Applying one-half of the quantity of cotton-seed meal at planting and one-half on May 19 was found inexpedient. Substituting the equivalent in nitrate of soda for one-half the quantity of cotton-seed meal did not prove profitable. As in previous years, cotton-seed meal was more effective than cotton seed applied directly to corn.

Corn improvement, J. A. Jeffery (*Michigan Sta. Spec. Bul. 34, pp. 23, figs. 15*).—This bulletin is a popular discussion on the improvement of corn by a more careful selection of seed and better cultivation. Directions are given for the selection, storing, and testing of seed corn, and the different cultural operations connected with growing the corn crop. Cross breeding corn for the improvement of quality and the fixation of character are discussed and outlines for judging or scoring corn are given.

Experiment with corn, G. A. Crosthwait (*Idaho Sta. Rpt. 1905, pp. 33–35*) —In 1904 26 varieties secured from various sources were tested and the earliest ears selected for seed. Seed was saved from 9 dent and 2 flint varieties. Only a few ears were secured from each variety making seed, and 5 of those saved were from seed grown near Moscow. In 1905 over 50 varieties were tested and seed selection was made with reference to earliness.

The germination of seed corn, J. W. T. Duvel (*U. S. Dept. Agr., Farmers' Bul. 253, pp. 16, figs. 4*).—The value of making germination tests is pointed out and complete directions for carrying on the work are given. Percentages of germination of seed corn as determined in individual ear tests of 10 kernels each from the crop of 1905 are shown in tables.

Of 67 lots of corn secured from various sources in different States 60 showed an average germination of less than 95 per cent, 48 of less than 90 per cent, and 10 of less than 80 per cent. The average germination of all ears tested was 86 3 per cent. The poorest lot contained only 2 good ears in 50, with 16 dead ears and an average germination of 39.4 per cent. The best 2 lots germinated 97.8 and 97.3 per cent, respectively, the first lot having 41 good ears in 50 and the second 42 in a possible 49. Of the 3,322 ears tested 1,416 germinated 100 per cent. The average germination of the remaining 1906 ears was only 77.7 per cent. This shows a gain of 13.7 per cent by discarding ears of low vitality.

Experiments with cotton and corn in 1905, J. F. Duggar and J. M. Richeson (*Alabama Canebrake Sta. Bul. 23, pp. 29*).—Among the varieties of cotton grown, Russell and Woodfin gave the largest yields on bottom lands and Woodfin and Peterkin on poor upland. On bottom land Russell produced a crop valued at $55.56 per acre for lint and seed. On poor red upland the value of the crop of Woodfin, the leading variety, was $18.31 per acre in lint and seed, with lint at 11 cts. per pound and seed at 70 cts. per 100 lbs. Subsoiling for cotton which was done when the subsoil was too wet gave unfavorable results. In 2 tests plowing 6½ in. deep resulted in the largest crop, but in 2 other tests no advantage from deep plowing was derived.

The yields of corn were but slightly affected by the method of preparing the soil or planting the crop. Plowing under Egyptian clover and subsequently a crop of cowpeas increased the succeeding corn crop 9 bu. per acre. Corn stover, cotton-seed hulls, or tasseling corn plants plowed under showed no very marked advantage, but the benefits from successive applications of cotton-seed hulls and corn stover became greater each year. Tests made on prairie soils showed that vegetable matter rich in nitrogen, such as is afforded by barnyard manure, sweet clover, and cowpeas, is needed for their improvement.

On poor reddish prairie soils both acid phosphate and cotton-seed meal increased the yield of cotton quite profitably, the increase being 66 lbs. of lint per acre with the phosphate and 40 lbs. of lint with the cotton-seed meal. Kainit was found useless in this fertilizer experiment with cotton. Nitrate of soda, cotton seed, cotton-seed meal, and cow manure, at the rate of 44, 434, 100, and 2,704 lbs. per acre, respectively, used separately, were found profitable for cotton on all grades of prairie land. Acid phosphate did not give decisive results on black slough land but on poor reddish prairie soil this substance and slag phosphate were both found highly profitable. On gray prairie land in good condition the use of 800 lbs. of a complete home-mixed fertilizer, or 8 to 10 tons of barnyard manure gave good returns. Acid phosphate and cotton-seed meal were both more effective when applied before planting. The nitrate of soda gave good results when applied at the first or second cultivation of cotton. Manure from cattle fed on cotton-seed meal and hulls, applied in a small amount in the drill in both cotton and corn culture, increased the yield for each ton of manure about 18 per cent in the first crop after the application, 15 per cent in the second, and 9 per cent in the third, the increase aggregating in value in the 3 years from $4.47 to $11.94 per ton of manure.

Fertilizer applications for cotton and oats are suggested.

Cotton culture, R. J. Redding (*Georgia Sta. Bul. 70, pp. 61–90*).—This bulletin is the report for 1905 on cotton experiments in progress at the station (E. S. R., 16, p. 866).

In the variety test of this year Cook Improved, which ranked first among 30 varieties in total value of crop produced, also stood first in earliness. The value of lint and seed produced by the different sorts ranged from $44.68 to $66.11 per acre. Cook Improved produced 533 lbs. of lint per acre and 880 lbs. of seed, and the next ranking variety, Brown No. 1, yielded 488 lbs. of lint and 767 lbs. of seed. These two sorts were followed by Layton Improved, Moss Improved, Southern Wonder, and Toole Improved, mentioned in the decreasing order of total value produced, and all yielding over $57 worth per acre of lint and seed. The average height of the varieties grown was 3.67 ft., the range being from 3.23 ft. for Jones Re-Improved to 4.18 ft. for Lewis Prize. Moss Improved was the latest maturing variety. The best half of the varieties tested showed a tendency to produce a higher percentage of lint, a somewhat heavier boll, smaller seeds, and earlier maturing plants than the less productive half.

The results of 3 years' fertilizer experiments indicate that when nitrogen is given in the form of cotton-seed meal the best yields are obtained by making the entire application before planting. Such an application bedded on about 2 weeks previous to planting was found to induce early fruiting. From 16 to 20 lbs. of nitrate of soda per acre, applied in the furrow with the seed, has given good returns at the station. Substituting for one-half the quantity of cotton-seed meal its equivalent in nitrate of soda and applying the same as late as June 26 proved profitable. In the experience of the station growing cotton and corn simultaneously on the same ground can not be recommended.

The Mallory plan of preparing land for cotton showed no advantages over the ordinary method. The Mallory plan consists in throwing furrows 8 in. deep at half the distance apart of the intended cotton rows, and running deep subsoil furrows

within the furrows so made. This is done in the fall and the following spring alternate furrows are reopened with a shovel plow and the planting and application of fertilizers performed in the usual way.

A comparison of Peruvian guanos with home mixtures for cotton indicated that the same amounts of available phosphoric acid, nitrogen, and potash in the guanos were of equal value with the same elements in the forms of acid phosphate, cotton-seed meal, and muriate of potash. The results of an experiment with cotton-seed meal and crushed cotton seed, indicated that for fertilizing cotton 865 lbs. of cotton-seed meal is the fertilizing equivalent of 2,000 lbs. of crushed cotton seed.

Suggestions and formulas for the use of fertilizers in cotton culture are appended.

Cotton in Egypt, H. Lecomte (*Le coton en Égypte. Paris: A. Challamel, 1905, pp. 162, figs. 28, map 1*).—In discussing the present condition of the cotton industry of Egypt, this book devotes a chapter each to general cotton statistics, the soil, climate, varieties, variations, cultural operations, harvesting and ginning, soil exhaustion and fertilization, the distribution of cotton culture in Egypt together with the production and exportation of the country, and the culture of the crop in the Nile region under irrigation.

Hardy Bermuda grass, J. Fields (*Oklahoma Sta. Bul. 70, pp. 8*).—Experiments at the station have shown that Bermuda grass should be propagated only from the roots and pieces of sod of a sort that has survived severe winters in Oklahoma. The hardy strain growing at the station and elsewhere in Oklahoma quite generally survived the winter of 1905–6. Directions for planting Bermuda sod and its care after planting are given.

Two and one-half acres of thin upland soil were set to Bermuda grass on June 29 and 30, 1905, by sod planting, and on September 25 a yield of 2,584 lbs. of cured hay per acre, free from weeds and crab grass, was secured. The rainfall during this period amounted to 14.13 in. as compared with an average precipitation of 9.62 in. for the same period in previous years. An analysis of this hay made by the station chemist showed that it contained 9.70 per cent of protein and 1.24 per cent of fat.

The preservation and storage of hops, K. von Baur-Breitenfeld (*Pure Products, 2 (1906), No. 3, pp. 145–150*).—Investigations on the storing of hops indicated that hops should be stored in the hop chambers only when perfectly dry and ripe for bagging, and that sulphuring maintains the quality during storage.

The storage rooms should be kept at an even low temperature and perfectly dry. Temperatures from zero to 2 or 3° R. preserve hops better than higher temperatures because they reduce the moisture in the air to a greater extent and retard the oxidation of the hop resin and oil. The lower temperatures also better preserve the flavor of the hops. Hop chambers with direct refrigeration and stagnant air are as effective as those cooled by circulating cold air.

The potato crop, T. H. Middleton (*Cambridge Univ., Dept. Agr. Farmers' Bul. 3, pp. 54*).—Variety tests were conducted in 1903 and 1904 on a light loam soil. The best yields were secured from Dobbie Factor and Findlay Royal Kidney. Sutton Discovery and Findlay Evergood proved the most resistant to disease.

The sprouting of seeds before planting did not appear very useful for ordinary purposes. Planting entire tubers gave better results than the use of cut seed pieces. Tubers weighing 9 or 10 to the pound, or 1½ to 1⅝ in. in size, were most suitable for planting. Seed imported from Scotland produced equally good crops the first and second years, while the third year the crop was much reduced. The second growth induced by weather conditions in 1904 had a very injurious effect on the cooking quality of the potatoes.

The best results on poor light land were secured with a fertilizer application consisting of 1¾ cwt. of sulphate of ammonia, 3½ cwt. of superphosphate, and 1½ cwt. of sulphate of potash. On a light loam soil the best yield was secured where this same application of commercial fertilizers, together with 12 tons of barnyard manure per acre, was used. The barnyard manure alone also gave good results.

Report on experiments with potatoes, 1905, W. BRUCE and J. PORTER (*Edinb. and East of Scot. Col. Agr. Bul. 9, pp. 25, dgm. 1*).—Among 13 varieties of potatoes tested the second time Factor, Pink Blossom, and Up-to-Date were the only ones which yielded a heavy crop of fair quality. Of the medium early varieties King Edward VII was the most productive, being followed by White Blossom and British Queen. Some of the old standard varieties proved of equal value with the best of the new ones.

Sprouting the seed potatoes in boxes before planting increased the yield as well as the size of the tubers. Sprouted seed planted May 5 produced a better crop than unsprouted seed planted April 14.

On sandy soil the use of commercial fertilizers with barnyard manure was profitable, and on one of the test plats a complete commercial fertilizer gave better results than incomplete applications, although sulphate of potash alone gave a satisfactory return. Sulphate of ammonia gave a larger increase in yield than nitrate of soda. For sandy loams the use of 1 cwt. of sulphate of ammonia, 3 cwt. of superphosphate, and 1½ cwt. of sulphate of potash, given with a medium dressing of barnyard manure, is recommended.

Trial of varieties of potatoes, G. E. ADAMS (*Rhode Island Sta. Bul. 111, pp. 61–74*).—The fertilizer formulas used during a period of 7 years in potato experiments are given and the average yields of varieties for the number of years grown are shown in tables.

The range in yield of the 85 varieties under test was from 426 bu. per acre, the 3-year average of the Great Eastern, to 67.7 bu. per acre, the 2-year average of Rival. The total crop of Astonisher, Gem of Aroostook, and Prof. Dr. Maercker showed a maximum variation of only 0.9 of a bushel, yet in the percentage of merchantable tubers there was a variation of 26.4 per cent of the entire crop. A similar relation was observed between Commercial, Early Maine, and German Early Rose, the difference in yield of merchantable tubers in these 3 varieties being equal to 49.9 bu. per acre. In observing the disease resistance of varieties Prof. Julius Kühn showed the greatest immunity from injury by the blights. The selection of early-maturing varieties is considered as apparently the only safe plan to be followed to keep the crop free from blight.

Potatoes were sprayed 4 and 5 times during the season. Sixteen varieties gave an increased yield of over 50 per cent of the total crop as due to the additional spraying. Fifteen varieties showed an increase of from 25 to 50 per cent, 12 yielded from 1 to 25 per cent greater crops, while 8 varieties showed an apparent loss from the last spraying. The plants of the 15 varieties giving the greatest increase in yield remained vigorous and continued to grow from 2 to 3 weeks longer upon the area sprayed 5 times than upon the area sprayed only 4 times. Peerless Junior, State of Maine, Burbank, White Star, and Vermont Golden Coin, sprayed 5 times, retained from 90 to 100 per cent of their foliage for more than 3 weeks after the plants sprayed only 4 times were dead.

Home-mixed fertilizers for potatoes, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 126, pp. 41–44*).—The details of experiments here reported have been previously noted (E. S. R., 16, p. 1073). In 1905 three home-mixed fertilizers were compared with one commercial potato fertilizer and the results, on the whole, were lower with the home-mixed than with the commercial fertilizer. The results are considered as not admitting of conclusive interpretation at the present time.

Ramie and similar crops in India, G. B. DE CARDO (*La ramie et ses analogues aux Indes Anglaises. Paris: A. Challamel, 1906, pp. 123*).—This book is a translation and a résumé of information on the culture and preparation of ramie and other analogous fiber plants in India. The information here given is taken from the Dictionary of the Economic Products of India, by G. Watt, published from 1889 to 1893.

Field observations upon the tolerance of the sugar beet for alkali, G. W. SHAW (*California Sta. Bul. 169, pp. 29, figs. 20*).—Previous work along this line,

described in earlier publications of the station (E. S. R., 8, p. 683; 12, p. 942), is briefly summarized. The later observations here recorded were made by the author at Grand Junction, Colo., in 1900 and at Oxnard, Cal., in 1904.

The investigations in Colorado indicated that in the virgin soils under test the heavy percentage of alkali lies above the fourth foot, and that the excessive amounts found in the upper foot have been brought there from that depth by shallow irrigation and by the upward leaching of the soil due to seepage. The average of 8 soluble salt determinations upon soils producing either good or fair crops of beets shows a percentage of 0.036 of chlorids, 0.004 of carbonates, and 0.087 of sulphates, or a total of 0.127 per cent in the upper foot of these fields. These figures correspond to 1,440 lbs. of chlorids, 160 lbs. of carbonates, and 3,480 lbs. of sulphates, or a total of 5,080 lbs. of soluble salts in the upper acre-foot. The yields of beets ranged from 7.76 tons to 20.98 tons, or an average of 8.45 tons per acre, with an average sugar content of 16.03 per cent and a purity of 81.8.

Soils producing poor crops of beets under the same conditions of cultivation and treatment were found to carry much more chlorid in the top foot than was held in the upper 3 ft. of the soils producing fair crops. These data are regarded as showing that the soluble salt content of the soil is the primary cause of the failure of beets, but it is pointed out that the high percentage of alkali is not uniform throughout the locality, and that by proper selection of soils these difficulties may be avoided.

The strength of the soil solution was determined as based on 20 and 10 per cent of moisture in the soil. It was found that the heavy adobe soil 2 days after irrigation contained from 18 to 20 per cent of water, while several days after irrigation the moisture content had fallen from 8 to 12 per cent and the plants were suffering from lack of water. As shown by the analyses made, the solution in soil with 20 per cent of moisture contained 2.97 per cent of alkali, and with 10 per cent of water in the soil 5.86 per cent. It is pointed out that when the density of a soil solution becomes too great the vitality of the seed is destroyed or, in the case of already growing plants, the passage of water from the soil into the plant is checked.

At Oxnard, Cal., observations were made in fields with a marked unevenness of stand, which frequently characterizes beet fields on alkali soils. The results on all the different fields pointed to the fact that wherever the chlorid content of the soil approached 0.20 per cent beet culture was unsuccessful. It was further shown that the sulphates had a comparatively limited effect on the growth of beets. The effect of the different salts is more clearly brought out in the following table:

The effect of different percentages of soluble salts on the growth of sugar beets.

Condition of beets.	Sulphates.	Carbonates.	Chlorids.	Total salts.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*
No growth	0.4063	0.0092	0.1957	0.6112
Poor	.3602	.0000	.0742	.4344
Fair	.2010	.0044	.0746	.2800
Good	.2629	.0101	.0419	.3149

On this particular field the sugar content of the beets ranged approximately from 17 to 22 per cent.

In certain portions of these fields where good beets were produced, practically all the alkali was found in the top foot of soil, where it could have little or no effect on the more delicate feeding roots of the plant, while on adjacent spots producing no beets the concentration of the alkali was essentially the same in the first and the second foot of soil, bringing it within reach of the fibrous-feeding roots. These results are regarded as indicating that the distribution of the soluble salts within the soil may be a more important factor than the total quantity of alkali present, and

also as explaining why beets fail to grow in certain places although little or no alkali appears near the surface. The failure of plants, even though the seed germinated well and a good stand was originally obtained, is also accounted for by this fact. In these observations fair beets were found growing in soil with an average of 4,000 lbs. of chlorids per acre-foot, and it was noticed that certain individuals have a much greater resistance to alkali than others. It is believed that the success of beet culture in regions with alkali soils depends upon the proper soil selection and the development of a more alkali-resistant beet.

Sugar beets in the San Joaquin Valley, G. W. SHAW (*California Sta. Bul. 176, pp. 27, figs. 11*).—The results of field observations and analyses connected therewith since 1902 are reported.

In 1902 the average results of 9 tests showed a sugar content in the beet of 14.9 per cent and a purity of 83.5, but the average yield was only 4.74 tons per acre. These figures are regarded as showing that the general climate and soil conditions are suitable for the production of high-class sugar beets. The low tonnage was largely due to late planting. A satisfactory yield can be obtained only by early planting, which will allow the plants to make considerable growth before the hot weather of the summer months.

These conclusions were confirmed by results obtained in 1905. It is also stated that, in general, the results will be very unsatisfactory when the beets are grown without irrigation. The failure of the plantings of 1905 was primarily due to late planting and inadequate irrigation, and in a lesser extent to poor soil preparation, poor cultivation, and beet blight. General discussions on the climatic conditions, moisture and sunshine requirements, and on soils and their preparation and cultivation are given, and the results of earlier experiments conducted by the station with sugar beets in southern California are reviewed in an appendix.

Manurial experiments with sugar cane in the Leeward Islands, 1904–5, D. MORRIS (*Imp. Dept. Agr. West Indies, Pamphlet 39, 1906, pp. 51*).—A summary of the results with seedling and other canes at the experiment stations in the Leeward Islands is given.

At Antigua the results showed that the canes B. 156, Sealy Seedling, B. 306, B. 208, D. 74, D. 95, and D. 109 are specially worthy of attention. The ratoons of 6 of these canes also ranked first at the various stations. In St. Kitt's Caledonian Queen and White Transparent gave the best results, while the Barbados seedling canes B. 208 and B. 147 were also satisfactory. The ratoon crop of B. 208 ranked first with a yield of 30 tons of cane and 8,508 lbs. of sugar per acre in the juice.

Relating to the sugar industry in Peru, T. F. SEDGWICK (*Trujillo, Peru: Haya, Verjel & Co., 1905, pp. 78, pls. 11, charts 3*).—This book contains descriptions of the sugar districts and sugar estates in Peru and a review of the methods of sugar-cane culture in that country, together with a brief discussion on the manufacture of cane sugar and the utilization of by-products. Comparative data from different sugar-growing countries are also given. Special reference is made in this work to the sugar estate known as Hacienda Cartavio.

Germination of seeds as affected by nutrient salt solutions, O. KAMBERSKY (*Ztschr. Landw. Versuchsw. Oesterr., 9 (1906), No. 1, pp. 33–43*).—Work along this line by several investigators is reviewed, and results of experiments at the seed control station at Troppau are reported.

Of each of 15 different field crops 400 seeds were soaked for 48 hours in a solution of a mixture of ammonium and potassium nitrate and sodium and ammonium phosphate. For the purpose of a check test the same number of seeds of each crop were soaked in water for the same length of time. When these samples were subjected to a germination test the seeds soaked in the nutrient salt solution did not sprout so quickly and, with the exception of sugar-beet seed, did not show as high a percentage of germination as the seed soaked in water.

The various crops showed different degrees of resistance, which is believed to be partly due to the age of the seed, although it was observable in fresh seed with a weakened vitality. All degrees of vitality were represented in each individual sample, and it is concluded that the weakest seeds lost their power to germinate when soaked in the salt solution, while in the resistant seeds the germination was delayed. It was also found that the parts of the embryo were differently affected, the plumule appearing more resistant than the radicle. Seeds of grains taken from the germinating chamber and transferred to fresh soil continued their growth normally, but were retarded as compared with seeds not treated with the salt solution.

Seed inspection, C. D. Woods and Bessie G. Tower (*Maine Sta. Bul. 125, pp. 26*).—This bulletin contains the text of the Maine laws regulating the sale of seeds, and the results of analyses of samples of seeds collected by the station in 1905 and received from correspondents from 1902 to 1905. A list of weed seeds from the samples tested is given and attention is called to the free analysis of weeds, seeds, fertilizers, and feeds by the station.

HORTICULTURE.

Department of agriculture and horticulture, V. A. Clark (*Arizona Sta. Rpt. 1905, pp. 10-15*).—Attention is called to the intense heat and light in Arizona and the effect of these on plant growth. Shading has been found a specific for many crops which are injured or even killed in the open. Where the summer heat raises the surface soil to so high a temperature as to interfere with root growth mulching has been found a specific remedy. Deep planting of trees has also been practiced successfully to overcome this trouble.

The results secured at the station with a number of fruits and vegetables during the season are briefly stated. Guavas have been successfully grown, both in the open and in shade, and withstand a temperature of 19° F. The McNeal variety of garden pea was less injured by frost than the American Wonder variety. A study is being made of varieties of olives in Arizona. No insect nor fungus pest has been found as yet to attack this crop.

Some alfalfas from Sahara and Arabia promise to surpass the strain commonly raised at the station in growth during the hot months. The yields of 3 varieties of durum wheats in comparison with the Sonora variety are given. In every case the yield was considerably higher, and the straw, though taller, showed less tendency to lodge. It also rusted much less. Pea plants from light-weight seed died as a result of weather conditions a number of days earlier than from heavy seed. It is believed that considerable valuable work can be done along the line of seed selection.

Report of the horticultural department, J. Troop (*Indiana Sta. Rpt. 1905, pp. 19-21*).—An outline of the experimental work of the department during the year, with some of the chief results obtained. In the use of pedigreed strawberry plants the results of a single season's work indicate clearly that "the pedigree theory as applied to strawberry plants has been overdone."

In some fertilizer experiments with tomatoes great differences in the productiveness of individual vines, due to individuality, were observed. In spraying experiments it is found just as essential to spray for the second brood of codling moth as for the first brood. San José scale has been found in 44 counties of the State. A new aphid was discovered during the summer of 1904, which seems to be especially partial to Houghton gooseberry bushes. The aphid is briefly described and has been given the name of *Aphis houghtonensis*.

Fruits and vegetables, E. B. Ferris (*Mississippi Sta. Bul. 87, pp. 2-7*).—An account is given of the commercial culture and marketing of a number of varieties of fruits and vegetables, including potatoes.

The best results with strawberries have been secured with the Klondyke variety. The most effective fertilizer was a mixture made up of 200 lbs. of cotton-seed meal, 400 lbs. of acid phosphate, and 100 lbs. of kainit. The yield with this fertilizer was at the rate of 191.6 crates per acre. These results with berries, as with all the other crops experimented with, showed that the soil is lacking in phosphoric acid. On account of the scarcity of labor and poor shipping conditions the northern limit of successful marketing was Birmingham and Chattanooga. The best shipping package was a 24-qt. ventilated crate. The returns from 275 24-qt. cases netted a little less than $500.

Asparagus was marketed most profitably in Chicago. Twenty ½-bu. boxes gave a net return of $30. When commercial fertilizers were used on cabbage, the increase over unfertilized plats was 223 per cent, and 299 per cent on soil that had been parked with cattle. The normal fertilizer used on this crop was 430 lbs. of cotton-seed meal, 420 lbs. of acid phosphate, and 200 lbs. of kainit. When either the cotton-seed meal or acid phosphate was decreased the crop was lessened, but when the kainit was decreased the yield remained practically the same.

Wardwell Kidney Wax beans averaged 120.8 bu. per acre, and Improved Valentine 121.6 bu., counting 30 lbs. to the bushel. The use of kainit was without effect in increasing the yield of this crop, but both nitrogenous fertilizers and phosphates gave marked increased yields. The unfertilized soil yielded 66 bu. per acre. When fertilized with a mixture containing 209 lbs. of cotton-seed meal, 114 lbs. of dried blood, 455 lbs. of acid phosphate, and 213 lbs. of kainit the yield was 150 bu. per acre. One-half of this fertilizer mixture gave a yield of 121.5 bu. per acre. When the nitrogen was left out of the mixture the yield was 82 bu. per acre. Acid phosphate alone produced a yield of 104.5 bu. per acre. The net returns from shipping 2 acres of beans to northern markets was $173.29. The bushel hamper was a much more desirable package for this crop than the bushel box.

Burbank was the heaviest yielding variety of potato grown, producing 182.5 bu. per acre. Native seed produced but 70.6 bu. per acre, while with at least 5 varieties from other sources the yield was in no instance less than 126.8 bu. per acre. The net returns from 2 acres of potatoes were $112.

A test was made with different sized seed pieces, varying from 1 eye to whole medium sized tubers. The yield with one-eye pieces was 68.9 bu. per acre, and this was gradually increased to 107.9 bu. when whole potatoes the size of a guinea egg were used. Among other vegetables grown were onions, beets, radishes, kohl-rabi, turnips, ruta-bagas, eggplants, and peppers. The only ones profitably marketed were beets, ruta-bagas, and turnips.

Further studies in lettuce culture, W. STUART (*Vermont Sta. Rpt. 1905, pp. 292–296, pl. 1*).—In an earlier report (E. S. R., 17, p. 249), an account was given of an experiment to determine the comparative value of different forms of chemical fertilizers, the relative value of chemical fertilizers and rotted manure, and the relative influence of surface *v.* subwatering for lettuce. In the present instance a report is made on flat-grown *v.* bench-grown plants; and combination indoor and outdoor lettuce culture.

In the first experiment plants were grown in flats until ready for market. The flats were 12 by 16 by 3.5 in. One dozen plants were grown in each. Similar plants were grown in benches at a distance of 8 by 8 in. apart. The bottom of the flats was filled to a depth of 1.5 in. with well-rotted manure. Thirty-four square feet of space were given to each method of culture.

The plants in the flats were ready for market a week in advance of those in the bench. Their average weight was 86 gm., while those in the bench averaged 210 gm. each. The flat-grown plants presented a good appearance and sold for 40 cts. per dozen, while the bench-grown plants commanded but 50 cts. per dozen. From the

standpoint of space, therefore, the returns per square foot were 26 cts. from flat-grown plants and but 10 cts. from bench-grown plants.

The conclusion is drawn that for local market conditions a greater net profit can be made from lettuce planted in flats. The growing of the plants in flats to maturity considerably lessens the labor required, though the lettuce is not so heavy nor so good by close planting as when sufficient space is allowed for development.

In the combination indoor and outdoor lettuce culture, lettuce was started in the greenhouse and transplanted to the open as soon as weather conditions permitted. Good crops were thus secured. The average weight of the plants of a number of different varieties grown for 2 years is tabulated. Iceberg gave the heaviest yield in each of the 2 years. It is believed that seedlings could be grown equally as well in the hotbed as in the greenhouse for this work, and that in the vicinity of the station this method of culture would be very profitable.

Fertilizer experiments in field culture of garden peas (*Maine Sta. Bul. 126, pp. 30–34*).—Garden peas were grown for a cannery on 2 farms. Part of the peas grown was inoculated with pure cultures of nitrogen-fixing bacteria from the Department of Agriculture and from commercial sources. Commercial fertilizer was used on both farms. A severe drought seriously interfered with the experiment.

On one farm the soil was found to be thoroughly inoculated with the nitrogen-collecting bacteria, and the use of pure cultures was without additional benefit. On the other farm which, so far as known had never been planted to peas, some of the plants on the inoculated plats were found to contain tubercles on the roots, but no more than on some of the other plants which were not inoculated.

The cassaba melon (*Pacific Rural Press, 71 (1906), No. 10, p. 148*).—The history of this muskmelon, also known as Winter Pineapple Muskmelon, is given, with an account of its introduction into the United States, and the methods observed by the author in its culture. This is a late melon, suitable for Christmas use, and grown to some extent as a stock food.

Report of culture experiments in 1905 on the sewage fields of Berlin, J. KLAR and O. MENDE (*Gartenflora, 55 (1906), Nos. 2, pp. 35–40; 3, pp. 66–70*).—The results are given of tests in growing large numbers of flowers and vegetables, with brief comments on the various varieties.

Soil sterilization, W. STUART (*Vermont Sta. Rpt. 1905, pp. 297–299*).—A historical account is given of the development of soil sterilization by means of steam and otherwise in this country, with an account of the author's investigations in sterilizing soil in solid beds and subwatered benches.

"Three in. drain tiles were sunk about 10 in. below the surface of the soil. The lines of tile were laid every 16 in., each line being independent of the other and connected with the surface by a vertical section of draintile." When steam was properly connected and turned in the tile at a pressure of 40 to 60 lbs., a bed containing approximately 70 sq. ft. of surface could be heated up to about 210° F. in about 3 hours' time. When the surface soil was well covered with burlap, the heat was maintained at this temperature for a long time, and was entirely effective against nematodes. This method of soil sterilization involves less labor than the usual method of sterilizing in boxes, as there is no handling of soil and the draintiles are far enough below the surface to be out of the way of cultural operations.

A large portion of the bench surface in the greenhouse is fitted for subwatering by means of galvanized iron pans and layers of porous brick. An attempt was made to sterilize the soil in this bench by injecting steam into the pan through the watering tube. The result was unsatisfactory, as too much steam was required. Much of the steam condensed in coming in contact with the cold porous bricks, and it is believed that it would be more economical to employ a sterilization box in the treatment of soil in subwatered benches.

How to use a planting plan, I. G. TABOR (*Gard. Mag. [N. Y.], 3 (1906), No. 3, pp. 146, 147, chart 1*). A complete chart is given for planting a 50 by 100 ft. lot. The plan shows the kind of trees, shrubs, and flowers to plant, just where each one should be planted, and the method of transferring a planting plan to the ground.

Blossoming of fruit trees, L. B. JUDSON (*Idaho Sta. Rpt. 1905, pp. 23–32, charts 3*).—The blossoming season of a large number of varieties of apples in different parts of Idaho in 1904–5 are tabulated, as well as the blossoming season for 12 varieties of pears and 5 varieties of peaches for the season of 1905.

On the winter injury of apple trees, W. STUART (*Vermont Sta. Rpt. 1905, pp. 299, 300, pls. 2*).—A further note is given on the injury to apple trees during the winter of 1903–4, mentioned in an earlier report of the station (E. S. R., 17, p. 249). The winter-injured trees after blossoming and partially leafing out apparently stopped growth and the unfolded leaves shriveled and died. Later in the season many of the trees pushed out into new growth, usually at the base of the scaffold limbs, or somewhat higher up.

Experiments were undertaken to see if the trees would not be benefited by pruning. A number of eight-year-old Rhode Island Greenings were severely pruned back, others less vigorously handled, and some not pruned at all. It was thought that the severe pruning of the trees on which new growths were being pushed out at the base of the limbs would tend to throw the strength of the tree into a few branches, and thereby induce greater growth and a more shapely head. The orchard was not given good cultivation.

The growth made on the differently handled trees is shown in a series of illustrations. "A careful study of this series of photographs affords little evidence that pruning was beneficial." As a result of the investigations, the author recommends that pruning operations be deferred to the latter part of the growing season or the following spring, rather than immediately after such winter injury as noted in the experiment. Severe pruning is inadvisable.

Influence of stock on scion, W. STUART (*Vermont Sta. Rpt. 1905, pp. 300–305*).—In 1899, 5 classes of plums were root grafted on 4 types of stocks. The stocks used were Americana, Wayland, Marianna, and Peach, and the scions were Stoddard of the Americana group, Green Gage of the Domestica group, Chabot of the Japanese group, Milton of the Wild Goose group, and Newman of the Chicasaw group.

The results secured with this combination of stocks and varieties in Maryland have been previously noted (E. S. R., 14, p. 1069). The present report covers the results secured in Vermont from 1900 to 1905. Tabulated results given in the report show that 93 per cent of the varieties on Americana roots lived, 100 per cent on Wayland, 80 per cent on Marianna, and 40 per cent on Peach. The average diameter of the trunk of the trees produced on these different stocks is shown in the table below, the measurements being made at the collar and 1 ft. above the collar:

Trunk growth of varieties of plums on different stocks.

Variety of plum.	Americana.		Wayland.		Marianna.		Peach.	
	Collar.	Foot above.	Collar.	Foot above.	Collar.	Foot above.	Collar.	Foot above.
	Inches.	*Inches.*	*Inches.*	*Inches.*	*Inches.*	*Inches.*	*Inches.*	*Inches.*
Stoddard	2.00	1.75	1.69	1.32	1.69	1.44	....	....
Green Gage	2.38	2.19	2.72	2.56	2.69	2.50	2.50	2.31
Chabot	2.50	2.81	3.19	2.00	2.72	2.53	....	....
Milton	2.41	2.00	2.50	2.22	3.28	3.19	1.03	.88
Newman	3.03	2.69	3.16	2.97	3.03	2.97	2.88	2.75
Average	2.46	2.19	2.65	2.41	2.68	2.53	2.14	1.96

"These measurements show that Stoddard on Americana gives the greatest average diameter of the trunk, with Marianna and Wayland about equal. Green Gage did best on Wayland, with Marianna a close second, Peach and Americana being third and fourth, respectively. Chabot was best on Wayland and second best on Marianna. Milton was far superior on Marianna than on any other, Wayland and Americana occupying second and third places. Newman did well on all stocks, but was slightly superior, in diameter at least, on Wayland, followed by Marianna, Americana, and Peach in the order named. . . . Stated briefly, Americana seems best for Americana; Wayland for the Japanese; Milton for Marianna, with little choice between Wayland and Marianna for the Domestica group, and no marked choice between any of the four stocks for the Chicasaw group."

The influence of Wayland stock on Milton variety is given special mention. On Wayland the Milton grew more or less upright, while on Marianna the head was low, bushy, and spreading. The variety Newman made especially good growth on Peach roots, and it was suspected that roots might have been sent out by the scions. Some of the trees were dug up, but in only one instance was this found to be true, and this exception is not considered of any vital importance.

"A comparison of the root systems showed the Peach to be the deepest rooted and least spreading. Marianna and Wayland possessed numerous spreading and rather shallow lateral roots. Americana, while having a spreading lateral-root system, was not as symmetrically developed as were the two former. In none of them could the root system be said to be much superior to that of Peach stock." Milton on Marianna stock was much more seriously affected by "plum pocket" than when grown on Wayland or Americana. Whether it was due to stock or not could not be told.

Hybrids in their relation to grafting and wines (*Bul. Agr. Algérie et Tunisie, 11 (1905), Nos. 23, pp. 524–530; 24, pp. 550–557*).—The essential part of this article is an address delivered by L. Daniel before the Viticultural Society of Lyons, in which he reviews his work on grafting in the improvement of grapes, and points out its practical application.

It appears that the best French varieties of grapes can not be improved from the standpoint of the fruit by grafting, but may be improved from the standpoint of resistance. The case is different with hybrids, where opportunity for amelioration by grafting is much greater, since not only can the resistance to phylloxera be thus increased, but the crop greatly modified.

Variations produced by grafting seem often to be hereditary in the vine. It may thus happen that many old varieties may be materially modified in time. In order to avoid this, it is recommended that experimental vineyards be established in which the old French varieties of grapes, which have been originated with such great care, may be preserved in their purity.

Variation by grafting, G. BONNIER (*Fermes et Châteaux, 1 (1905), No. 4, pp. 6–8, figs. 5*).—A popular and somewhat extensive review of the work of L. Daniel on grafting between different species of plants, and on the hybrid variations obtained. The review covers the results of the grafting experiments noted more at length in earlier numbers of the *Record*.

Study of the cider apples of Sarthe, P. L. C. CASSARINI and E. POUPARD (*Bul. Mens. Off. Renseig. Agr. [Paris], 5 (1906), No. 2, pp. 157–179*).—A general account is given of the cider regions of Sarthe, and of the varieties of apples used in cider production. The various varieties are described in considerable detail, and a table given showing the vigor and hardiness of different varieties when grown on the various soils of different regions, the yields obtained, quality of fruit and cider made from it, with analyses of the ciders.

Olives and citrus fruits (*Louisiana Stas. Rpt. 1905, pp. 9, 10*).—During the year 1 variety of olive, Pensulina, produced fruit which was successfully pickled. The fruit is of fine flavor and medium size. It is believed that these are the first olives to be grown to maturity and pickled in Louisiana. Citrus hybrids produced by

this Department by crossing *Citrus trifoliata* with sweet oranges have withstood a temperature of 18° F., the coldest weather at the station since they were planted.

Varieties of dates of Tagant and Adrar, R. ARNAUD (*Bul. Agr. Algérie et Tunisie, 12 (1906), No. 3, pp. 60, 61*).—A list is given of the species of dates grown in these regions, the names being given in both French and Arabic, and comments added as to the usefulness of some of the varieties.

Tropical fruits on the Florida Keys, P. J. WEBSTER (*Fla. Agr., 33 (1906), No. 9, pp. 161, 162*).—An account of the methods of culture of the tropical fruits grown on the Florida Keys, including pineapples, avocado, mangoes, sapodillo, bananas, sugar apples, soursop, custard apples, eggfruit, papaw, pomegranate, etc.

Miscellaneous fruit notes, W. STUART (*Vermont Sta. Rpt. 1905, pp. 305–309*).—Tables are given showing the blossoming, leafing out, and ripening periods of plums and cherries for the years 1903 to 1905, inclusive. The data show a close relationship between the time of flowering and the time of fruiting. Recommendations as to the best varieties of plums and cherries are given.

Growing fall bearing strawberries, S. COOPER (*Amer. Agr., 77 (1906), No. 13, p. 429, fig. 1*).—The Pan-American and Autumn varieties of strawberries that bear fruit in the fall are described and methods given for their cultivation. In the case of the Pan-American variety it is stated that by judicious cultivation and systematic removal of the early blossom stems this variety will continue to bear until the green berries are frozen. An illustration is given of the plant in blossom and fruit.

The transportation of fruit in refrigeration, G. H. POWELL (*Cal. Fruit Grower, 33 (1906), Nos. 919, pp. 1, 3; 920, p. 5*).—A paper presented before the American Society of Refrigerating Engineers at its meeting in New York, December 4, 1905, in which the losses that occur in shipping perishable fruits in refrigerator cars are discussed.

Where fruits are shipped from the orchard without first cooling and are from 3 to 10 days in transit, large losses occur, particularly in the top tiers of fruit. The problem to be overcome is to secure refrigeration which will be sufficient to cool down all parts of the car sufficiently to prevent the development of decay, either by improved methods of car refrigeration or by cooling down the fruit before it is placed in the refrigerator car. Coupled with these requirements is the necessity of having the car refrigeration simple so that an ordinary brakeman could manipulate it satisfactorily.

The cocoanut and its relation to the production of cocoanut oil, H. S. WALKER (*Philippine Jour. Sci., 1 (1906), No. 1, pp. 58–81, pls. 10*).—This is a report of an extensive study of cocoanut production from the standpoint of quality and quantity of the oil yielded.

Analyses are given of the seashore and interior soils on which cocoanuts grew successfully, and of nuts picked at varying stages of ripeness, nuts from different localities, and nuts grown on both sandy soils and clay soils. It had been noticed that cocoanut trees growing near the seashore at San Ramon produced much more fruit than trees standing farther inland. Analyses showed the inland soils to be somewhat superior in the elements of fertility to the seashore soils, but were much less permeable.

The following table shows the fertilizing constituents contained in the husk, shell, meat, and milk of cocoanuts:

Analyses of cocoanuts.

Part.	Nitrogen.	Potash.	Phosphoric acid.
	Grams.	*Grams.*	*Grams.*
Husk	1.609	3.915	0.017
Shell	.660	.947	.459
Meat	4.683	2.475	1.740
Milk	1.542	1.313	.171
Total	8.494	8.650	2.387

It is calculated that 1 hectare of land on which 173 trees are growing will produce a total of 7,000 nuts per annum, and that each tree will lose annually 16 leaves, weighing about 3 kg. each. From these data it is calculated that the total annual drain on the soil per hectare from growing cocoanuts is as follows: Nitrogen, 91.12 kg.; potash, 135.37 kg ; and phosphoric acid, 41.38 kg. Based on these data and the analyses of seashore soil it is calculated that the seemingly barren seashore soils on which cocoanut trees are growing so vigorously contain sufficient nitrogen to produce crops for 307 years, sufficient potash for 1,478 years, and phosphoric acid for 677 years, not taking into account the probable inexhaustible supply of plant food constantly coming down in the seepage water from the interior hills. While irrigation and fertilizing may be of considerable value to trees in the interior, on the seashore irrigation would be of value only in dry seasons, and fertilizers would probably be washed away before they could be used by the trees.

The analyses of the nuts at different stages of growth are given in an extensive series of tables. They show that there is no indication of meat or fatty material in the nut until it has reached its maximum size and the shell is completed. With the formation of the shell the milk becomes rather sweet, and a slimy, pulpy mass, having a sweetish taste and comparatively little oil, begins to deposit on the inside, chiefly on the lower half of the nut. Gradually it extends over the whole of the inside of the nut, becoming denser and thicker and increasing in oil content at the expense of the sugar in the milk. This hardening process continues often in ripe nuts for 2 or 3 months after they have been picked from the tree, or until the nut sprouts.

With the appearance of the sprout the fat stored up in the nut is transformed into sugar and other bodies, and the embryo gradually increases in size until it occupies the whole space inside the nut and utilizes all the nourishment contained therein for its growth. In order, therefore, to secure the largest yield of copra and oil, only thoroughly ripe nuts should be used, and the author states that it is often advisable to allow these to stand in a dry place for a few weeks before they are opened. By the use of green nuts it is shown that there may be a loss of almost 50 per cent, while if nuts are stored for more than 3 months there is a loss due to germination, and often before that time nuts which have been cracked or bruised in gathering become rancid.

Analyses of different colored nuts—golden yellow and light green, both of which turn brown at maturity—show practically no difference in composition. The quality of nuts grown on the seashore, contrary to general statements, was not found to be superior to those taken from trees farther inland. Among 1,000 nuts from the seashore, gathered at random, 55 were found in bad condition, while out of the same number, gathered from the interior, only 15 were spoiled. This difference, it was thought, was due to the harder grounds along the seashore and the consequent greater bruising in falling.

Analyses are given of nuts from Davao. One variety was from trees producing large nuts, rather pointed in shape, and the other from trees bearing small, rounder fruit. The percentage of oil in the nuts free from husks was found to be about the same in both cases.

The seed grower, C. JOHNSON (*Marietta, Pa., 1906, pp. 191, pl. 1*).—This book, believed by the author to be the first of its kind published in any country, gives detailed directions for the production of all the different kinds of vegetable and flower seeds commonly grown in the United States. A section is also devoted to bulbs and shrubs. The usual field-crop seeds, such as clover, wheat, etc., are not considered. Suggestions for originating new varieties, forms of contracts made by seed growers with seed dealers, cultural hints for the ordinary garden crops, germination, color, and vitality of seeds, and descriptions of a number of the more prominent varieties of each of the different vegetables are included.

The author states that to a large extent America still depends upon European growers for the best quality of beet, cabbage, carrot, cauliflower, kale, kohl-rabi, leek, parsnip, parsley, radish, turnip, spinach, and onion seeds, and the choicer grades of flower seeds and bulbs. America satisfactorily produces pea, bean, celery, cucumber, lettuce, melon, and certain kinds of onion seeds, as well as all the more usual field-crop seeds. Much the larger amount of flower seed produced in the United States is grown in California.

FORESTRY.

History of the lumber industry in America, J. E. Defebaugh (*Chicago: Amer. Lumbermen, 1906, vol. 1, pp. XIII+559*).—A large amount of material is here brought together relative to the history of the lumber industry since the discovery of America. Twenty-three of the 31 chapters deal with the industry in Canada. In one chapter the forest geography of North America is considered. In the 6 chapters devoted to the industry in the United States one is concerned with the forest resources, one with the public land policy in its relations to lumbering, one to forestry and forest reserves, one to tariff legislation, one to lumber production, and one to foreign trade.

Forestry statics, a handbook for the advanced sylviculturist, H. Martin (*Die Forstliche Statik. Ein Handbuch für leitende und ausführende Forstwirte sowie zum Studium und Unterricht. Berlin: Julius Springer, 1905, pp. XII+361*).—Part 1 of this work deals with the principles and methods of forestry statics, and part 2 with their application. The various chapters of part 1 take up the production of wood volume through accretion, the value and uses of wood, the production and cost of forests, and the net profits. The work is intended for the use of students and teachers.

Handbook of the timber trade, L. Hufnagl (*Handbuch der kaufmännischen Holzverwertung und des Holzhandels. Berlin: Paul Parey, 1905, pp. VIII+318, figs 28*).—This book treats of the different commercial grades of lumber and timbers, the commercial uses of different kinds of timbers, transportation of timber, etc.

Forestry problems in the United States, T. P. Ivy (*Boston: The Archway Bookstore, 1906, pp. 47*).—The author criticises present methods of conducting civil-service examinations for positions in the forestry service, discusses the effect of the Reserve Act of 1891, which he believes has had the result of considerably increasing the price of lumber and forest products, and urges more extensive sylvicultural operations in the East. As a means of broadening our forest administration he suggests a board of forest conservators of at least 7 members. A discussion is also given of the Mississippi River in its relation to forestry.

Future forest trees, A. H. Unwin (*London: T. Fisher Unwin, 1905, pp. 108, pls. 3*).—There are 3 chapters in this book, the first dealing with the German timber imports from the United States and Canada; the second with the general results of planting experiments with American trees in Germany, Austria, Great Britain, and Switzerland, and the third with the sylvicultural characteristics and treatment of the various American species of trees. The purpose of the book is to present in a concise manner the results of European experiments with imported American trees, most of which are ornamental, for the benefit of English forestry.

Forestry division, K. A. Carlson (*Orange River Colony Dept. Agr., Ann. Rpt., 1 (1904–5), pp. 45–123*).—This gives an outline of the forestry work of the division for the year, with an account of the forest reserves, individual plantations, nurseries, revenues, expenditures, etc.

About 2,700 acres are under the control of the forestry division, on 93 of which plantings have been made. The forestry division recommends that candidates be sent by the government to Yale College to take the 2 years' course of forestry. It is believed that forestry conditions in America are more nearly like those in South

Africa than elsewhere. The cost of the course is less than half that of the English course, and it can be completed in 2 instead of 3 years, as in Europe.

About 2,000,000 cu. ft. of timber was imported into the Colony in 1903, while the average yearly importation is about 700,000 cu. ft. It is estimated that the cost of establishing timber areas in the Colony, carried out on the scale of at least 2,000 acres per annum, would be about $50 per acre, spreading over a period of 30 years.

Report forest department of the Madras Presidency for 1904-5 (*Admin. Rpt. Forest Dept. Madras, 1905, pp. 167*).—This is a progress report covering the constitution of the state forests, their management and administration during the year, and financial results. The appendixes contain details regarding the acreage of forest areas in the different districts and circles, lands under settlement, forest tracts protected from fire, the outturn of timber, fuel, and bamboo, revenues derived from different sources, etc.

Notes on the effects of frost on trees at the government nursery, Irene, L. E. TAYLOR (*Transvaal Agr. Jour., 4 (1906), No. 14, pp. 325-329*).—Three methods were employed to protect trees known to be tender to frost during the winter. These were plant shelters, large screens, and covering with Hessian cloth. The plant shelters were the most effective, and were made of rough Eucalypt poles and thin branches. A framework was built of the poles about 6 ft. high, and over this thin branches were laid at intervals of about 1 to 2 in. Although the shelters do not keep out frost, they lessen its severity by preventing radiation, which is the cause of most damage to trees during the winter. The behavior of about 90 species toward frost is mentioned in detail.

Planting white pine in Vermont, L. R. JONES (*Vermont Sta. Bul. 120, pp. 67-80, figs. 7*).—An account is given of forestry conditions in Vermont, with directions for starting a pine forest, either with seeds, natural seedlings or nursery stock, and the after care to be given it.

On the University farms an experimental tree plantation was made some 8 years ago on a dry, sterile, sandy soil, originally covered with pitch pine. The trees planted were black locust, red oak, white birch, chestnut, cottonwood, box elder, European larch, Norway spruce, and white pine, but only locust and white pine have given promise of profitable return. There is some doubt as to whether locust will be able to survive the attacks of borers, but the white pine has proved an unqualified success. White pines that have been planted for 8 years now stand 7-9 ft. high and have made a growth of 2-4 ft. the last 2 summers.

The starting of a forest by sowing seed broadcast is believed to be a hazardous undertaking. Special attention is called to the fact that the year 1904 was a pine-seed year and that there is an abundance of 1-year-old seedlings now in the State, and that these may well be used for forestry purposes. On a small scale the trees may be obtained from nurseries. The estimated cost of producing trees in a nursery is placed at $2 per 1,000. Maple trees can be bought for about half the price of white pine trees, and it is therefore more economical to plant about half and half maple and pine. Pines grow as well as in pure stands, and as soon as they overtop the maples they will kill out most of them. This will occur in about 20 years, and if this natural thinning is not sufficient the maples should be cut out.

The catalpa tree for cross-ties (*Arboriculture, 5 (1906), No. 3, pp. 69-81, figs. 8*).—This is a report of F. I. Brown, as chairman of the Committee on Roadway and Ballast of the Pennsylvania Railway, on the use of the catalpa tree for cross-ties, and is essentially a compilation of information on the value of *Catalpa speciosa* for lumber, posts, ties, etc.

The value of cultivated rubber to the manufacturer (*Trop. Agr. and Mag. Ceylon Agr. Soc., 25 (1905), No. 5, pp. 657-659*).—This paper was prepared by C. P. Fox, of Ohio, and is reprinted from the *India Rubber Journal*, August 28. It contains an account of experiments with a large number of varieties of rubber to deter-

mine their tensile strength. The data obtained are tabulated and the following conclusions drawn:

"Ceylon fine, when used to denote the oriental source of fine Para, means a grade lacking in uniformity when the tensile strength is considered. The curing qualities of Ceylon fine indicate that it has a decidedly slower action than the South American product. A future paper will show this difference more clearly. Mill deportment indicates that all of these oriental samples are much softer and are less nervous than the occidental types."

The spiral system of rubber tapping, I. ETHERINGTON (*Trop. Agr. and Mag. Ceylon Agr. Soc., 25 (1905), No. 5, pp. 641–646, pl. 1*).—A description of the spiral system of tapping worked out by C. Northway and E. D. Bowman on the Deviturai Estate in the Southern Province of Ceylon. This method of tapping is used on *Hevea brasiliensis*. It is employed only on trees which have a girth of 18 in. or more 3 ft. from the ground, or when about 5 years old.

The first time trees are only lightly tapped up to a height of 4 ft. from the ground, starting 1 ft. from the base of the tree. The first process is to mark the place for the spiral cut. This is done in stenciling ink with a sheet-tin guide. On young trees at the first tapping 2 spirals only are cut parallel and 1 ft. apart, each spiral going once around the tree. The spiral cuts are made at an angle of 45° or more; the younger the tree, the greater should be the slope. On older trees the spirals are continued up the tree to 6 ft. high or more.

The first cut in the trunk is made with a special knife, which is used as if it were a plane. The following day the cut is reopened with a paring knife having a steel spring, which works against the trunk to prevent cutting the cambium. On alternate days the shaving knife is replaced with a pricking tool, which is a small revolving spur fitted on a handle. This is run along the edge of the spiral cut, puncturing the bark close against the previous day's wound and along the wound surface. The object of the pricker is to save cutting away the bark so quickly. When the shaving knife alone was used it was found that 2 in. width of bark was cut away in one month, and when the pricker was used on alternate days only 1 in. of bark was removed per month. The flow of latex produced by the pricker seems just as full as that produced by cutting the bark.

The average yield of rubber by the V system of tapping on the estate was 1 lb. per tree per annum and by the spiral system 5 lbs. per tree per annum. In 1903, 248 trees of various girths gave 240 lbs. of rubber by the V tapping. These same trees the following season by spiral tapping yielded 1,317 lbs. of rubber. The tapped trees appear to be less injured under the spiral system than under the old V system of tapping.

In the case of young trees it is believed that tapping should not start until the trees begin to flower; that is, the fifth year. The labor required under this system is about 5 trained coolies per acre. Each cooly can tap about 400 lineal feet or 720 in. of girth per day, or 30 to 40 trees.

The yields from the trees noted above were obtained on swampy land not believed to be especially suited to rubber production. It is stated that this system of tapping is .pidly being extended.

Ceara rubber in Brazil (Manihot glaziovii), A. MOULAY (*Un arbre à caoutchouc du Brésil, le Manisoba. Paris: A. Challamel, 1906, pp. 31, figs. 16*).—A botanical description is given of this species of rubber, with an account of its culture in Brazil, including methods of extracting the latex, and the production of hard rubber.

Sapium aucuparium in Ceylon (*Trop. Agr. and Mag. Ceylon Agr. Soc., 25 (1905), No. 3, pp. 425, 426*).—It is stated that this tree is grown in Ceylon under the name of *S. biglandulosum*. It grows to a height of about 40 ft. and seeds freely. In tapping experiments the latex dried to a brittle resinous substance, and planters are advised to wait and see what products can be obtained by mixing the latex of this

species with that of Para rubber before planting extensively. Other species of Sapium found growing in Ceylon are *S. indicum*, *S. insigne*, and *S. sebiferum*. The seeds of the latter are coated with "tallow," which is used in the place of animal tallow for the manufacture of candles, soap, etc.

Species of forest trees in Soudan, M. CONSTANCIA (*Les essences forestières du Soudan, propres à la construction. Paris: A. Challamel, 1906, pp. 68*).—Descriptions are given of the various forest trees of French Soudan, with an account of their usefulness for various purposes.

Philippine wood oils, A. M. CLOVER (*Philippine Jour. Sci., 1 (1906), No. 2, pp. 191–202*).—A chemical study was made of the oils obtained from a number of Philippine woods. The principal oils studied are the oil of Supa, obtained from the tree *Sindora wallichii;* Balao, or oil of Apitong, derived from various species of the genus *Dipterocarpus*, the chief use of which appears to be in calking small boats and as a protective varnish for woods; and Malapaho, or oil of Panao, from the tree *D. vernicifluus*.

DISEASES OF PLANTS.

Incomplete experiments for 1905, L. F. HENDERSON (*Idaho Sta. Rpt. 1905, pp. 14–22*).—Brief accounts are given of a number of experiments which are in the main incomplete. The investigations included spraying for the prevention of apple scab and codling moth, combating pear blight and tomato blight, destruction of dandelions, spraying for the prevention of rose mildew and rose aphis, and spraying for the elm aphis.

The spray for the prevention of apple scab and codling moth consisted of Bordeaux mixture, to which was added some form of arsenical preparation, but the results were negative, no marketable apples being found in the orchard at the end of the season.

In the experiments with pear blight the wounds made by cutting out diseased portions of the trees were covered with a mixture consisting of sulphur and carbolic acid. This was used quite liberally in covering the wounds, and there seems to be some evidence to indicate that its use was followed by good results. The experiments with tomato blight were practically a failure, although plants from seed placed directly in the field where they were to stand were somewhat more promising than others.

In the eradication of dandelions the author applied kerosene, brine, and gasoline to the plants, and where gasoline was applied the dandelion was killed without any injury to the grass. The other treatments were not wholly efficient in destroying the weed and the grass was often destroyed for several inches about the point of application. A number of mixtures were tested for combating the rose mildew and aphis, the best results being obtained where whale-oil soap and potassium sulphid were combined.

Spraying for the prevention of elm aphis consisted of winter or early spring treatment with the lime-sulphur spray, and where well applied the trees were protected against injury. Thorough applications must be given the trees, so as to reach all the eggs, which are deposited in crevices of rough bark, especially toward the base of the trees.

Indiana plant diseases in 1905, F. D. KERN (*Indiana Sta. Bul. 111, pp. 123–134*).—A résumé is given of the plant diseases observed in Indiana in 1905, the data being compiled chiefly from reports by correspondents made in response to a circular letter sent out by the station.

The summary indicates the prevalence of the more important diseases and estimates the extent of injury as compared with the previous season, whenever possible. The various crops are taken up and under each are listed the diseases observed, and where any are known, methods are given for their prevention. Formulas are given for the preparation and use of fungicides in connection with combating plant diseases.

The occurrence of plant diseases in Vermont in 1904, L. R. JONES and W. J. MORSE (*Vermont Sta. Rpt. 1905, pp. 267–271*).—Data are given showing the mean temperature, rainfall, number of clear and cloudy days, etc., and the authors call attention to the close relationship between plant diseases and weather conditions.

Brief notes are given on a number of diseases observed during the period covered by the report, particular attention being given to those of the potato, and 2 new leaf spot diseases are described. The first of these diseases made its appearance early in July, a few plants showing small black spots on the leaves, which suggested the presence of early blight. Upon closer observation it was seen that the blackening began on the under side of the veinlets and spread more rapidly along the veins than laterally. No fungus was detected in connection with the spotting. One hill of affected potatoes was dug and the root system, tubers, and bases of the stem seemed sound. The other infected plants were kept under observation until the death of the plants in September. The spots gradually enlarged, still bearing a close resemblance to the early blight, but remained sterile.

In the authors' judgment it is a nonparasitic disease, involving the plant as a whole, the local spotting of the disease being merely a symptom. It is believed to be the same disease observed by one of the authors in Germany and also in England, and a similar trouble was noticed on specimens of the Mexican *Solanum polyadenium* in the horticulturist's potato collection.

The other disease appears to be unrecorded in this country and was first noticed on early planted Early Rose potatoes. The plants exhibited obscurely defined pale yellow spots ⅛ to ¼ in. in diameter, and the lower surfaces of the spots were covered with a delicate gray growth, evidently a Cercospora. In the gross appearance of the spots and in its occurrence and destructiveness the disease was much like that caused by *Cladosporium fulvum*, which was developing at the same time on neighboring tomato plants. This disease spread during July to another variety of potatoes in an adjacent plat and showed slight development in other plats later in the season. It caused considerable damage from hastening the death of the vines of the earlier potatoes, but did no appreciable harm on the later varieties.

The fungus is being studied to determine its specific and cultural characters.

The part taken by teleutospores and æcidia in the distribution of maize and cereal rusts, J. C. ARTHUR (*Proc. Soc. Prom. Agr. Sci., 26 (1905), pp. 94–98*).—Attention is called by the author to the recent discovery of the æcidial stage of corn rust on the common wood sorrel (*Oxalis* sp.).

Hitherto this form of the rust had not been known and knowledge of the life history of the fungus remained incomplete. Having discovered the æcidial stage of the rust, this gap is filled, but the author states that the usual infection is probably through the blowing of the uredospores from the regions where the corn is not completely killed by frost. The blowing northward of these spores may cause successive infections in new localities as the season advances, and thus spread the rust throughout the country. In addition the germinating teleutospores reach plants of Oxalis, from which direct infection to the corn plant becomes possible.

The distribution described above for the corn rust is said to apply almost equally well to some of the rusts of other cereals.

Rust problems, H. L. BOLLEY and F. J. PRITCHARD (*North Dakota Sta. Bul. 68, pp. 607–676, figs. 30*).—An account is given of rusts of cereals and other plants, the principal aim of the bulletin being to provide a compendium of the theories and known facts involved in the rusting of cereals and other important farm crops, to give the lines and results of new observations and experiments, and to cite investigations and farm practices which give promise of future success in combating or preventing crop destruction by these fungus pests. The authors describe various forms of rusts, giving an account of their effect on the host plants, the alternate generations of a number are mentioned, and accounts given of the method by which the fungus is carried over from one season to another.

Among the recent observations, attention is called to the fact that in connection with shriveled grains the authors found spore beds containing both uredospores and teleutospores beneath the bran layer, and this seemed to indicate that possibly the wheat rust could attack the plant directly from the seed. Infected seed generally may be recognized by black-pointed grains, the black points being situated at the germ end of the grain. A number of seeds of this character were planted in glass cases, but the resultant plants did not show any rust. If later experiments should confirm this possible mode of rust propagation, new light may be thrown on the entire rust problem, and the importance of proper seed selection would be shown.

Suggestions are given as to precautionary measures to be taken by farmers in order that the amount of rust may be reduced as much as possible. These include the thorough drainage of fields, the early and even maturity of the crop, thorough preparation of the soil and the use of clean seed, the selection of seed of pure varieties, treatment for prevention of smut so as to insure healthy plants if possible, keeping down weeds and volunteer plants which may carry the rust, destruction of all barberry shrubs, thorough grading of seed grain, and the rotation of crops.

Plant diseases, J. J. THORNBER (*Arizona Sta. Rpt. 1905, pp. 21, 22*).—Brief notes are given on the alfalfa leaf spot (*Pseudopeziza medicaginis*) and the common grain rust (*Puccinia graminis*).

Notes on Puccinia graminis, J. JOANNIDES (*Trans. and Proc. Bot. Soc. Edinb., 23 (1905), pl. 1, pp. 63–67*).—The author records observations on the occurrence of *Puccinia graminis* in Egypt and describes the continued existence of the rust during several years without the usual presence in the life cycle of the teleutospore condition and the subsequent æcidial stage on the barberry.

Culture experiments with rust fungi, H. KLEBAHN (*Ztschr. Pflanzenkrank., 15 (1905), No. 2, pp. 65–108, pl. 1, figs. 4*).—Notes are given on experiments carried on by the author during 1903 and 1904 with some 30 species of rust fungi.

Among the data given are special references to the wintering of *Puccinia dispersa;* the specialization of *P. digraphidis;* the alternate hosts of *P. stipæ;* the specialization of *P. caricis;* notes on *P. polygoni amphibii, P. violæ*, etc.; a new form of *Uromyces dactylidis;* the specialization of *U. scirpi;* notes on *Gymnosporangium clavariæforme* and *G. juniperinum;* the relationship between *Ochrospora sorbi* and *Æcidium leucospermum;* infection experiments with *Cronartium ribicola* on white pine, etc.

Helminthosporium gramineum and Pleospora trichostoma, F. NOACK (*Ztschr. Pflanzenkrank., 15 (1905), No. 4, pp. 193–205, pl. 1*).—A report is given of the investigations of the author on the possible relationship between these two species of fungi, and he agrees with Diedicke (E. S. R., 16, p. 64) in holding that *Pleospora trichostoma* is the perithecial form of *Helminthosporium gramineum*, the cause of the stripe disease of barley.

Investigations with *H. teres* and *H. avenæ* have thus far failed to reveal their perithecial stage.

The prevention of stinking smut of wheat and loose smut of oats, W. T. SWINGLE (*U. S. Dept. Agr., Farmers' Bul. 250, pp. 16, figs. 7*).—The author describes means for the prevention of the stinking smut of wheat and loose smut of oats, the methods detailed being the treatment with sar, which consists of a mixture of sulphur, alkali, and resin; the bluestone or copper sulphate and lime treatment; formalin treatment; and hot-water treatment. Directions are given for the use of these fungicides and for the handling of the grain after treatment.

The smut of wheat, C. MACÍAS (*Com Par. Agr.* [*Mexico*], *Circ. 27, pp. 4*).—A brief account is given of smut of wheat, with directions for its prevention.

Disease resistance of potatoes, W. STUART (*Vermont Sta. Bul. 122, pp. 107–136, dgms. 4*).—In previous publications (E. S. R., 17, pp. 262, 670) accounts are given of studies of disease resistance of potatoes. The present bulletin gives the results of investigations on the resistance of vines to blight and tubers to rot. Investigations

were also carried on upon the resistance of tubers to scab, but the results so far obtained are inconclusive.

More than 150 varieties of potatoes were brought together from Europe and this country and planted under identical conditions, some being planted in clay loam and others in sandy loam. Frequent observations were made as to the presence of diseases and the relative amount of infection. There was some evidence that some of the varieties on the sandy loam were more disposed to the early blight, due to *Alternaria solani*, than others. The same is true of resistance to tip burn.

The principal investigations, however, were in connection with the late blight (*Phytophthora infestans*). This disease made its appearance about August 10 on Delaware and Green Mountain varieties, spreading slowly, the weather conditions during August not being propitious for its rapid development. The results of the investigations of the foliage are tabulated, from which it appears that a marked difference was to be observed in varieties. The resistance that is claimed for *Solanum commersoni* to late blight was found to be unwarranted under the conditions of the experiments.

In connection with the investigations on the resistance to potato rot a careful examination was made of all tubers as soon after digging as possible, and a list of the American varieties showing the greatest resistance to rot on the sandy and the clay loams is given. Keeper, American Wonder, Dakota Red, Doe Pride, and Late Blightless were the most resistant in both sandy loam and clay loam. The comparative rot resistance of European and American varieties is discussed, and it was found that on both sandy and clay loam the Dutch, German, and English-Scotch varieties showed much less rot than did the French and American varieties. While disease resistance is important, the commercial standards of this country favor qualities in which the German and Dutch varieties are inferior to the American varieties, and at present the writer does not feel warranted in recommending them to American growers.

The relative susceptibility of varieties which form their tubers deep or shallow was investigated, it having been claimed that those forming their tubers near the surface are more subject to rot than others, and while some differences might be noted, yet in both classes of soil about the same proportion of each was affected.

Potato diseases and their remedies, L. R. Jones and W. J. Morse (*Vermont Sta. Rpt. 1905, pp. 272–291*).—In continuation of investigations reported in a previous publication of the station (E. S. R., 17, p. 261) accounts are given of spraying experiments, relation of date of digging to development of potato rot, relation of storage conditions to development of rot in potatoes, studies regarding the time and method of tuber infection by the rot fungus, and gaseous disinfection for potato scab.

The spraying experiments, which were conducted for the prevention of both late blight and rot, were carried on in the field. Bordeaux mixture, consisting of 6 lbs. of copper sulphate, 4 lbs. of lime, and 40 gal. of water, with the addition of ½ lb. of Paris green, was employed, 2 applications of the mixture being given the plants on August 2 and 21, respectively. At the expiration of the season the tubers were dug, and the gain at the rate of 161 bu. per acre is attributed to the application of the fungicide. The authors present in tabular form the gains from the use of Bordeaux mixture on late potatoes, covering experiments for the past 15 years in which the average gain for that period is 119 bu. per acre due to the treatment.

In a previous report (E. S. R., 14, p. 1084) the authors called attention to the method by which the spores of the fungus are carried from the leaves to the tubers, and suggested spraying the soil with Bordeaux mixture for preventing this infection. The previous trials were repeated in 1905 with good results, and the investigations show that not only does the disease pass from the leaf to the tuber, but the main channel is through the soil rather than through the stem. Spraying experiments for the control of the early blight showed the effect of thorough application of the fungicide,

the increased yield being attributed to the beneficial effects of the Bordeaux mixture, not only in checking the development of the fungus, but in deterring insect attacks.

In investigations on the relation of the date of digging to the development of the potato rot, results quite different from those previously reported (E. S. R., 17, p. 261) were obtained. In 1905 there was a greater loss from later digging than from earlier, and this is at variance with the previous rule laid down that digging should be deferred as long as possible where the rot is expected. In the authors' opinion this rule will have to be modified by making an exception of heavy wet soils during wet seasons.

Experiments were carried on to test the effect of liming, disinfection with formalin, sun-drying the tubers, and the temperature of storage on the development of rot in potatoes. It was found that instead of being an advantage in the preservation of tubers, the application of lime actually favored the development of rot. Disinfecting with formalin was without any material effect in checking it. In testing the relation of moisture to the development of rot it was found that potatoes exposed as much as practicable to sun and air prior to storage are less subject to rot than those stored immediately. The various temperatures of storage investigated were 40, 53, and 70°, and the greatest proportion of the crop saved was at the lowest temperature.

In studying the time and method of tuber infection different lots were subjected to different treatments. One lot was exposed for 36 hours to infection from blighting tubers immediately after digging, a second lot was not artificially infected but kept moist for 36 hours, and a third lot was stored without treatment immediately after digging. The relative loss was 92 per cent where the tubers were infected and not washed, 100 per cent where infected and washed, 77 per cent where not infected but kept moist for 36 hours, and 54 per cent where stored at once without any treatment. Concerning the possibility of spread in the storage cellar, it was found that spores may be produced in storage, and that well ripened sound tubers were readily inoculated with the fungus spores. From this it appears that there is no doubt as to the possibility of infection of tubers in storage.

In continuation of trials of gaseous disinfection for potato scab (E. S. R., 17, p. 261), the authors tested the relative value of gas treatment as compared with soaking seed for disinfection against scab, and also the merits of different ways of generating the gas. All the methods of disinfection showed marked gains in smooth tubers, but none of them gave a crop wholly free from scab. The average results obtained with the vapor treatments were better than those secured where the seed tubers were soaked in formalin solution, and the authors are led to recommend treatment of seed tubers with formalin gas by the permanganate method without the addition of steam. The cost of this treatment would be approximately $1.50 per 1,000 cu. ft., and this method is recommended only for those seed potato specialists who may wish to disinfect large quantities of tubers.

Concerning disease resistance of potatoes, L. R. JONES (*Vermont Sta. Rpt. 1905, pp. 264–267*).—A brief account is given of investigations carried on by the author in connection with the Bureau of Plant Industry of this Department regarding the resistance of potatoes to various diseases, a preliminary report on which has already been issued (E. S. R., 17, p. 60).

The potato leaf curl (*Jour. Bd. Agr. [London], 12 (1905), No. 8, pp. 476–478, fig. 1*).—A description is given of the potato leaf curl or early blight (*Macrosporium solani*), and its occurrence is noted on *Solanum commersoni* grown at Kew.

Sal Bordeaux for potato blight, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 126, pp. 34, 35*).—In a previous publication of the station (E. S. R., 16, p. 1093) it was shown that dry Bordeaux as a fungicide was inferior to Bordeaux mixture as usually applied.

In 1905 an experiment was carried on to test the value of a dust spray known as Sal Bordeaux. This consists of equal parts of lime and exceedingly finely ground

copper sulphate, and it is applied as a dust on the theory that as soon as this dust becomes moist, from dew or otherwise, the regular Bordeaux mixture in concentrated form will be produced on the foliage. A number of plats received treatment with this fungicide at the rate of 3, 6, and 10 lbs. per acre. There was no blight on either the treated or untreated plats, so the results are considered inconclusive, and it is planned to repeat the experiment in 1906.

In connection with these experiments Paris green was used to prevent the ravages of bugs, and where it was applied in connection with the dry powder it was not as efficient as where the insecticide was administered in the form of a spray.

Further experience in asparagus rust control, R. E. SMITH (*California Sta. Bul. 172, pp. 21, figs. 7*).—In continuation of experiments previously reported (E. S. R., 16, p. 66; 17, p. 48), the author gives an account of experiments carried on in California and elsewhere to control the asparagus rust, the principal information in the present publication being based on the results of practical work of various growers, especially observations made in connection with a ranch at Milpitas, Cal.

At this ranch the asparagus cutting was stopped about the first of July, and the rust was less abundant than usual on the uncut tops, but developed very vigorously after the beds grew up. An especial effort was made to keep down the wild growth about the edges of the field, which had in previous years caused a large amount of infection. After the end of the cutting season and the usual plowing and cultivation, the field was irrigated in order to start as vigorous a growth as possible. About August 1 heavy dews occurred, and the first application of sulphur was made. A special form of apparatus was employed, and sublimed sulphur at the rate of about 100 lbs. per acre was applied. Three weeks later a second application was made, and a third was given after a second interval of about 3 weeks.

The results of the treatment were quite apparent from the condition of the treated field. All untreated fields in the neighborhood were badly rusted in September and the tops were black and dead in October, while the field receiving the sulphur made a fine growth and the plants remained green until the normal end of the season. The cost of the treatment was at the rate of $6 per acre for the season's work on 75 acres, and from the experience obtained it was thought possible to reduce this cost to about $4 per acre for future treatments.

Other growers in the same locality applied sulphur to asparagus, and the results obtained were in proportion to the efficiency of the application. Near Sacramento attempts were made to control the rust with liquid sprays, and where Bordeaux mixture alone was used the effect on the rust was very slight. When sulphur was used in connection with the sprays, much better results were obtained, and based upon the trials of a number of growers, the following treatment has been adopted for future use: Three weeks after cutting, the plants are to be sprayed with whale-oil soap and water, followed by a dusting of sulphur at the rate of about 150 lbs. per acre. One month later sulphur is dusted over the plants at the rate of about 200 lbs. per acre, the applications to be made on dewy mornings.

The author cites illustrations of the use of sulphur for the control of the asparagus rust in other localities in California and also in South Carolina, where the treatment proved eminently successful.

In applying the sulphur the chief requisite is to scatter it so that it will cover all the growth in a dusty, smoky cloud. Experiments with ground and sublimed sulphur and flowers of sulphur showed that when all things are considered the flowers of sulphur is the most satisfactory and economical.

In conclusion the author states that in treating asparagus it is necessary to get a good coating of sulphur on the tops just before the rust is due to appear. A second application should be made 1 month later, and a third after another interval of about 4 weeks. Where young beds of asparagus are to be protected from rust, the author recommends a special form of treatment, which consists of spraying the

plants with whale-oil soap, to be followed by an application of sulphur, scattered by hand.

White rust of cabbages (*Jour. Bd. Agr.* [*London*], *12* (*1905*), *No. 8, pp. 480, 481, fig. 1*).—A brief account is given of the occurrence of *Cystopus candidus* on cabbages. As the white rust most frequently occurs on shepherd's purse, it is recommended that all weeds of this kind should be destroyed in the vicinity of other crops that are liable to be infected by the fungus.

Tomato diseases in California, R. E. SMITH (*California Sta. Bul. 175, pp. 16, figs. 8*).—A preliminary report is given on the cause, nature, and possible means of prevention of some diseases of the tomato which have become exceedingly destructive in parts of California, and the further investigation of which is to be prosecuted in connection with the work of the new pathological laboratory for southern California.

The diseases described are the damping-off, which is due to one or more species of fungi, the summer blight, which is attributed to attacks of an undetermined species of Fusarium, and the winter blight, which is caused by the fungus *Phytophthora infestans.* For the damping-off, which is most prevalent in seed beds, the use of fresh earth, thorough ventilation, and the avoidance of overcrowding the plants are recommended as precautionary measures, and spraying with Bordeaux mixture, followed by sprinkling with sulphur, is advised where the disease has become established.

For the summer blight, which is due to a soil fungus, the only recommendation that can be made at present is planting healthy plants in new soil. Applications of lime, sulphur, etc., to the soil may be tried, but the effect of such treatment has not yet been demonstrated. Spraying can probably be of no use in connection with this disease. For the prevention of the winter blight, which occurs only after heavy rains or heavy fogs and dews, and in California affects only the winter crop of tomatoes, spraying after every rain with Bordeaux mixture is recommended.

A Fusarium disease of tomatoes, E. VON OVEN (*Landw. Jahrb., 34* (*1905*), *No. 3-4, pp. 489-520, pls. 2, fig. 1; abs. in Centbl. Bakt.* [*etc.*], *2. Abt., 15* (*1905*), *No. 15-16, pp. 491, 492*).—In 1901 and again in 1904 there appeared on tomatoes in the vicinity of Berlin a disease that became epidemic, causing considerable losses of the fruit.

Upon the blossom end of both green and ripe fruit appeared black spots that enlarged, and, through the softening of the underlying tissues, gave a wrinkled appearance to the fruit, which finally became a dried mummified mass. An investigation of the material showed there was a fungus in the tissues, and also abundant bacteria. Subsequent studies seemed to show that the bacteria were of secondary importance, finding entrance only after the destruction had been begun by the fungus.

The cause of the disease is said to be a species of Fusarium. The fungus appears to be usually a wound parasite, under normal conditions not being able to penetrate the epidermis of the fruit, but when especially abundant and vigorous in growth it seems to cause infection.

The author describes the results of inoculation experiments with the organism, which seems to be an exceedingly variable one, and which survives the winter in the numerous sclerotia formed in the mummy fruits. The fungus is described as a new species, with the name *Fusarium erubescens,* and it is critically compared with several other species of Fusarium.

Experiments have shown that weak solutions of Bordeaux mixture have little effect in checking the growth of the fungus. Therefore it is suggested that tomatoes should be sprayed with strong solutions of Bordeaux mixture as soon as the disease makes its appearance.

Bacterial disease of tomatoes (*Bd. Agr. and Fisheries* [*London*], *Leaflet 152, pp. 2, fig. 1*).—A description is given of a bacterial disease of tomatoes that has been

known as occurring in France for a considerable time, where it has assumed the proportions of a destructive epidemic. It has been recently reported in several widely separated localities in England, on which account attention is drawn to it.

The symptoms of the disease are said to be very marked and can not be confounded with those of any other tomato disease at present known. When the tomato is about the size of a marble a minute black patch appears at the base of the style. This patch gradually increases in size, retaining a circular outline, until eventually the entire fruit is reduced to a blackish, soft, decayed mass.

Experiments have shown that infection takes place during the flowering stage and that the bacteria causing the disease are deposited on the stigma by flies visiting the flowers.

The stigma seems to be the only vulnerable part under ordinary conditions, but if bacteria from a diseased fruit are introduced into the flesh of a healthy tomato, infection follows.

The disease does not appear to be influenced to any extent by the forcing methods commonly followed, as it has been observed in houses where the temperature was kept comparatively low.

When the disease appears all diseased fruit should be removed as quickly as possible, and insects should be excluded by using insecticides. Where this is done, artificial pollination will be necessary.

The blight canker of apple trees, H. H. WHETZEL (*New York Cornell Sta. Bul. 236, pp. 101–138, figs. 36*).—A description is given of a form of apple-tree canker which is due to the same cause as that which produces the bacterial or fire blight of the pear. It seems to be favored by rapid growth of the trees, and the points of inoculation are water sprouts, wounds, and possibly the flowers. After reviewing the different kinds of cankers that have been described as occurring on apple trees, the author gives the distinguising characters and appearance of the canker treated in this bulletin, which is due to *Bacillus amylovorus*.

These cankers occur most frequently on the bodies and limbs of young trees, and the diseased areas are sunken and smooth, covered with a brown surface, but not showing any pimples or fungus fruit bodies, which characterize some of the other forms of fruit-tree canker. The effect of the disease on the tree is to lower its vitality by cutting off the food supply to the roots and indirectly reducing the flow of sap to the branches and leaves.

Inoculation experiments have shown that the disease can be readily caused through wounds. As preventive measures the author recommends the burning of all dead limbs and trees as promptly as possible and cutting out and burning every trace of twig blight on both apple and pear trees as soon as detected. When pruning, all cut surfaces should be treated with corrosive sublimate or copper sulphate solution. Water sprouts should be cleaned from the trees, and the excessive use of nitrogenous fertilizers should be avoided. When possible the planting of varieties known to be resistant to the disease is recommended. Wolf River and Talman Sweet appear to be quite resistant, while Baldwin and Ben Davis suffer severely. In order to prevent the spread of the disease the author suggests an early spring treatment with lime-sulphur wash.

Notes are given on the distribution and severity of the disease throughout New York, and a detailed account is given of the identity of the organism, and notes on its morphology, cultural relation, etc. A bibliography of the publications relating to this disease completes the bulletin.

A fungus disease of the mandarin orange, P. A. SACCARDO (*Separate from Ann. Mycol., pp. 3; abs. in Ztschr. Pflanzenkrank., 15 (1905), No. 3, p. 175*).—The author states that mandarin oranges were noticed in Naples that showed dark spots on the rind, the spots later becoming confluent.

Upon examination the rind was found matted with mycelium which when old became of a dark violet color. When placed in a moist chamber there soon developed on the rind violet black hyphæ and conidiophores that characterize *Alternaria tenuis*, but the fungus differed in some respects from this species. The author has described it as a form of the above species, naming it *A. tenuis chalaroides*.

A disease of bananas in Central America, H. PITTIER DE FABREGA (*Jour. Agr. Trop., 5 (1905), No. 54, pp. 379, 380*).—A brief account is given of a disease of bananas, the origin of which is in doubt, but which has caused the destruction of hundreds of hectares of plants in Costa Rica and Panama. The author holds that the disease is due to faulty drainage, the soil having been saturated by heavy rains and lacking cultivation.

The American gooseberry mildew, J. ERIKSSON (*K. Landtbr. Akad. Handl. och Tidskr., 44 (1905), No. 4-5, pp. 273-288*).—The author describes *Sphærotheca mors-uvæ*, which is said to have first appeared in Sweden in 1902 and in Ireland in 1900, in Russia in 1901, and in Denmark in 1904.

An account is given of the distribution of the fungus in the United States, its life history, and methods of combating it. Among the protective measures recommended are the planting of healthy stocks, early destruction of badly affected bushes, and spraying the bushes and ground with potassium sulphid (30 gm. to 10 liters of water). When bushes are only slightly affected the diseased parts should be cut off and burned in the fall and the bushes sprayed early in the spring before the leaf buds appear. The spraying should be repeated every 8 to 14 days until the berries have attained about half their mature size.—F. W. WOLL.

Black blight in Granada, R. D. ANSTEAD (*Agr. News [Barbados], 4 (1905), No. 96, p. 394*).—In a report to the Agricultural Committee of Granada, the author deals with the nature and control of the black blight that is prevalent in that island, attacking mango, bread fruit, sapodilla, guava, and rose apple trees. The blight is due to a species of Capnodium, which follows the presence of a number of scale insects.

For the prevention of the disease the author recommends cultivation of the plants, clean culture, and the use of insecticides against the scale insects.

Gray blight of tea, T. PETCH (*Trop. Agr. and Mag. Ceylon Agr. Soc., 25 (1905), No. 5, pp. 630, 631*).—The author gives a note on the gray blight of tea, which is attributed to the fungus *Pestalozzia guepini*, and calls attention to the fact that spores indistinguishable from those producing the gray blight are formed on rose leaves attacked by *Actinonema rosæ* when kept in a moist chamber for some days. This form has been called *P. suffocata*, but the author believes the differences are so slight as to indicate the possible identity of this species with the one above.

The gray patches on tea leaves are said to be well known, but in some cases the fungus attacks the leaf stalk at the junction of the stem, in which case the leaf turns brown, falling from the bush before producing any indications of the disease on the leaf. The stem of the bush may also be attacked, the fungus entering the young shoot at the cut end left in gathering the tea, in which case the young shoot is killed to the base. It also occurs on stems an inch or more in diameter, forming a kind of canker. A similar fungus is said to attack *Hevea brasiliensis*, causing slight damage to the leaves, but the plants in a short time recover from the attack.

The bud rot of the cocoanut palm (*West Indian Bul., 6 (1905), No. 3, pp. 307-321; noted in Agr. News [Barbados], 4 (1905), No. 95, pp. 369, 370*).—Mention has already been made of the occurrence in various parts of the West Indies of a serious disease of cocoanut palm known as the bud rot. This has recently become prominent in Trinidad, where one plantation reports the loss of 2,000 trees in 6 months.

The cause of the disease has been attributed to the fungus *Pestalozzia palmarum*, but recent investigations (E. S. R., 17, p. 158) seem to indicate that bacteria play an important part.

It is said that probably no remedial measures will be found effective in the case of palms already seriously attacked, but to prevent the further spread of the disease all affected palms should be cut down and burned or buried with lime. Experiments in Jamaica have shown that spraying with Bordeaux mixture on the first indication of the disease is somewhat effectual. As the disease is of a virulent character, energetic efforts are recommended to stamp it out.

A green-skinned variety of cocoanut in Jamaica is said to be less liable to bud rot than the yellowish and reddish varieties commonly grown, and if this should be confirmed it may be possible to establish a race of cocoanuts resistant to disease.

Cacao disease in Ceylon (*Trop. Agr. and Mag. Ceylon Agr. Soc., 25 (1905), No. 2, pp. 293-296*).—The cacao trees in Ceylon are subject to a serious disease, which finds favorable conditions for its spread in dense shade and abundance of moisture commonly found on cacao plantations.

The disease, which is of fungus origin, attacks both fruit and stems. The pods become dark brown or black, and unless controlled the disease spreads rapidly. The disease can be restrained by collecting and destroying the diseased pods at frequent intervals, or by spraying with Bordeaux mixture. In addition the shade should be removed to some extent and the diseased tissues of the stems collected and burned.

In 1902, 96 per cent of the trees and 14 to 62 per cent of the pods of a plantation were attacked by the fungus. The preventive measures described above were begun in 1902 and within 6 months an improvement was noted. In 1904 less than 4 per cent of the fruit was attacked and the yield increased from 0.83 cwt. per acre in 1902 to over 2 cwt. in 1904.

Canker of rubber, T. PETCH (*Trop. Agr. and Mag. Ceylon Agr. Soc., 25 (1905), No. 2, p. 298*).—In a report on the canker of *Hevea brasiliensis* mention is made of the fact that a large portion of the fruit did not ripen and split in the normal way, but remained on the tree and blackened or fell off without splitting.

An examination showed that this condition is due to a parasitic fungus similar to, if not identical with, that which causes the decay of cacao pods, which is generally attributed to *Phytophthora omnivora* and *Colletotrichum incarnatum*, the first of which is the more destructive. The Hevea fruits examined were all attacked by a species of Phytophthora which permeates the soft outer tissues of the fruits, causing the seeds to dry up. All diseased fruit should be collected and burned as a precautionary measure.

A disease of Hevea seedlings, T. PETCH (*Trop. Agr. and Mag. Ceylon Agr. Soc., 24 (1905), No. 12, p. 138*).—A report is given of leaves of Hevea seedlings being attacked by a species of Helminthosporium.

The leaves were studded with circular, semi-transparent spots, each surrounded by a brown layer. It is thought probable that the spots are due to insect punctures and that the fungus gains access to the tissues through these injuries. As a consequence of this discovery a number of nurseries of this species of rubber were examined without discovering much disease, but there were found commonly present injuries that seemed to be due to fungi, the most common of which was *Periconia pycnospora*. It is believed that the fungi were present as a result of mechanical injury, which in many instances is attributed to the burning of the leaves by light shining through globules of water collected on the foliage.

The destruction of Siberian firs in Adlisberg, H. C. SCHELLENBERG (*Mitt. Schweiz. Centralanst. Forstl. Versuchsw., 8 (1905), No. 3, pp. 269-286, pl. 1*).—In 1901 the author examined a plantation of Siberian firs that was about 30 years old and found many of the trees suffering from the attacks of some fungus. Upon closer investigation the bark was found thickly studded with the small orange-yellow fruiting bodies of *Dasyscypha calyciformis*, and where these bodies were abundant the

bark was dead and of a reddish color. The trees in general appeared unhealthy and many were dead.

Subsequently studies were made of the fungus, and comparisons are drawn between this and allied species. The development and life history of the parasite are described, after which notes are given on inoculation experiments carried on in the forest, the amount of injury caused, etc.

Root rot of logwood trees (*Agr. News [Barbados], 4 (1905), No. 96, p. 389*).—This disease, which was previously described (E. S. R., 14, p. 882), causes the destruction of trees in considerable number through the presence of a mycelium invading the roots and spreading upward into the trunk, between the bark and the wood. Although the fruiting organs of the fungus have not been discovered, it is believed to be a hymenomycete.

The disease is found in trees growing in different kinds of soils and under varying climatic conditions, and has been recently reported as spreading rapidly in Jamaica. It is contagious, spreading through the soil, and to prevent its further spread it is recommended that trenches 3 ft. deep be dug about the diseased area, when confined to definite patches. Where it is widely disseminated the clearing of the infested tract and cultivation with other crops are recommended.

Some Indian forest fungi, E. J. BUTLER (*Indian Forester, 31 (1905), No. 10, pp. 548–556, figs. 3*).—After discussing fungus diseases in general, the author describes the attacks of *Chrysomyxa himalense* on rhododendrons and different forms of *Gymnosporangium cunninghamianum*, the æcidial form of which occurs on *Pyrus pashia* and the teleuto form on cypress.

Some rose diseases, E. FOEX (*Prog. Agr. et Vit. (Ed. l'Est), 26 (1905), No. 48, pp. 616–619, pl. 1*).—The author describes the rose rust, due to *Phragmidium subcorticium*, the rose mildew (*Sphærotheca pannosa*), and the attacks of *Marsonia rosæ*, which causes the premature falling of the leaves.

For the control of the mildew the author recommends spraying with a mixture of carbonate of soda 1.5 kg., Norwegian tar 0.5 kg., and water 100 kg.

North American salvia rusts, E. W. D. HOLWAY (*Jour. Mycol., 11 (1905), No. 78, pp. 156–158*).—Technical descriptions are given of a number of species of rusts that are known to attack various species of salvia, and *Puccinia infrequens*, *P. badia*, and *P. nivea* are described as new species.

A new orchid disease, G. MASSEE (*Gard. Chron., 3. ser., 38 (1905), No. 973, pp. 153, 154, fig. 1*).—A description is given of a recently recognized disease of Oncidium, which is attributed to *Hemileia americana* n. sp.

This fungus, which is closely allied to that causing the most destructive coffee disease, threatens to become a serious pest in orchid culture if it once becomes established. The fungus forms bright orange, powdery-looking patches of various sizes on the under surface of the leaf, with corresponding areas of a sickly yellowish-green color on the upper surface. On account of the threatened seriousness of this disease, the prompt destruction of every leaf showing the symptoms above indicated is recommended.

An orchid disease, H. KLITZING (*Gard. Chron., 3. ser., 38 (1905), No. 980, p. 259*).—A description is given of *Glœosporium beyrodtii*, a new species which appears in dense masses on both sides of the leaves of *Vanda cœrulea*. The spots sometimes run together, forming dark blotches, and finally bring about the destruction of the entire plant. The fungus is briefly characterized.

The action of copper salts on plants, F. PORCHET and E. CHUARD (*Bul. Murith. Soc. Valais. Sci. Nat., 1904, No. 33, pp. 204–210, pl. 1*).—This bulletin, which was issued in 1905, gives an account of experiments which have been carried on at the Viticultural Station of Lausanne since 1886 to test the effect of copper compounds on plants, especially the practical effect in reducing disease, and the effect of fungicides on wines made from sprayed grapes.

The physiological effect of fungicides on the plants themselves, particularly with reference to fruit maturing, has also been determined. The investigations showed that treating vines with copper solutions resulted in a stimulation of growth, through the absorption of minute traces of copper, and the ripening period of the grapes was also accelerated.

To determine the penetration of copper into plant tissues an experiment was inaugurated in the spring of 1903 in which different lots of grape cuttings were potted in a peaty leaf mold and the different pots given varying amounts of copper, iron, magnesium, and cadmium salts in solution, the concentrations varying from 0.001 to 1 per cent. In 10 days the lots receiving the weaker solutions of copper began to force their buds. Eleven days later those which had received magnesium sulphate had 4 leaves, and the buds on the cuttings receiving 0.01 and 0.001 per cent copper sulphate were bursting. All others showed no growth.

At the end of 33 days all buds had burst except those receiving iron sulphate, and these were more than 2 months in developing. In the autumn it was observed that the leaves remained on the treated vines long after the check lots had lost their leaves, and the cuttings treated with magnesium sulphate and iron sulphate lost their leaves before those which received the copper sulphate solution. These retained their foliage late into the fall, ultimately losing them in direct proportion to the strength of solution with which they had been treated.

The quantity of copper in the different lots was determined late in the autumn, and it ranged from 0.0133 gram of copper per 100 gm. of dry weight for the lot receiving a 1 per cent solution to a trace in the lot receiving 0.01 per cent, and not even a trace where the more dilute solutions were used.

Recognizing the corrosive action of copper sulphate on the delicate roots formed from cuttings, this feature was investigated, and it was found that the humus in the pots had acted on the copper, causing it to lose its toxic effect upon the root tissues.

The adulteration of copper sulphate (*Jour. Bd. Agr.* [*London*], *12* (*1905*), *No. 9, pp. 542, 543*).—On account of the extensive use of copper sulphate as a fungicide and the corrosive effect of some impurities, the writer suggests that in purchasing this material demand should be made for a product of 98 per cent purity. This is practically a pure copper sulphate and is without the corrosive effect that is observed in some of the adulterated specimens.

The results of the analysis of an adulterated sample show that it contained 17.6 per cent crystallized copper sulphate and 82.4 per cent crystallized iron sulphate. As an easy test for the presence of iron in copper sulphate the writer suggests dissolving a little in water and adding ammonia with constant stirring until a liquid of a deep blue color is formed. If iron is present in any quantity it will be shown by the occurrence of brown flocculent masses floating in the blue liquid.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Agricultural zoology, G. Guénaux (*Zoologie Agricole. Paris: J. B. Baillière & Son, 1905, pp. XII + 563, figs. 168*).—The present volume includes a general discussion of the importance from an agricultural standpoint and the use of farm animals, together with an account of the habits and economic relations of birds, reptiles, amphibians, and small mammals. Particular attention is given to the feeding habits of the various species discussed.

Protection of birds which are beneficial to agriculture (*Jour. Agr. Prat., n. ser., 10* (*1905*), *No. 52, pp. 816–818*).—An international convention was held in Paris on December 6, 1905, at which time various European countries were represented, including France, Germany, Austria-Hungary, Belgium, Spain, Greece, Sweden, Switzerland, etc. The purpose of this convention was to adopt a uniform method of procedure regarding the protection of beneficial birds.

At this convention 16 articles or resolutions were adopted and some of the more important points mentioned in these resolutions may be briefly stated in this connection. Insectivorous birds, of which a list is given and to which additions may be made as more knowledge is gained concerning the feeding habits of these birds, are recommended for absolute protection as well as their nests and eggs. More stringent legislation is recommended for preventing the destruction of nests and eggs and the use of traps, cages, nets, and other devices for capturing birds. The proprietors of vineyards or gardens are to be granted the privilege of destroying birds in case they should become injurious on the premises in question. A list is also given of injurious birds.

Special report on the decrease of certain birds and its causes with suggestions for bird protection, E. H. Forbush (*Agr. of Mass., 52 (1904), pp. 429–543, pls. 2*).—An elaborate historical account is given of the former prevalence of birds in Massachusetts and neighboring States and the decrease in numbers of these birds due to various causes.

Among the agencies which may affect the destruction of birds the author enumerates the unfavorable weather of 1903–4, the destruction of birds by sportsmen, bird shooters and trappers, market hunters, boy gunners, and egg collectors. Apparently six species of game birds and water fowl have disappeared in Massachusetts within historical times and shore birds are estimated to have decreased in numbers to the extent of 75 per cent. Swallows, night hawks, eagles, great blue herons, house wren, red-headed woodpecker, and various other species of similar birds are on the decrease.

Notes are given on the natural enemies of birds, especially cats and English sparrows. In order to protect birds from further unnecessary depredations it is suggested that more attention be given in the schools to the economic value of birds and the desirability of protecting them.

Animal and insect pests, E. Wright (*Queensland Agr. Jour., 16 (1905), No. 1, pp. 67–70*).—The flying fox is considered as one of the most important fruit pests along the eastern coast of Queensland. Notes are also given on certain birds which are injurious to fruits as well as on the fruit fly and other insect pests.

Entomology with special reference to its biological and economic aspects, J. W. Folsom (*Philadelphia: P. Blakiston's Son & Co., 1906, pp. VII + 485, pls. 5, figs. 300*).—According to the author this volume is intended for the student and general reader, and was written to cover as fully as possible within the limits of the book the biological aspects of insects.

The subject-matter is arranged under the heads, classification; anatomy and physiology; development; adaptations of aquatic insects; color and adaptive coloration; origin of adaptations; insects in relation to plants, animals, and man; insect behavior; and distribution. A classified bibliography of important entomological literature is also presented (pp. 409–466). The literature of economic entomology is discussed. One of the most valuable features of the book is the discussion of the economic relations of insects.

Catalogue of publications relating to entomology in the library of the U. S. Department of Agriculture (*U. S. Dept. Agr., Library Bul. 55, pp. 562*).—This bulletin contains a classified list of 5,600 publications relating to entomology in the library of the Department. The titles are grouped under general entomology, economic entomology, faunas, and various orders of insects, Myriapods, and Arachnida A list of serial publications relating to entomology is also given and the bulletin is provided with an index to insect families and authors.

Insects of the year, W. Stuart (*Vermont Sta. Rpt. 1905, pp. 309–314, figs. 2*).—No serious outbreaks of injurious insects occurred during the season, but the usual number of requests were made concerning insect injuries of lesser importance.

Among the injurious species of which brief notes are given are woolly aphis, red-humped apple-worm, oyster-shell bark-louse, and apple-leaf miner.

The periodical cicada in 1906, C. L. MARLATT (*U. S. Dept. Agr., Bur. Ent. Circ. 74, pp. 5, figs. 3*).—During the present season two broods of the periodical cicada will reappear, one being a 17-year brood and distributed from Illinois to Massachusetts and southward to Georgia. The other is the 13-year brood and is distributed in North Carolina, Georgia, Alabama, and Tennessee. Brief notes are given on the damage done by this pest. The broods are expected to appear about the last week in May.

Studies in grasshopper control, J. S. HUNTER (*California Sta. Bul. 170, pp. 28, figs. 17*).—During 1904, grasshoppers were very injurious in the San Joaquin Valley, where they hatched out in April or earlier and appeared in large numbers early in May. Various crops are raised on the infested ground, but in one locality the grasshoppers were found very injurious in an area of about 2,000 acres devoted to alfalfa. The species concerned in this outbreak are *Clinopleura melanopleura*, *Melanoplus uniformis*, *M. devastator*, and *Œdaleonotus enigma*.

In combating grasshoppers it was found possible to destroy the young insects by burning the grass where the ground was fairly well covered. The winged form were also destroyed by the same means if the work was done during cool nights. Considerable success was had in poisoning grasshoppers, not by the Criddle mixture, which was unsatisfactory, but by the use of a poison bait which contained 5 lbs. of arsenic in 40 lbs. of bran moistened with 2 gal. of molasses. Hopperdozers could not be used as effectively in orchards as in alfalfa fields. Occasionally good results could be obtained by smoking the grasshoppers out of the fields. Near Newman the injurious species was *Melanoplus differentialis*. This pest defoliated vineyards and orchard trees, eating the fruit.

The Hessian fly, F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Circ. 70, pp. 16, figs. 16*).—A general account is presented of this important insect of wheat with notes on its early history, appearance, stages, habits, distribution, food plants, and injuries.

There appears to be no variety of fly-proof wheat, although macaroni wheat is somewhat less injured than other kinds. The natural enemies of the pest are discussed, and notes are given on the various remedies which have been tried for this insect, late sowing, crop rotation, burning of stubble, destruction of volunteer wheat, use of fertilizers, preparation of the soil, and use of good seed. In preventing the attacks of the Hessian fly the author recommends that good seed should be sown in well-prepared soil after the larger part of the fall brood has made its appearance. In spring seeding it is believed that the earlier wheat is sown the less danger there will be from the Hessian fly.

Some insects affecting the production of red clover seed, F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Circ. 69, pp. 9, figs. 8*).—Particular attention is given in this circular to the clover-flower midge and clover-seed chalcis.

It is believed that the clover-flower midge does not really infest the seed but lays its eggs in the ovaries before fertilization has taken place. The clover-seed chalcis, however, lives in the seeds only. No insects like bumblebees are able to fertilize clover which has been infested with the clover-flower midge. This insect is described in all its stages and notes are given on its life history. It has been reported as quite common in England and occurs in this country wherever clover is grown.

The best methods of controlling it consist in cutting clover not later than the second week in June in fields where clover is grown without much admixture of timothy. This operation seems to destroy the larvæ of the midge and also to hasten the second blooming so that the flowers are too far advanced for infestation by the midge. In cases where clover and timothy are grown mixed, the same results may be obtained by pasturing clover in the spring so as to delay the flowering period.

The clover-seed chalcis is also described and notes are given on its life history. This pest attacks the seed of red and crimson clover and also alfalfa. It is distributed also from New England to California on the west, and south to Mississippi. Insect enemies capable of controlling the pest are not known. Remedies recommended for the clover-flower midge might apply to this insect, and it is also suggested to destroy scattering heads of clover together with the chaff and stems after hulling.

The clover root borer, F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Circ. 67, pp. 5, figs. 4*).—This insect is a native of Europe and has become generally established in the eastern States. It attracted attention in 1878 in New York and has gradually spread toward the Mississippi River.

The insect is described in its various stages and notes are given on its life history and food plants. There appears to be but one annual generation. It feeds on red clover and alfalfa as well as other species of clover. Infested clover plants sooner or later die as a result of the attack of this insect. Apparently the only successful way of combating the pest is summer fallowing as soon as the hay crop is removed.

The tobacco thrips and remedies to prevent "white veins" in wrapper tobacco, W. A. HOOKER (*U. S. Dept. Agr., Bur. Ent. Circ. 68, pp. 5, figs. 2*).—*Euthrips nicotianæ* was described in September, 1905. The insect injures shade-grown cigar-wrapper tobacco in Florida, Georgia, and Texas.

The removal of the sap from the lateral veins of the leaves causes white streaks when the leaves are cured. This is objectionable from the standpoint of the cigar maker and reduces their value about 50 per cent. The adult insect appears to pass the winter in the tobacco fields. They deposit their eggs in the tissues of the stem and leaves and the young larvæ feed on the under surface of the leaves and the adults feed upon the upper surface. In combating this species clean cultivation is recommended. The pest appears in oats and it is urged that this crop be not planted in the vicinity of tobacco fields.

As an insecticide application the author recommends the use of kerosene emulsion according to the formula 2 gal. of kerosene, 1 gal. of water, and ½ lb. of hard soap diluted to make 10 gal. A number of applications should be made while the plants are in the seed bed and later in the field about two applications a week may be required. The expense of such an application does not exceed $20 per acre.

Pea and bean beetles (*Bd. Agr. and Fisheries [London], Leaflet 150, pp. 4, figs. 2*).—Descriptive, economic, and biological notes are given on *Bruchus pisi* and *B. rufimanus.*

The turnip mud-beetle, R. S. MACDOUGALL (*Jour. Bd. Agr. [London], 12 (1905), No. 2, pp. 102–104, fig. 1*).—*Helophorus rugosus* is quite widely distributed throughout England and Scotland. It attacks turnips by eating the leaves and tunneling the leaf stalks and roots. The injury is done both by the beetle and larvæ. Rotation of crops is recommended in controlling this pest, together with the liberal use of fertilizers.

The use of bisulphid of carbon against wireworms (*Jour. Bd. Agr. [London], 12 (1905), No. 2, pp. 104, 105*).—It has been found that the character of the soil largely determines the rate at which the fumes of this gas diffuse from the point where it was injected into the soil. In using bisulphid of carbon against wireworms little benefit can be expected on very wet soils, and the application should be made before the damage from the wireworms is too far advanced, and moreover the bisulphid of carbon should not be allowed to come in contact with the roots of the plants.

Report of the State nursery inspector, H. T. FERNALD (*Agr. of Mass., 52 (1904), pp. 243–247*).—Of the pests which require the attention of the inspector in Massachusetts, San José scale, oyster-shell scale, gypsy moth, and brown-tail moth are the most important. Brief notes are also given on black knot and other fungus diseases.

Report on work done in 1903-4 in the control of San José scale and other dangerous insect and fungus pests (*West Virginia Sta., 1904, pp. 96, figs. 16*).—An account of nursery inspection during the year under report is given by W. E. Rumsey (pp. 7-15).

A tabulated list of West Virginia nurseries is presented, with notes on their condition. The work along the line of orchard inspection is discussed by W. E. Rumsey and T. E. Brooks. This account includes a statement regarding the distribution of San José scale in country districts and in towns, spray mixtures for use in controlling this insect, and a brief résumé of the principal fruit sections of the State. The report also contains an account of spraying melons in the Ohio River Valley, by F. E. Brooks, and plant diseases of the State, by J. L. Sheldon.

Report on work done in 1904-5 in the control of San José scale and other dangerous insect and fungus pests (*West Virginia Sta. [1905], pp. 60, pls. 7*).—In the report for this year considerable attention is given to the grape curculio, which is discussed by F. E. Brooks. The same author also discusses nut weevils in West Virginia.

The report also contains a special report of the bacteriologist, J. L. Sheldon, on various plant diseases; potato blight, by A. L. Post; other investigations on potatoes, by T. C. Johnson; and a study of combined insecticides and fungicides, by B. H. Hite and C. H. Howard. Brief notes are also given as usual in these reports on nursery and orchard inspection.

Some points in nursery inspection, E. A. Popenoe (*Industrialist, 32 (1906), No. 18, pp. 275-279*).—The San José scale was the chief cause of the present nursery inspection laws in Kansas. A brief account is given of the methods employed in inspecting the nurseries, with particular reference to the more serious insect and fungus diseases. It is believed that not all of these diseases are transmitted in nursery stock. Apple-tree borers are apparently seldom carried in young nursery stock.

The plum curculio, F. Johnson and A. A. Girault (*U. S. Dept. Agr., Bur. Ent. Circ. 73, pp. 10, figs. 5*).—The life history and habits of this pest are described in detail.

The insect attacks plums, cherries, peaches, nectarines, apricots, apples, and pears, and sometimes feeds upon the foliage after the fruit has been harvested. The method of the attack upon various fruits is described and notes are given on the natural enemies of the pest. One of the most extensively applied remedies for the insects consists in the use of some form of jarring trap. This method has been widely adopted in plum and peach orchards in the South and has proved very satisfactory. The pest may be destroyed by thorough spraying with arsenicals. For this purpose arsenate of lead may be used at the rate of 2 lbs. to 50 gal. of water, or Paris green at the rate of 1 lb. to 150 to 200 gal. of water.

The codling moth in Arizona, J. J. Thornber (*Arizona Sta. Rpt. 1905, p. 22*).—The codling moth has been known in Arizona for 2 years and in infested districts causes wormy apples to the extent of 30 to 40 per cent. No hope is held out that this insect may be eradicated in Arizona, but it is believed that its presence will have an indirect benefit in forcing orchardists to spray their trees more thoroughly.

Report of committee on gypsy moth, insects, and birds, A. Pratt et al. (*Agr. of Mass., 52 (1904), pp. 217-239*).—A brief review is presented of the condition of the infested region contrasting the conditions observed in 1899 and 1904 in various towns in the neighborhood of Boston. A few new colonies have appeared outside the area which was known to be infested in 1899. In general the insect has spread slowly in various directions and in the localities of long infestation the numbers of the pests have greatly increased.

The brown-tail moth in Maine, E. F. HITCHINGS (*Bul. Maine Dept. Agr., 4 (1905), No. 4, pp. 101-127, pls. 4*).—A copy is presented of considerable correspondence relating to the prevalence of the brown-tail moth in Maine.

The Pomological Society of the State succeeded in getting an appropriation of $5,000 for 1905 and 1906 for the purpose of combating the brown-tail moth. In accordance with the act passed by the legislature a State entomologist was appointed to devote his time to the suppression of this and other insect and fungus pests. A review is given of the present status of the brown-tail moth in Maine. In many localities rewards have been offered for the destruction of the nests of this insect, and data regarding the amounts of money thus expended are presented in a tabular form.

The life history of the brown-tail moth is described and notes are given on other insect pests, including apple aphis, woolly aphis, scurfy bark-louse, and strawberry weevil, as well as on nursery inspection.

The goat moth and the wood leopard moth, R. S. MACDOUGALL (*Jour. Bd. Agr. [London], 12 (1905), No. 2, pp 115-118, fig. 1*).—Notes are given on the habits and life history of *Cossus ligniperda* and *Zeuzera æsculi*. Small branches infested with the leopard moth should be removed and burned, and the same remedies should be applied to trees infested with goat moth. The goat moth may be prevented to some extent from laying its eggs by painting the lower part of the tree with soft soap, kerosene, or some other substance obnoxious to the insect.

Woolly aphis, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt., 13 (1905), pp. 407-409, figs. 4*).—This pest is difficult to control on the more susceptible varieties of apples. A list is presented of apple varieties which appear to be more or less resistant to woolly aphis. The aerial form of the pest may be controlled by the use of kerosene emulsion or by fumigation with hydrocyanic-acid gas.

Leaf hoppers and their natural enemies, R. C. L. PERKINS and G. W. KIRKALDY (*Hawaiian Sugar Planters' Sta., Div. Ent. Bul. 1, pts. 9, pp. 267-479, pls. 12; 10, pp. 483-499, pls. 6; introduction, pp. XXXII+501-508, figs. 7*).—In continuation of this series (E. S. R., 17, p. 783) the general anatomical characters of leaf hoppers are described by G. W. Kirkaldy, in part 9, with notes on the rapidity of their multiplication, other points in their life history, and their classification. In the study of this group in the Hawaiian Islands and elsewhere various new species have been discovered and of many of these descriptions are given. Notes are also presented on the relations between leaf hoppers and ants. A bibliography of literature relating to leaf hoppers is appended to the bulletin.

Part 10 is supplementary to part 1 (E. S. R., 17, p. 477), and deals with observations made in Australia and Fiji Islands and material collected in those countries. A number of new species of Dryinidæ and Pipunculidæ are described.

In the introduction by R. C. L. Perkins, which is the last part received, a general account is presented of the work done in Australia, Fiji Islands, and the United States, with particular reference to the methods of transporting and handling parasites and also to the effects of these parasites upon the leaf hoppers. A brief summary of the bulletin is added, together with an index.

The pepper weevil, A. MERAZ (*Com. Par. Agr. [Mexico], Circ. 33, pp. 4, fig. 1*).—Peppers are subject to the attacks of *Anthonomus eugenii*. This pest was studied by the author, with particular reference to practical methods for controlling it.

It is recommended that peppers should not be planted on soil cultivated to Indian corn during the previous year. The selection of seeds from fruits which have resisted the attack of the insect is desirable on account of the fact that they possibly possess some resisting power. Infested fruits should be collected and destroyed as soon as they are recognized. Rotation of crops is also recommended. Some benefit may be derived on spraying with arsenicals, especially arsenate of lead.

The habits, life history, and means of combating Agrostis segetum, K. Rossikov (*Trudui Byuro Ent.* [*St. Petersb.*], *6* (*1905*), *No. 5, pp. 120, pls. 4, figs. 37*).—An elaborate review is presented of the appearance, distribution, and life history of this cutworm. The author discusses the number of generations, the egg, larva, and other stages of the pest. Attention is given also to its insect parasites belonging to various orders, with reference also to fungus and bacterial diseases. In the discussion of methods for controlling the pest the subject is discussed under different heads, according to the stage of the insect concerned.

The larva of Plodia interpunctella, B. Wahl (*Ztschr. Landw. Versuchsw. Oesterr.*, *8* (*1905*), *No. 10, pp. 950–954*).—This pest was found in fig coffee and also in a number of other food products. The systematic position of the moth is briefly outlined, and detailed notes are given on the external anatomy of the caterpillar, with particular reference to the number and location of the bristles.

Parthenogenesis in Otiorrhynchus turca, A. A. Ssilantjew (*Zool. Anz.*, *29* (*1905*), *No. 18, pp. 583–586, figs. 2*).—In studying this insect which has recently caused great damage to grapes in the region of the Black Sea, the author observed that no males were to be found. Observations along this line showed that females taken immediately after emergence and kept confined in glass jars during their whole life laid eggs which were perfectly fertile and developed into normal individuals.

On the Cecidomyid forming the galls or pseudocones on Pinus longifolia, E. P. Stebbing (*Indian Forester*, *31* (*1905*), *No. 8, pp. 429–434, pl. 1*).—For some time galls have been noticed on this pine tree which so closely resembled the cones as to be mistaken for them. When examined by the author they were found to be due to a species of Cecidomyia, which is briefly described. Notes are also given on a parasitic insect found upon the gall insect.

A new enemy of the Douglas fir, R. S. Macdougall (*Jour. Bd. Agr.* [*London*], *12* (*1906*), *No. 10, pp. 615–621, figs. 4*).—*Megastigmus spermotrophus* was found infesting the seeds of Douglas fir.

This insect is described in its various stages. The eggs are laid in the young cones of the Douglas fir and each seed is infested by one larva. In preventing the destruction of cones by this pest it is recommended that after the seed is collected it should be subjected to treatment of bisulphid of carbon at the rate of 1 oz. for every 50 cu. ft. of air space.

Notes on termites with special reference to the destruction of timber by Calotermes brouni, T. Broun (*New Zeal. Dept. Agr. Ann. Rpt.*, *13* (*1905*), *pp. 430–436, pls. 2*).—It has been found that for railroad ties various woods may safely be used which would otherwise soon be destroyed by white ants. This is due to the fact that the ants are frightened away by the jar produced by passing trains.

Calotermes brouni is an exceedingly injurious species, and notes are given on its injury to various kinds of wood, especially Puriri and Kauri woods. The insect is described in its various stages.

Spraying apples. Relative merits of liquid and dust applications, C. S. Crandall (*Illinois Sta. Bul. 106, pp. 205–242, figs. 14*).—While a combination of Bordeaux mixture and arsenicals has long been known to give satisfactory results in the control of scab and some of the other common fungus diseases of apples, as well as codling moth and leaf-eating caterpillars, the method is somewhat extensive and various experiments have been made to test the economy of dust sprays.

The author's work along this line has been carried on for a period of 3 years, during which various plats of apple trees were sprayed or dusted from 3 to 8 times during the season, the first application being made just as the buds were opening. Particular attention was given during this series of experiments to the effect of treatment on apple scab, fruit blotch, codling moth, and curculio. It appears from these experiments that the pests just mentioned must be recognized as of a permanent nature and

that they require annual treatment in order to secure a good crop of clean fruit. The use of a dust spray considerably diminishes the cost and labor of spraying, but it is quite inefficient.

Trees sprayed with liquid Bordeaux mixture and Paris green retained their foliage through the season, while the foliage turned yellow and fell off from the trees treated with a dust mixture as readily as from the check trees. This loss of foliage is an important matter in the growth of the tree and indicates clearly that the dust method is not satisfactory. The dust spray is 52 per cent cheaper than the liquid spray but, according to the author, has no other advantages. It is, therefore, recommended that the orchardist spend his time and energy in perfecting his methods of preparation and application of Bordeaux mixtures combined with arsenicals.

In these experiments the formula used for the liquid Bordeaux mixture was 4 lbs. copper sulphate, 4 lbs. of lime, ¼ lb. Paris green per 50 gal. of water, and a proprietary form of Bordeaux and Paris green was used for the purpose of comparison.

Spraying, G. F. WARREN (*New Jersey Stas. Bul. 194, pp. 60*).—The purpose of the author was to combine in the present bulletin in a convenient form the various recommendations which have been made by the station in previous publications regarding the control of insects and fungus diseases. The bulletin constitutes a convenient summary of information on this subject and contains an account of the purpose of spraying, the methods to be adopted in spraying various fruit and garden crops, a spray calendar, formulas for the preparation of the more important fungicides and insecticides, and a discussion of spray pumps.

Spray calendar (*Vermont Sta. Spec. Bul., Apr., 1906, folio*).—Formulas are given for the preparation of lime-sulphur-salt wash, Paris green, Bordeaux mixture, Hellebore, and kerosene emulsion, and brief directions are given for the application of these remedies.

The preparation of emulsions of crude petroleum, T. M. PRICE (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 89, pp. 4*).—The ordinary kerosene emulsion is not well adapted for use as a dip or hand treatment for animals, since the oil does not remain emulsified and is distributed unevenly on the surface of the body.

Beaumont oil has been found by the Bureau to be an effective dip for destroying cattle ticks. There are certain objections to its use, however, particularly an occasional injury to cattle. Experiments were therefore made to secure an emulsion which would remain uniform for an indefinite period. This was accomplished by employing a formula calling for 2 gal. crude petroleum, ½ gal. water, and ½ lb. hard soap. The soap is dissolved in hot water and the crude petroleum is added and mixed with a spray pump, after which it is diluted with the desired amount of water.

An emulsion of crude petroleum made in this way remains fluid indefinitely without any tendency to a separation of oil and water. Brief directions are also given for the preparation of emulsions and other oils.

The fumigation of dwelling houses for vermin, C. FULLER (*Natal Agr. Jour. and Min. Rec., 8 (1905), No. 5, pp. 457–464, fig. 1*).—Directions are given for the use of hydrocyanic-acid gas in destroying bedbugs, cockroaches, and other insects in houses. For large rooms several generators may be arranged, and care should be exercised to prevent one of them from being set in operation before the others if the attendant is still in the room. It is recommended that the period of fumigation be 6 to 8 hours if possible, but never less than 3 hours.

Key to the known larvæ of the mosquitoes of the United States, H. G. DYAR (*U. S. Dept. Agr., Bur. Ent. Circ. 72, pp. 6, fig. 1*).—This circular contains an analytical key intended for use in the identification of the known larvæ of mosquitoes.

House flies, L. O. HOWARD (*U. S. Dept. Agr., Bur. Ent. Circ. 71, pp. 9, figs. 9*).—This is a revision of Circular 35 (E. S. R., 10, p. 654).

The distribution of tsetse flies in French East Africa and in Kongo, A. LAVERAN (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 23, pp. 929–932*).—Brief

notes are given on the distribution of various species of Glossina and Tabanus in Senegal, French Kongo, New Anvers, the district of Ubangi, and other neighboring countries.

The horse botfly (*Jour. Bd. Agr. [London], 12 (1905), No. 2, pp. 108-110, figs. 2*).—The botfly is quite common in the central and southern part of England, but almost entirely absent from the northern part of the country. The common species observed in England is *Gastrophilus equi*, but it is considered desirable that the point should be determined whether other species also occur.

Observations on the bionomics of Auchmeromyia leuteola, F. C. WELLMAN (*Ent. News, 17 (1906), No. 2, pp. 64-67, figs. 3*).—The larvæ of this fly is a blood-sucking maggot which has previously been referred to from South Africa. The author followed the complete life history of the species and gives notes on its method of attacking man.

Anatomy of Boophilus annulatus, S. R. WILLIAMS (*Proc. Boston Soc. Nat. Hist., 32, No. 8, pp. 313-334, pls. 5, figs. 3*).—The external anatomy, habits, and life history of the cattle tick have been quite thoroughly worked out. The present article, however, is apparently the first attempt to describe in detail the various features of the internal anatomy of the cattle tick.

It appears that the internal anatomy of this pest differs decidedly from that of *Ixodes ricinus* described in 1861 by Pagenstecher. In order to study the internal anatomy of cattle ticks it was found necessary to allow the body to shrink somewhat in alcohol. This makes it possible to remove the chitin which otherwise interferes with making sections. According to the author, the external porous areas on cattle ticks are sense organs. The alimentary canal is a slightly curved tube provided with 6 large diverticula, which occupy most of the body of the tick. The adult females appear to eject nothing from the alimentary canal or the renal organs.

Apiculture, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt., 13 (1905), pp. 403-405, pls. 4*).—On account of the growing importance of the bee industry in New Zealand, it is recommended that an efficient expert be appointed for the purpose of giving instruction to bee raisers. The author has inspected about 2,500 colonies of bees, and brief notes are presented on foul brood, bee moth, and other troubles which affect the bee raiser.

Beekeeping: How to meet its dangers and difficulties, B. N. GATES (*Agr. of Mass., 52 (1904), pp. 411-426*).—Statistics are given on the amount of honey produced in Massachusetts and certain other States with which Massachusetts is compared. In wintering bees it is essential that the colonies have plenty of stores and be given a uniform temperature, without too much moisture. Particular attention is given to the discussion of the bee moth, robbing, foul brood, and other diseases of bees.

Scientific queen raising, A. H. W. CLARKSON (*Queensland Agr. Jour., 16 (1905), No. 1, pp. 118-122*).—The author argues that it is useless to attempt to rear queens in weak colonies. The nuclei should be strong, since otherwise the necessary amount of food and the proper temperature can not be secured for the development of queens. As a standard for good queens it is considered that they should be able to lay from 2,000 to 3,000 eggs per day during the proper season of the year.

The method recommended by the author consists in transferring a frame of queen cells with royal jelly to a strong colony of bees which, at the time, is working vigorously in the upper part of the hive. Before this is done a couple of frames containing young larvæ could be removed from the lower to the upper story and a queen placed between the bottom and top story. As soon as the bees find that the brood is not increasing in the top story they proceed to raise a new queen.

Ventilation of bees, DEVAUCHELLE (*Apiculteur, 50 (1906), No. 1, pp. 10-14*).—The author presents a discussion of the phenomenon of bees ventilating the hive by wing movements at the entrance to the hive. It is believed that the purpose of this is to lower the temperature in the hive and renew the air in order to increase the evaporation of nectar.

Bees and the color of flowers, G. BONNIER (*Compt. Rend. Acad. Sci.* [*Paris*], *141* (*1905*), *No. 24, pp. 988–994*).—After carrying on numerous observations with regard to the attraction of the color of flowers for bees, the author comes to the conclusion that the color of flowers does not exercise any apparent influence upon the worker bee.

Catalogue of the exhibit of economic entomology at the Lewis and Clark Centennial Exposition, Portland, Oregon, 1905, R. P. CURRIE (*U. S. Dept. Agr., Bur. Ent. Bul. 53, pp. 127*).—This catalogue was designed to increase the usefulness of the exhibit of the Bureau of Entomology in Portland by furnishing information regarding the insects contained in that exhibit. The species represented were largely the same as those shown at the St. Louis Fair, but some insects of interest only to eastern localities were omitted.

FOODS—HUMAN NUTRITION.

Standards of purity for food products (*U. S. Dept. Agr., Office Sec. Circ. 17, pp. 7*).—The food materials for which standards are proposed include dried, evaporated, canned, and preserved fruits and similar products, flavoring extracts, oils used in the preparation of extracts, olive oil, cotton-seed oil, and other edible vegetable oils, and table salt.

A flavoring extract is defined as "a solution in ethyl alcohol of proper strength of the sapid and odorous principles derived from an aromatic plant, or parts of the plant, with or without its coloring matter, and conforms in name to the plant used in its preparation."

The various flavoring extracts described are intended solely for food purposes and, it is pointed out, are not to be confounded with similar preparations described in the Pharmacopœia for medicinal purposes.

This publication supplements a circular previously noted (E. S. R., 16, p. 894).

Legislation regulating the sale of foods (*Rev. Soc. Sci. Hyg. Aliment., 2* (*1905*), *No. 6, pp. 467–640*).—A summary of laws regarding the regulation of foods, previously noted, is continued (E. S. R., 17, p. 59). The present installment includes Holland, Spain, Portugal, Sweden, Denmark, France, and the United States.

The microscopy of vegetable foods, A. L. WINTON (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1906, pp. XVI + 701, figs. 589*).—This volume, which was prepared with the collaboration of J. Moeller, summarizes the results of a large number of original investigations on the histology of products of vegetable origin, and is designed for the use of food analysts, agricultural chemists, pharmacists, and others engaged in the examination of foods, as well as the physician who may be called upon to identify vegetable substances in stomach contents and feces.

It has been the author's aim to make the volume comprehensive and to have it cover the important vegetable foods used by man and domestic animals, and to present the material in such form that it will be available for ready reference. In preparing the work the author states that leading authorities have been consulted and "credit has frequently been given for important discoveries, although so far as possible the writer has based his descriptions on his own observations." Laboratory equipment, methods, and general principles relating to the microscopical examination of vegetable food products are discussed.

The materials described and illustrated include grain and its products and impurities, oil seeds and oil cakes, legumes, nuts, fruit and fruit products, vegetables, alkaloidal products and their substitutes, spices and condiments, and commercial starches. The illustrations, very many of them from original drawings, are a special feature of the volume and add much to its value. A bibliography, glossary, and index are included. The volume as a whole is an important contribution to the subject of vegetable histology, which, both as a pure and applied science, has hitherto been taken up almost exclusively by European investigators.

Food products, A. L. WINTON ET AL. (*Connecticut State Sta. Rpt. 1905, pt. 2, pp. 107-144*).—Under the provisions of the State pure-food law 1,347 samples of milk, olive oil and substitutes, coffee, spices, chocolate, candies, jams, extracts, and similar products were examined, over half of the samples being collected by the station and the remainder submitted by the dairy commissioners and by health officers, consumers, and dealers. Of these samples 388 were adulterated or below the standard, 94 were compounds, while the remaining 865 were not found to be adulterated.

Cereal breakfast foods, C. D. WOODS and H. SNYDER (*U. S. Dept. Agr., Farmers' Bul. 249, pp. 36*).—The results of investigations carried on at a number of experiment stations on the digestibility and nutritive value of cereal breakfast foods are summarized, as well as general information on this important class of food products. Some of the questions discussed are the preparation of modern cereal breakfast foods, predigested and malted goods, cooking, the absorption of water by different cereals and their solubility, cost of cereal breakfast foods as compared with other foods, and the place of these foods in the diet. Information regarding the use of cereal products as coffee substitutes is also summarized.

"In the selection of cereal breakfast foods the consumer may be guided by the results of analyses of disinterested chemists, by the digestibility as determined by actual tests, by cost, by taste, by economy, or by the observed effects of the goods upon individuals. It seems fair to conclude that the chemical composition, considered in connection with digestibility and cost, furnishes a satisfactory guide for selection, due attention being paid to palatability and individual preferences.

"All things considered the cereal breakfast foods as a class are nutritious, convenient, and reasonably economical foods and worthy of an important place in the diet when judiciously combined with other foods."

Food and the principles of dietetics, R. HUTCHISON (*London: Edward Arnold, 1906, pp. 582; rev. in Brit. Med. Jour., 1906, No. 2362, p. 806*).—This handbook has been revised and some new material added, including among other topics a discussion of underfeeding.

Unpolished rice, H. S. CLUBB (*Philadelphia: Vegetarian Society of America, 1905, pp. 32*).—On account of its higher protein content the use of unpolished instead of polished rice is advocated. In addition to discussing the various topics connected with the use of rice in the diet the author has summarized a large number of recipes for preparing it for the table.

The digestibility of flour made from legumes, M. WINTGEN (*Veröffentl. Mil. Sanitätsw., 1905, No. 29, pp. 37-55; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 4, pp. 225, 226*).—Artificial and natural digestion experiments with pea meal, bean meal, and lentil meal are reported. As shown by the experiments with man the pea meal was more digestible than the other sorts studied.

Preserved eggs and egg substitutes, A. BEYTHIEN and L. WATERS (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 5, pp. 272-274*).—Data are reported regarding the composition of egg powders and similar goods.

Chemical change produced in foods, etc. (*Pure Products, 2 (1906), Nos. 2, pp. 70-72; 3, pp. 118-120*).—A summary of data regarding the chemical changes due to micro-organisms, etc., which take place when food of different sorts is stored or preserved in different ways.

Preserved fruits in lacquered tins (*Lancet [London], 1906, I, No. 8, pp. 529, 530*).—Examination of fruits in tin cans with the interior surface lacquered showed that this method of treating the can prevented metallic contamination.

A number of experiments were made with this method of canning, using raspberries, strawberries, gooseberries, plums, blackberries, greengages, and damsons. "In no instance was there the least indication of any action on the tin and not a trace of tin could be found in the sirup, while the color of the fruit was satisfactorily preserved."

Pure British dried vegetables (*Lancet [London], 1906, I, No. 11, p. 766*).—Commercial dried or evaporated vegetables are described, which are regarded as of good quality. It is stated that the condition of the food constituents was not changed by evaporation, the albumins of the dried product being still soluble. Color and freshness of flavor, it is stated, were also little affected.

The occurrence of esters in bananas, F. ROTHENBACH and L. EBERLEIN (*Deut. Essigindus., 1905, No. 9, pp. 81, 82; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 4, pp. 230, 231*).—The authors report isovaleric-isoamyl ester and ethyl ester in bananas. The possible occurrence of amyl acetate is also noted. Experiments showed that ester formation did not depend upon micro-organisms, but was a product of cell activity.

Commercial extract of lemon, A. MCGILL (*Lab. Inland Rev. Dept. [Canada], Bul. 114, pp. 15*).—Considerable range in alcohol strength and in lemon oil content was noted. Of the 110 samples examined, 2 contained 6 per cent or more of lemon oil and 78 less than 1 per cent. No methyl alcohol was found.

Coffees without caffein, G. BERTRAND (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 3, pp. 209–211*).—According to the author's analyses, the berries of *Coffea gallienii, C. bonnieri, C. mogeneti,* and *C. humblotiana* contain no caffein. The ash, water, and total nitrogen in the samples were also determined. A sample of *C. mauritiana* contained only a very small percentage of caffein, namely, 0.7 gm. per kilogram. A sample of *C. arabica*, analyzed at the same time, showed 13.4 gm. caffein per kilogram.

Maple sugar and sirup, W. F. HUBBARD (*U. S. Dept. Agr., Farmers' Bul. 252, pp. 36, figs. 9*).—This bulletin is based on a publication of the Bureau of Forestry previously noted (E. S. R., 17, pp. 774, 790).

Physiological studies of vegetarian diet, W. CASPARI (*Arch. Physiol. [Pflüger], 109 (1905), No. 11–12, pp. 473–595, pls. 3*).—Extended studies are reported of vegetarian and raw fruitarian diet. In connection with this work studies were made of the metabolism of nitrogen, the digestibility of the diet, and the effect of the food on the respiratory quotient. Two of the subjects were professional athletes, one a vegetarian, the other not. The general conclusions drawn were in effect as follows:

A strictly vegetable diet, even when made up of raw foods, is able to nourish the body in youth and maintain it at the highest degree of physical strength and mental and physical power, yet this sort of diet is considered unsatisfactory because the nutrients, particularly protein, are not well assimilated because the food is lacking in flavor and is of large volume. The vegetarian diet when made up of ordinary vegetables, fruits, etc., has an advantage in that it is not expensive.

It did not appear that the vegetarian diet surpassed the ordinary diet on account of the small amount of uric acid formed. As is commonly claimed the amount of purin bodies formed was small as compared with the quantity obtained with an excessive meat diet and under certain pathological conditions. As regards the performance of muscular work the vegetarian diet certainly is not superior to the ordinary mixed diet.

A respiration calorimeter with appliances for the direct determination of oxygen, W. O. ATWATER and F. G. BENEDICT (*Washington, D. C.: Carnegie Institution of Washington, 1905, pp. X+193, figs. 49*).—This volume includes a detailed description of a respiration calorimeter and accessory apparatus which the authors have devised for experiments with man, together with the results of check experiments to determine the accuracy of the apparatus and an experiment with man.

The respiration calorimeter has been in process of development for 12 years, and much of the work connected with it has been a part of the cooperative nutrition investigations of the Department of Agriculture and reported in Department publications (E. S. R., 15, p. 698; 17, p. 165). Under the auspices of the Carnegie Institu-

tion very important changes in the apparatus have been introduced and the method of experimenting has been modified to include the direct determination of oxygen. A quantity of air circulates through the apparatus and the carbon dioxid and water eliminated in the respiratory products are removed by passing the air current through soda-lime mixture and through sulphuric acid. As the air current passes back into the respiration chamber oxygen is added to make up for that used by the subject, the amount being determined by weighing the cylinder containing the oxygen before and after the addition is made.

The calorimeter may be fairly designated an instrument of precision and serves for the very accurate measurement of energy, carbon dioxid, water, and oxygen in experiments with man extending over a number of days, under various conditions of work and rest.

In connection with the experiments, the balance of income and outgo of nitrogen and other food constituents is taken into account so that the experiments furnish data for considering the total income and outgo of matter and energy in addition to the respiratory quotient.

"In experiments with man as carried out with this apparatus and accessories, the following determinations of intake and output of material are made:

"The intake [as regards matter] consists of food, drink, and oxygen from respired air. The amounts are determined by weighing. The analyses include determinations of water, ash, nitrogen, carbon, hydrogen (organic), and at times sulphur and phosphorus. The output of material consists of products of respiration and perspiration, urine, and feces. The dry matter of feces and urine is subjected to a series of analyses similar to those for food, and the water and carbon dioxid of perspiration and respiration are determined according to the methods discussed in this report. The determinations of nitrogen in perspiration are made, when necessary. . . .

"[In the case of energy] the intake is derived from the potential energy, i. e., heats of combustion of the food. The output consists of sensible heat given off from the body, the latent heat of the water vaporized, and the potential energy, i. e., heat of combustion of the unoxidized portions of the dry matter of urine and feces. In certain cases, e. g., work experiments, a not inconsiderable portion of the output is in the heat equivalent of external muscular work. . . .

"The heats of oxidation are determined by burning the substances in the bomb calorimeter; the heat given off from the body is measured by the respiration calorimeter; the external work is measured by a specially devised ergometer. Allowance is made for heat introduced and removed by the ventilating air current, food, feces, and urine, and for that involved in changes of body temperature, which is also measured. . . .

"Since the completion of the new apparatus, 22 experiments with 5 different subjects, covering a total of 60 days, have been conducted. These experiments lasted from 1 to 13 days, during which time the subject remained inclosed in the calorimeter chamber. Ordinarily the experiment lasts 3 or 4 days. In general, each experiment is preceded by a preliminary period outside the chamber, during which the subject is given the special diet to be tested, and his habits of life so modified as to conform with those to be followed in the chamber. When the subject is to be engaged in muscular work, he devotes considerable time in the preliminary days to riding a bicycle in the open air, the amount of work performed being as nearly as can be judged equivalent to that to be done later on the bicycle ergometer inside the chamber.

"The food for the whole experimental period, including the preliminary days, is carefully weighed, sampled, and daily portions placed in proper containers ready for consumption. The more easily decomposed materials, such as milk and cream, are sampled, weighed, and analyzed each day. The bread and meat when used are

33747—No. 11—06——6

carefully sterilized in glass jars. The diet may be so planned as to maintain a uniform quantity of nitrogen and a constant calorific value from day to day."

Respiratory quotient in static work, II, A. BORNSTEIN and A. OTT (*Arch. Physiol. [Pflüger], 109 (1905), No. 11-12, pp. 621-627*).—On an average of 17 experiments it was found that the work required in standing was equivalent to 156 calories per minute. Data are also given regarding the expenditure of energy when a pack was carried on the back.

Respiratory quotient in static work, III, A. BORNSTEIN and B. VON GARTZEN (*Arch. Physiol. [Pflüger], 109 (1905), No. 11-12, pp. 628-633*).—The data reported have to do with the effect of weighting the chest on the oxygen consumed and the carbon dioxid excreted.

Alcohol, sugar, and caffein, and their effect upon muscular work, I. IOTEYKO (*Rev. Soc. Sci. Hyg. Aliment., 2 (1905), No. 5, pp. 483-491, fig. 1*).—From experiments in which musular work was measured with an ergograph, the conclusion was reached that sugar is an excellent food, a direct source of energy in the muscles, and not an excitant. Caffein is considered as an excitant of the nervous system and, in the author's opinion, is of great importance as a tonic, though it has probably no nutritive value.

The after effect of muscular work upon water vapor secretion, H. WOLPERT and F. PETERS (*Arch. Hyg., 55 (1906), No. 3, pp. 309-322*).—The increased excretion of water vapor due to muscular work can be noted for several hours after the work has ceased.

The daily curve of water vapor excretion in man, H. WOLPERT and F. PETERS (*Arch. Hyg., 55 (1906), No. 3, pp. 299-308, dgm. 1*).—From their investigations the authors conclude that neither the time of day nor the diet is a direct cause of variation in the amount of water vapor excreted. The average amount excreted per day was 1,650 gm. at, in still air, a temperature of 24° C. and containing 65 per cent moisture.

Observations on creatin excretion in man, C. J. C. VAN HOOGENHUYZE and H. VERPLOEGH (*Ztschr. Physiol. Chem., 46 (1905), No. 5-6, pp. 415-471, figs. 8*).—In the experiments reported muscular work did not exercise any marked effect on the excretion of creatin except in the case of a fasting subject, when an increase was noticeable. Gelatin and casein added to the ration did not increase creatin excretion, and the addition of 5 eggs caused only a slight increase. Other questions relating to creatin formation and excretion were also studied and the investigation as a whole is discussed with reference to Folin's theory of nitrogen metabolism.

Report of the departmental committee on vagrancy, J. L. WHARTON ET AL. (*London: Wyman & Sons, Ltd., 1906, pp. VI + 123*).—The housing, care, and management of vagrants, and their relation toward other classes are considered, one of the questions taken up being the dietary for casual wards and labor colonies. The dietary recommended for casual wards would cost about 39 cts. per head per week and would furnish 63 gm. protein and 2,500 calories per head per day, and that recommended for labor colonies would cost about 33 cts. per head per week and furnish 66 gm. protein and 2,236 calories per head per day.

ANIMAL PRODUCTION.

Commercial feeding stuffs, E. H. JENKINS and A. L. WINTON (*Connecticut State Sta. Rpt. 1905, pt. 3, pp. 145-188*).—The feeding stuffs examined under the State law included cotton-seed meal, linseed meal, rape-seed meal, wheat bran, wheat middlings, wheat mixed feed, maize meal, gluten meal and feed, hominy feed, rye feed, malt sprouts, dried distillery grains, buckwheat middlings, alfalfa meal, miscellaneous mixed feeds, proprietary horse feeds, proprietary and other dairy and stock feeds, proprietary poultry feeds, beef scrap, and meat meal.

"The examinations of these feeds show that in many cases the dealers do not give the guaranties, as required by law. When given, they are too often misleading, being much higher than the composition of the goods warrants. This is especially noticeable in the gluten meals and gluten feeds.

"The mixtures of wheat feed and corncobs, formerly sold, illegally, as 'wheat feed,' are now sold under distinctive names and with a guaranty; thus complying with the law.

"There are still on the market a large number of low-grade mixed feeds, of very moderate feeding value, but sold for only a few dollars per ton less than the standard high-grade feeds."

In most cases a feeder can not use to advantage any boughten feed containing less than 15 per cent of protein.

"Ready-mixed feeds, made of a number of by-products or factory wastes, may wisely be let alone, unless the buyer can see for himself out of just what raw material the mixture is being prepared. Low grade, damaged corn, shriveled wheat, peanut refuse and wheat screenings containing many weed seeds, are not infrequently found in such feeds by careful examination, but are not easy for the buyer himself to recognize."

Commercial feeding stuffs sold in Maryland, H. B. McDonnell et al. (*Md. Agr. Col. Quart., 1905, No. 30, pp. 7*).—The protein and fat were determined under the State feeding-stuff law in a number of samples of meat meal and other poultry feeds of animal origin, cotton-seed meal, linseed meal, unpressed flaxseed meal, gluten feed, molasses grains, wheat middlings, alfalfa meal, short-cut alfalfa, dried distillers' grains, wheat bran, wheat middlings, proprietary poultry feeds, pigeon feed, ground oats, sugar-beet pulp feeds, corn bran, and mixed and proprietary feeds. "We have reason to believe that ground peanut hulls are being used to some extent to adulterate feeds, probably bran, and purchasers should be on the lookout for this, as the hulls are worthless as a feed."

Concentrated feeding stuffs, J. P. Street, W. P. Allen, and V. J. Carberry (*New Jersey Stas. Bul. 193, pp. 38*).—The feeding stuffs examined under the State pure-food law included cotton-seed meal, linseed meal (old process), germ meal, gluten feed, corn bran, hominy meal and similar goods, distillers' and brewers' grains, malt sprouts, molasses grains, mixed and proprietary feeds, biscuit refuse, biscuit refuse and milk, alfalfa meal, barley feed, dried sugar beet pulp, meat meal and proprietary poultry feeds, calf meal, wheat bran, wheat middlings, feeding flour, wheat feed, rye bran, rye feed, corn meal, corn-and-cob meal, mixed ground grains, buckwheat middlings, buckwheat bran, and buckwheat feed.

"Of the 125 different brands of feed received, and which should have been guaranteed, four failed to meet this requirement.

"Of the 241 samples which were guaranteed, 90 were deficient, 71 of these being low in protein.

"Of the 103 samples which did not require a guarantee, all were pure products, but the wheat brans and feeding flours were below normal quality.

"No direct adulteration is reported, but there are a number of feeds on the market whose composition does not warrant the high guarantees they carry.

"The purchaser of protein will rarely find any feed containing less than 15 per cent of protein a desirable or an economical purchase, and in all cases a strict regard must be given to the amount of nutrients guaranteed and the prices asked for the same."

Third report on concentrated feeding stuffs and cotton-seed meal, B. W. Kilgore, C. D. Harris, and J. C. Phelps (*Bul. N. C. Dept. Agr., 26 (1905), No. 11, pp. 63, figs. 7*).—Under the provisions of the State feeding-stuff law 534 samples of wheat bran, wheat middlings, bran and shorts, ship stuff, oat feeds, corn and oat feeds, rice meal, rice feed, peanut bran, peanut feed, molasses or sugar feeds, malt sprouts, gluten feed, hominy feeds and chops, cotton-seed meal, cotton-seed hulls, cotton-seed feeds, and mixed and proprietary feeds.

About one-third of the samples of wheat bran were found to contain corn bran, rice chaff, and peanut shells. One-third of the samples of bran and shorts were also found to be mixtures. In the case of corn and oat feeds, molasses feeds, hominy feeds, cotton-seed feeds, and mixed and proprietary feeds most of the samples were of good quality. In the case of other classes of goods analyzed a larger proportion of the goods were below the standard. "Good grades of cotton-seed meal contain 43 per cent or more of protein. This means that they have about 7 per cent of nitrogen, which is equal to 8.5 per cent of ammonia. Meals in past years especially have not infrequently been considerably higher than this." Of the 120 samples examined 37 were below the standard, 7.5 per cent ammonia.

Commercial feeding stuffs, J. L. Hills, C. H. Jones, and F. M. Hollister (*Vermont Sta. Bul. 117, pp. 8*).—Some 150 samples of commercial feeding stuffs were collected for examination under the State law in the spring of 1905. These included cotton-seed meal, linseed meal, gluten meals and feeds, distillers' dried grains, oat feeds, corn and oat feeds, hominy feed, sugar feed, ground beef scraps, wheat offals, and provenders.

Commercial feeding stuffs, J. L. Hills and C. H. Jones (*Vermont Sta. Bul. 118, pp. 9–16*).—In the autumn of 1905, 270 samples of commercial feeding stuffs were collected for inspection under the State law, including cotton-seed meal, linseed meal, gluten meals and feeds, distillers' dried grains, oat feeds, corn and oat feeds and similar goods, hominy feeds, mixed feeds, molasses grains, molasses beet pulp, alfalfa meal, calf meal, provenders, and wheat offals. The cotton-seed meals contained 41.5 per cent protein as compared with 44 per cent found in the samples on sale in the State up to a year or two ago. A low protein content has been observed elsewhere and has been attributed to general crop conditions.

Olive pomace as a feeding stuff, E. Marchi (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 163–172*).—From a study of the composition of olive pulp and a summary of data regarding its feeding value, the conclusion is reached that this material can be used in the feeding of farm animals, but that it should be mixed with some material which is low in fat and carbohydrates, such as legumes, commercial by-products, skim milk, casein, dried blood, etc.

Adulteration of feeding stuffs, C. Gotusso (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 205–209*).—Work connected with feeding-stuff inspection in Italy is spoken of. The author believes that chemical analysis furnishes a satisfactory basis for such work.

Alfalfa for the growing and fattening of animals in the Great Plains region, I. D. Graham (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 86, pp. 242–267*).—This is reprinted from the annual report of the Bureau for 1904 (E. S. R., 17, p. 686).

The effect of the ration on the value of the manure, J. M. Bartlett (*Maine Sta. Bul. 126, pp. 45–48*).—In digestion experiments with steers the potash and phosphoric acid in the excretory products were determined, as well as the nitrogen. The rations were made up of hay alone and with spring and winter wheat bran and cotton-seed meal. The following table summarizes the values found:

The money value of the fertilizing elements excreted on each ration and per 100 lbs. of each feed.

Ration.	Nitrogen.	Phosphoric acid.	Potash.	Total value.
	Cents	*Cents.*	*Cents.*	*Cents.*
Hay alone	5.36	0.39	2.98	8.63
Hay and spring wheat bran	10.40	2.03	3.95	16.38
Hay and winter wheat bran	9.52	1.67	3.70	14.89
Hay and cottonseed meal	15.30	1.32	3.95	20.57
100 lbs. hay	13.50	.98	7.45	21.93
100 lbs. spring wheat bran	37.80	11.91	8.93	58.64
100 lbs. winter wheat bran	31.90	8.85	7.27	48.02
100 lbs. cottonseed meal	99 40	9.30	9.60	118.30

"In the first experiment with hay alone, more nitrogen was found in the excretions than was taken in the food. This discrepancy was probably due to insufficient nitrogen in the ration to maintain the animals and they lost flesh, excreting some body nitrogen. . . .

"The larger part of the nitrogen, the most expensive element, and potash are given off in the urine, hence the importance of saving all of this most valuable part of the manure. Not only are other elements found in large quantities in the liquid, but they are in much more available form than in the solid. Only traces of phosphoric acid were found in the urine."

The nitrogen balance in the nutrition of ruminants, A. GOUIN and P. ANDOUARD (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 122-124*).—Data are reported regarding the proportion of nitrogen excreted in the urine and feces. The authors believe that such data should be used with caution, especially when it is remembered that the food material remains a long time in the digestive tract of Herbivora.

Concerning the assimilation of protein in the animal body, E. ABDERHALDEN and F. SAMUELY (*Ztschr. Physiol. Chem., 46 (1905), No. 1-2, pp. 193-200*).—The examination of the blood of horses under different conditions showed that the protein of food was without influence on the composition of serum proteid.

The nutritive value of amids, B. VON STRUSIEWICZ (*Ztschr. Biol., 47 (1905), p. 143*).—From experiments with sheep the author concludes that amids have the same value as proteids, a deduction not in accord with the consensus of opinion of other investigators.

Phosphates in the ration of young animals, RASQUIN (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 62-68*).—The work of other investigators is summarized and tests briefly reported in which rations with and without added phosphate (ground bone) were studied with chickens. On a powdered bone ration the gain in weight was greater and the skeleton was heavier and contained a larger amount of lime and phosphoric acid. Mineral phosphates, the author concludes, are of value in the feeding of young animals.

Watering farm animals, P. WERY (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 86-91*).—Various questions concerned with the wholesomeness of the water supply are taken up. The author recommends that more public watering troughs be provided which will give a constant supply of water of good quality.

Proceedings of Second International Congress for the Rational Feeding of Farm Animals (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Compt. Rend., pp. 192*).—The programmes, list of members, proceedings, etc., of the Second International Congress for the Rational Feeding of Farm Animals, which was held in 1905 at the Universal Exposition at Liège.

Résumé of the principal experiments on cattle feeding which have been carried on in the low countries, J. J. O. DE VRIES (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 149-162*).—Dutch investigations on cattle feeding are summarized. The author believes that rations which have given satisfactory results in practice should be studied by scientific methods.

Feeding experiments with cattle designed for fattening and pasture, L. BAUWENS (*2. Cong. Internat. Aliment Ration. Bétail, 1905, Raps., pp. 144-148*).—Belgian studies are summarized comparing horse beans with and without other concentrated feed for young cattle, but conclusions are not drawn.

. **Experiments on fattening calves,** F. SMEYERS (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 197-204*).—The tests reported show that feeding whole milk to calves is not profitable.

Data are summarized regarding skim milk supplemented by other feeds, and attention is directed to the bad results which were obtained in the feeding of sour milk. The author believes that the question of the better utilization of skim milk

should be studied and that the degree of acidity which may be permitted without harm should be determined.

Cost of maintenance and growth of ruminants, A. GOUIN and P. ANDOUARD (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 115-121*).—On the basis of experimental evidence, the authors conclude that the energy required for a kilogram of gain in body weight is about 1,200 calories per square meter surface area. Powdered bone is considered an important aid in practical feeding.

Western feeds for beef production, J. G. HANEY and O. H. ELLING (*Kansas Sta. Bul. 132, pp. 21-52, figs. 9*).—Using 64 grade Shorthorn and Hereford cattle divided into 8 uniform lots, the value of corn-and-cob meal and Kafir corn meal with alfalfa hay, with Kafir corn hay, and with sorghum hay was studied, as well as ground wheat with alfalfa hay, and a mixed ration containing all the other feeding stuffs enumerated.

The greatest gain in the 152 days of the test, 338 lbs., was noted with the lot fed corn-and-cob meal and alfalfa hay, and the smallest gain, 160 lbs., with the lot fed ground Kafir corn and sorghum hay. Generally speaking, the lots fed the rations containing alfalfa hay and the mixed ration made larger gains than the other lots.

The cost of a pound of gain ranged from 5.13 cts. with the corn-and-cob meal and alfalfa hay ration to 11.74 cts. on ground Kafir corn and sorghum hay.

In the case of the lots fed ground grain and alfalfa hay the dressed weight was on an average 60 per cent of the live weight in round numbers. In the case of the other lots it was somewhat lower. Other data regarding the slaughter test are recorded.

"For beef production, ground Kafir corn is about equal, pound for pound, to corn-and-cob meal when alfalfa hay is fed with either of these concentrates. . . . Ground wheat and alfalfa hay, fed together, is not an economical ration for beef on account of the loosening effect of these feeds on the steers and the expensiveness of the wheat. . . .

"A matter of this experiment of considerable interest, especially to the western farmer, is the part that the various roughages play in beef production. . . . One bushel of corn-and-cob meal fed with alfalfa hay as roughage produced 11.8 lbs. of flesh, while the same amount of corn-and-cob meal fed with sorghum hay as a roughage gave in return only 6.25 lbs. of flesh; thus, a difference of 5.5 lbs., or 88 per cent in favor of the alfalfa hay ration. . . .

"It is the opinion of the writer that the western feeds grown without irrigation have the chief food constituents in a slightly different proportion from those grown under more favorable conditions, though the nutritive ratio of the rations fed and the profit per steer have a direct relation to each other. For practical work the results would be little changed by this difference in composition."

Highland cattle, J. ROBERTS (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 88, pp. 227-241*).—This is reprinted from the annual report of the Bureau for 1904 (E. S. R., 17, p. 689).

Pigs and bacon (*Jour. Jamaica Agr. Soc., 10 (1906), No. 3, pp. 108-110*).—Data are summarized showing that bacon curing may be profitably carried on in Jamaica with local-grown pigs. The majority of the local feeding stuffs, it is pointed out, are very rich in carbohydrates and tend to produce fat rather than flesh. The pulp remaining after cotton-seed oil is expressed, peas, and cowpeas are spoken of as very satisfactory feeds for pigs raised for bacon.

Feeding of horses, E. LAVALARD (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 13-27*).—A summary and discussion of recent horse-feeding experiments in France, particularly those carried on upon a large scale.

Influence of foods containing sugar upon the digestibility of rations of horses, J. ALQUIER (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 1-12*).—On the basis of experimental evidence it is stated that sugar did not appreciably affect the digestibility of the nutrients of a ration even when as much as 5 or 6 kg.

per 1,000 kg. body weight was consumed. Sirup and molasses in smaller quantities, however, decreased digestibility, a fact which is explained by the laxative properties of the alkaline salts in beet molasses.

The toxicity and hygienic and therapeutic rôle of the mineral matter of molasses for horses, J. ALQUIER (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 69–85*).—From the experimental evidence presented the conclusion was drawn that molasses is harmless and a hygienic nutritive material when the amount consumed per day does not exceed 3 or 4 kg. per horse.

Hunter-horse production in Ireland, W. J. KENNEDY (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 87, pp. 187–225, pls. 8*).— This is reprinted from the annual report of the Bureau for 1904 (E. S. R., 17, p. 691).

The poultry industry of Petaluma, California, P. H. LAWLER (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 92, pp. 316–322, pls. 8*).—This is reprinted from the annual report of the Bureau for 1904 (E. S. R., 17, p. 692).

DAIRY FARMING—DAIRYING—AGROTECHNY.

The influence of changes in feeding upon milk production, J. L. HILLS (*Vermont Sta. Rpt. 1905, pp. 341–376*).—This is a compilation and discussion of the data obtained in the feeding trials reported in the tenth to the sixteenth annual reports of the station (1896–1903), inclusive, and relates to the effect upon production of changes in the total and digestible dry matter, digestible protein, digestible carbohydrates, and calories. Many deductions are made from the numerous tables which show in a condensed form, food consumption; production of milk, total solids, and fat with the food cost of each; and production proportioned to food consumption.

Among the author's generalizations are the following:

"(1) The testimony afforded by the results as between different rations and the same ration fed in different amounts is so nearly alike, speaking broadly, that one may safely group them together and argue on the basis of variations in dry matter or in nutrient consumption regardless of their origin.

"(2) When like quantities of the several nutrients were eaten, production was unaltered.

"(3) A 6 per cent increase or decrease in total dry matter eaten was accompanied by a corresponding 2 per cent change in yield; a 10 per cent increase or decrease, by a 5 per cent change in yield. . . .

"(4) A 7 per cent increase or decrease in digestible dry matter eaten was accompanied by a 3 per cent change in yield; a 12 per cent increase or decrease, by a 6 per cent change in yield; or, in other words, as food varied so did the yield, but to a less degree. . . .

"(5) As for digestible dry matter, so for digestible carbohydrates and for calories, word for word and, essentially, figure for figure.

"(6) A 3 per cent increase or decrease in digestible protein eaten had no effect on production; a 7 per cent increase or decrease was accompanied by a 2 to 3 per cent change in yield; and a 22 per cent increase or decrease by a 4 to 5 per cent change. . . .

"(7) A change in feeding of from more than to less than 15.5 lbs. of digestible nutrients or vice versa caused more decided changes in yield than did modifications in feeding on either side of that line, the average figures being 7 per cent and 4 per cent.

"(8) The nutritive ratio changes were evidenced in production fluctuations much as were those of digestible protein; when it narrowed, production generally increased, and vice versa.

"(9) The ultimate effect of a given food supply upon the milk flow is doubtless the more or less composite result of several coincidently active factors, including, primarily changes in the amounts of digestible nutrients taken as a whole; secondarily, changes in the amounts of digestible protein, and, probably, modifications in the proportions of digestible nutrients consumed in concentrates and in roughage.

"The writer's study of these data leads him to the conclusion that as a whole they do not support the doctrine which lays extreme stress on the paramountcy of protein; that they indicate that a ration with a nutritive ratio wider than 1:6, perhaps as wide as 1:7, or, indeed, in some cases one slightly wider, may prove economically as effective as the traditional 1:5.4; that a sufficiency of nutrients, affording enough available energy for bodily needs, if carrying a fair amount of digestible protein, not necessarily as much as 2.5 pounds, may prove economically as serviceable as does a richer ration."

Feeding trials with cows, J. L. Hills (*Vermont Sta. Rpt. 1905, pp. 377–404, 428–462*).—In the feeding experiments conducted during the year on the same general plan as in previous years (E. S. R., 17, p. 284) tests were made of India wheat meal, hominy feed, cotton-seed meal, and linseed meal, and further data were secured on the extent of experimental error in feeding trials. The experiments included 42 cows and covered a period of 25 weeks.

"*India wheat meal*, used in medium to small amounts, seemed a fair substitute, pound for pound, for wheat bran, and nearly so for a mixture of equal parts of cotton-seed and linseed meals, an outcome which its analysis would not have led one to expect and which has been confirmed by the concordant results of two seasons' trials.

"*Hominy feed* proved superior as a milk maker to a rather inferior grade of wheat bran, but did not appear to be the equal of cotton-seed and linseed meals, nor was it as economical a concentrate to use. This outcome has, likewise, the coincident testimony of two years' trials to back it.

"*Cotton-seed meal*, as compared with linseed meal, seemed to possess a small though measurable advantage as a milk and butter making by-product; and since it cost less and carried a greater plant-food content, it proved economically preferable."

When 6 to 8 animals are fed by the alternation system, it is believed that the experimental error may be held to be a negligible quantity.

A comparison of feeding trial methods, J. L. Hills (*Vermont Sta. Rpt. 1905, pp. 405–412*).—The results obtained during the year agreed with those previously reported, showing, in the opinion of the author, that the simple alternation system of conducting feeding trials is preferable to the combined method, but that the testimony of both is better than that of either alone.

Influence of sesame feeding on the yield of milk and the quality of milk, butter, and cheese, Moser, Peter, and Käppeli (*Jahresber. Molk. Schule Rütti-Zollikofen, 18 (1904–5), Beilage; abs. in Milchw. Zentbl., 2 (1906), No. 5, pp. 229–232*).—Sesame meal to the extent of 1 kg. per head daily produced a satisfactory increase in the yield of milk, but when increased to 1½ kg. was relatively less satisfactory.

The fat content of the milk showed no marked variations due to the feeding. The cheese was apparently unfavorably influenced by the larger quantities of sesame meal fed. The butter was regularly of good quality, although the opinions of the experts were not unanimous as regards the influence of this material on the quality of butter. In any case the influence on the butter was very small. With reference, therefore, to cheese making it is recommended that the quantity of sesame meal be limited to 1 kg. per head daily.

Influence on the fat content of milk of palm-nut cake as compared with rape-seed cake and peanut cake, T. von Szankowski (*Inaug. Diss., Univ. Halle, 1905; abs. in Milchw. Zentbl., 2 (1906), No. 5, p. 232*).—The author concludes that the palm-nut cake rich in fat exerts a favorable influence on the fat content of milk, the

cake poor in fat exerting more influence on the quantity of milk. The addition of oil acts unfavorably on both the yield and the fat content of the milk which, however, is not the case when the oil is present in the material in a natural state. Rape-seed cake in comparison with palm-nut cake increased the yield of milk but had no influence on the fat content. Peanut cake increased the yield of milk and fat only at the beginning of the feeding period.

Suggestions for construction of a modern dairy barn (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 90, pp. 6, figs. 2*).—It is the aim of this circular to present a plan for a dairy barn embodying the best ideas in scientific and sanitary construction consistent with practicability and cheapness.

Dairying at Park Royal, 1905, E. MATHEWS (*Jour. Roy. Agr. Soc. England, 66 (1905), pp. 93–111*).—Tests of the butter and milk production of a number of cows of different breeds exhibited at the show of the Royal Agricultural Society in 1905 and several butter-making experiments are reported. The experimental work was largely for the purpose of furnishing object lessons and consisted in making butter from milk obtained after short and long periods of secretion, comparing butter made from the milk of different breeds, churning at different temperatures, etc.

Record of the station herd for 1904–5, J. L. HILLS (*Vermont Sta. Rpt. 1905, pp. 422–427*).—Records of 52 cows for the year are reported. Some of the average results are as follows: Yield of milk 5,343 lbs., fat content 5.25 per cent, total solids 14.73 per cent, yield of butter 323.6 lbs., cost of food $58.31, and proceeds from sale of butter $96.93.

On the variations in the constituents of cows' milk during the course of lactation, F. PRACHFELD (*Inaug. Diss., Univ. Leipzig, 1905; abs. in Milchw. Zentbl., 2 (1906), No. 5, pp. 228, 229*).—The greatest variations in individual constituents occurred during the second and third months and at the close of the lactation period. Variations in fat, sugar, proteids, and ash decreased in the order mentioned. In general, the percentages of fat, proteids, and ash in the milk increased and the percentage of sugar decreased from the beginning to the second or third month of the lactation period, from which time on until the end of the period these relations were reversed.

Investigations on the relations of the properties of the blood (erythrocytes and hemoglobin) to the productive capacity of milch cows, E. SCHULTZ (*Fühling's Landw. Ztg., 55 (1906), No. 8, pp. 272–286*).—The investigations, which were made with 3 dairy herds, consisted in counting the red blood corpuscles and estimating the hemoglobin.

The red blood counts were found to be influenced by the age of the cows, stage of pregnancy, variations in altitude, and other causes. Averaging the data for the cows 4 to 6 years of age and of moderate productive capacity, a blood count of 6,320,000 erythrocytes per cubic millimeter was obtained for one herd, the production of which was 2,400 kg. of milk containing 3.76 per cent of fat; 6,640,000 for another herd producing 3,400 kg. of milk containing 3.08 per cent of fat; and 6,960,000 for a third herd producing 4,000 kg. of milk containing 4.01 per cent of fat, indicating a relation between the yield of milk and fat and the number of red blood cells.

The number of red blood cells showed a tendency to increase until the animals reached the age of 4 to 6 years, after which there was a decrease. There was also a decrease in the later stages of pregnancy. More dependence was placed upon the blood counts than upon the hemoglobin estimations, but in general the two determinations varied proportionately. With animals in advanced pregnancy and those kept at high altitudes the hemoglobin was relatively increased, while with young animals and those very productive the proportion of hemoglobin to red cells was reduced. A high content of hemoglobin and a high blood count are considered favorable to milk secretion, and it is suggested that these might be increased by breeding.

On the lecithin content of milk, W. KOCH (*Ztschr. Physiol. Chem., 47 (1906), No. 4-6, pp. 327-330*).—What has heretofore been reported as lecithin, the author considers a mixture of lecithin and cephalin. The two substances may be separated by precipitation of the cephalin from an alcoholic solution by means of an ammoniacal solution of lead acetate. Both lecithin and cephalin are considered present in milk in sufficient quantities for estimation. Failure to find lecithin in milk is believed to be due to the common error of treating lecithin as a fat and extracting with ether. Lecithin, however, does not behave the same as a fat and in separating milk it remains for the most part in the skim milk rather than being removed in the cream.

A comparison of the composition of the casein of human, cows', and goats' milk, E. ABDERHALDEN and A. SCHITTENHELM (*Ztschr. Physiol. Chem., 47 (1906), No. 4-6, pp. 458-465*).—From 200 gm. of water-free casein prepared from goats' milk, the authors obtained by hydrolysis, alanin 3 gm., leucin 14.8 gm., prolin 9.24 gm., phenylalanin 5.5 gm., glutaminic acid 22.5 gm., aspartic acid 2.2 gm., and tyrosin 9.9 gm. From 7 gm. of casein prepared from human milk 0.33 gm. of tyrosin and 0.28 gm. of glutaminic acid were obtained in the same manner. The albumin from human milk yielded 1.26 per cent of tyrosin and 0.98 per cent of glutaminic acid, the latter being considered much too low.

Preliminary communication on the glycocoll content of milk proteids, E. ABDERHALDEN and A. HUNTER (*Ztschr. Physiol. Chem., 47 (1906), No. 4-6, pp. 404-406*).—From a mixture of albumin and globulin prepared from cows' milk there were obtained by hydrolysis with hydrochloric acid, glycocoll, alanin, leucin, prolin, phenylalanin, glutaminic acid, and aspartic acid. Whether the glycocoll comes from the albumin or globulin or both is yet to be determined. The quantity is small, only 1.2 gm. of the ester being obtained from 100 gm. of the albumin or globulin.

A comparison of udder conformation and of milk production, J. L. HILLS (*Vermont Sta. Rpt. 1905, pp. 419-421*).—Five cows classed as having well-balanced udders produced on an average 5,725 lbs. of milk and 342 lbs. of butter yearly for an average of 3 years; 18 cows having fairly well-balanced udders, 5,377 lbs. of milk and 333 lbs. of butter yearly for 3.5 years; and 11 cows having poorly formed udders, 5,219 lbs. of milk and 324 lbs. of butter yearly for 3.6 years.

A comparison of the yield of the fore and hind quarters was made with 5 cows, the results showing a yield of 46 per cent for the fore quarters and 54 per cent for the hind quarters, the quality being practically identical. The results were the same whether the fore quarters or the hind quarters were milked first.

A trial of the Hegelund or Danish method of milking, J. L. HILLS (*Vermont Sta. Rpt. 1905, pp. 412-418*).—The Hegelund manipulation method was compared with extra-thorough stripping. The tests were made with 7 cows and covered 3 or 4 periods of 5 weeks' duration each.

When the Hegelund method was employed the first portion of the milking obtained in the ordinary manner was reduced in quantity and slightly in quality, but when taken with the residual milk obtained by manipulation the two portions together showed an increase in yield and a slight tendency toward better quality. With extra stripping the first portion showed likewise a reduction in quantity and quality, but when the strippings were added there was a gain in yield in but a single instance.

More food was consumed by the cows when the two special methods were employed, obviously introducing, according to the author, an element of doubt as to how much of the gain was due to manipulation and how much to increased food consumption.

The increased yield obtained by the Hegelund method was considered hardly more than sufficient to pay for the extra labor involved while the extra stripping was done at a loss.

"If, as is probably the fact, the persistency of the milking habit and the more per-

fect development of the udder are encouraged by either procedure, its adoption has considerable justification, particularly with heifers. This phase of the matter, however, is not included within the scope of the present inquiry. On the other hand, the additional load of dirt, dandruff, hair, dried manure, bacteria, etc., which fall into the milking pail because of the udder manipulation, is a distinct detriment, which, however, the use of some of the covered pails would go far to obviate."

The economic production and distribution of clean milk, J. Roby (*Jour. Amer. Med. Assoc., 46 (1906), No. 19, pp. 1430–1432*).—This discussion relates particularly to the milk supply of Rochester, New York.

Average monthly counts for 6 years showed the presence of about 100,000 bacteria per cubic centimeter in the milk supply of that city in winter and about 500,000 in summer. Notwithstanding the practical assurance of an increase of 3 cts. per quart in the price of milk, only one farmer was found who was willing to undertake the production of certified milk. In this instance the milk which was produced without expensive equipment showed on an average of 100 determinations the presence of only 3,853 bacteria per cubic centimeter.

In supplying milk to cities the author suggests the use of pails or cans holding about 15 qt. for milking, shipping, and, if desired, for delivering milk. After emptying, the cans are sent to a plant in the city where they are washed by machinery, covered with cheese cloth and a metal cover, and over both a stout canvas cover, and then sterilized by dry heat. The cans are then returned to the farm, where the canvas and metal covers are removed and the milk drawn directly through the cheese cloth into the can. The strainer is then removed and returned to the sterilizing plant with the canvas cover. The cans are at once covered and the milk is cooled by placing the cans immediately in ice water.

Investigations of the causes of the low Reichert-Meissl numbers of Holland butter, A. J. Swaving (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 9, pp. 505–520, dgms. 5*).—From September 15 to December 19, 5 groups of 4 cows each were fed different rations supplementing grass or hay and linseed cake and determinations were made of the Reichert-Meissl number of the butter made from the milk of each animal.

The content of volatile fatty acids was increased by fodder beets and by lucern silage. Grass silage exerted little or no influence as did also barley meal and sugar when fed as supplements to pasture and linseed cake. The Reichert-Meissl number was lowered by hay and linseed meal alone. While it is not yet clear in what manner the beets influence favorably the Reichert-Meissl number, the author considers that there is now better support for the previously expressed view that easily decomposed carbohydrates, such as sugar, favor the formation of volatile fatty acids only when fed along with materials already undergoing fermentation or easily fermented, such as fodder or sugar beets.

Bacteriological examinations of butter, A. Reitz (*Centbl. Bakt. [etc.], 2. Abt., 16 (1906), No. 7–9, pp. 193–212*).—This is a review of the literature on the occurrence of tubercle bacilli in butter, the bibliography given containing reference to the publications of 73 investigators. The author examined 100 samples of butter obtained in Stuttgart by means of inoculation experiments with animals. The results for 6 samples were inconclusive. In 8 or 8.5 per cent of the remaining samples, tubercle bacilli were found present.

Casein as an adulterant of butter, R. Racine (*Ztschr. Öffentl. Chem., 12 (1906), No 9, pp. 169, 170*).—A sample of adulterated butter showed the presence of 5.49 per cent of casein and 24.73 per cent of water.

The chemical composition of whey and curd during the manufacture of Emmenthal cheese, G. Koestler (*Milchw. Zentbl., 2 (1906), No. 5, pp. 193–224*).—According to the results of the author's investigations, the addition of rennet changes the chemical composition of the milk only to the extent of increasing the content of

soluble nitrogenous substances, the inclusion of which in the cheese may be regulated to a certain extent by manipulative methods.

At the time of cutting the curd, the whey shows, for the first few minutes, a decrease in the percentages of fat and proteids due probably to the effect of delayed coagulation, but later the fat content of the whey is increased. The acidity of the whey decreases during the process of manufacture due especially to the disappearance of carbon dioxid. The average of 38 determinations showed a decrease in acidity of 0.41 cc. of one-fourth normal potassium hydroxid per 100 cc. of whey. The total ash in whey decreases during the manufacturing process, the water soluble portion, however, showing an increase. The percentages of phosphoric acid and calcium are decreased.

The paracasein shows no changes in composition while in the kettle. The coagulating power of the whey due to the rennet remains constant until destroyed by the heating. A rapid increase in the acidity of the expressed whey is apparently due to an increase in the concentration of the whey and to lactic-acid fermentation.

Note on Dutch cheese, C. H. CRIBB (*Analyst, 31 (1906), No. 361, pp. 105-111*).—Analyses are reported of 25 samples of Edam, Gouda, and other types of cheese imported into England from Holland. Many of these samples showed less than 5 per cent of fat and were consequently considered as made wholly from skim milk. Failure to secure conviction in a trial for adulteration was due to the want of any standard for such cheese.

Carbonated milk, L. L. VAN SLYKE and A. W. BOSWORTH (*Abs. in Science, n. ser., 23 (1906), No. 592, p. 712*).—Fresh milk treated with carbon-dioxid gas under pressure of 60 to 70 lbs. kept from 10 days to 2 weeks at a temperature of 60 to 70° F. and made a very palatable, refreshing beverage. Further work is to be done along this line before the detailed results of the experiments are to be published.

Artificial milk, R. RACINE (*Ztschr. Öffentl. Chem., 12 (1906), No. 9, pp. 167, 168*).—An examination of a so-called artificial milk showed it to be a mixture of sirup and sesame oil emulsified with some proteid substance. This, diluted by the addition of 9 parts of water, is recommended for use in bakeries as a substitute for milk.

A new wine-cooling machine, F. T. BIOLETTI (*California Sta. Bul. 174, pp. 27, figs. 6*).—"The machine consists essentially of a copper tube 220 ft. long and 1¼ in. in diameter, through which the wine is pumped and which is inclosed in a canvas irrigating hose 4 in. in diameter, through which cold water runs in a direction opposite to that of the wine."

Preliminary tests with small models of this cooler are reported, as are also comparative tests of other cooling machines. It is thought possible that iron may be substituted for copper pipes, although this is not at present recommended, as tests have not been made on a practical scale. The leakage through the canvas hose permits the utilization of the cooling due to evaporation, which, under average working conditions in a dry climate, is estimated as equivalent to the use of water about 3° F. cooler in a machine where this evaporation could not take place.

Tests were made with water and must at different temperatures and with different ratios in the volumes of water and wine. One test of the new machine showed that 1,000 gal. of fermenting wine can be lowered from 95 to 78° in 1 hour by the use of 850 gal. of water at 71.5° Specifications are given for the construction of a cooler of this type suitable for the use of a cellar making not more than 300,000 gal. of dry wine during a vintage of 30 days with directions for using the cooler in order to secure the greatest efficiency, the latter including formulas and tables for calculating the number of degrees the must or fermenting wine must be cooled and the number of hours the cooler must be used.

The manufacture of Samshu (Chinese spirit) from Sorghum vulgare, E. H. WILSON (*Gard. Chron., 3. ser., 39 (1906), No. 1005, pp. 194, 195*).—This is a brief account of the methods employed in North China and Manchuria in the manufacture of this distilled liquor from sorghum seed.

VETERINARY MEDICINE.

Handbook of pathogenic micro-organisms, W. Kolle and A. Wassermann (*Handbuch der pathogenen Mikroorganismen. Jena: Gustav Fischer, 1906, Sup., pt. 1, pp. 384, pls. 7, figs. 27*).—This is the first supplemental volume to the large work published under the supervision of the editors and contains an account of trypanosomes, pyroplasmosis, tuberculosis of animals and man, bacterial hematoxins, amebic dysentery, leprosy, and typhoid fever. The latest literature relating to these topics is discussed in connection with bibliographies.

It appears from the review of the literature on tuberculosis that mammalian tubercle bacilli must be divided into 2 types, the human and bovine. It is possible to choose a dose so small that when bovine tubercle bacilli are used in inoculating experimental animals generalized tuberculosis results, while with a dose of the same size of human tubercle bacilli no infection takes place.

A treatise on the parasites and parasitic diseases of the domesticated animals, L. G. Neumann, trans. by G. Fleming (*London: Baillière, Tindall & Cox, 1905, 2. ed., pp. XVI + 697, figs. 365*).—The present edition has been revised and edited by J. MacQueen and contains as heretofore, but in a revised form, a detailed account of the parasites affecting domestic animals. These parasites are arranged according to the organs or parts affected as, for example, the skin, digestive apparatus, serous membranes, respiratory apparatus, circulatory apparatus, muscles, connective tissue, bones, nervous system, and genito-urinary organs. An elaborate bibliography of literature relating to this subject is appended to the volume (pp. 647–678).

Police sanitation of animals, A. Conte (*Police sanitaire des animaux. Paris: J. B. Baillière & Sons, 1906, 2. ed., pp. XII + 532*).—The government veterinary sanitation in France and her colonies is presented in great detail for the guidance of veterinarians who are concerned with this work.

In a preface to the volume E. Leclainche makes a number of suggestions regarding possible lines of improvement in existing laws. The volume as a whole is divided into three parts relating to veterinary sanitation of France, the colonies, and special information regarding the duties and functions of officials connected with the work.

An elaborate review of the development of the French veterinary laws is presented, together with a discussion of all general sanitary measures relating to the visitation of infected premises, declaration of infection, disinfection, indemnities, supervision of diseased animals, and the general practices of police sanitation.

Special chapters are also given on legislation relating to rabies, cattle plague, contagious pleuro-pneumonia, blackleg, tuberculosis, sheep pox, foot-and-mouth disease, glanders, dourine, swine erysipelas, hog cholera, etc.

Therapeutic technique, W. Schlampp (*Therapeutische Technik. Stuttgart: F. Enke, 1906, vol. 1, pp. VII+419, figs. 171*).—In this part of the author's work on the technique of general therapy for veterinarians attention is given to a discussion of therapeutic measures applicable to the skin. The material which naturally falls under this head is classified according to the nature of the remedies used.

Special chapters are devoted to application to the skin of various fluids, salves, pastes, soaps, varnishes, plasters, powders, and paints. The methods of removing the hair are also discussed and an account is presented of treatment of the skin by means of surgical operations, subcutaneous inoculation, irritation of the skin, the use of blisters, and methods adopted for the protection of animals against various parasitic skin infections. The nature and use of a large number of drugs are carefully considered.

Experimental studies on the permeability of the walls of the alimentary tract of newborn animals for bacteria and proteids, A. Uffenheimer (*Arch. Hyg., 55 (1906), No. 1–2, pp. 1–139, pl. 1*).—The author conducted a long series of

experiments in feeding new-born animals with virulent cultures of anthrax and tuberculosis, as well as with certain proteids.

In all cases great care was exercised not to injure the mucous membrane in any way so that the infection which followed could be attributed to the permeability of the intestinal walls for the bacteria in question. The experimental animals were guinea pigs and rabbits. By means of tubes and pipettes it was found possible to measure in a very accurate manner the amounts of bacterial cultures fed to the animals. During these experiments it was found that the anthrax bacillus leaves the alimentary tract very readily.

Within 6 hours after feeding the feces contained anthrax bacilli in large numbers, while after 17½ hours they were to be found only in isolated cases. The anthrax bacillus, however, did not lose its virulence in passing through the alimentary tract. It was found that young guinea pigs could be fed very large quantities of virulent anthrax bacilli without causing any infection. Even spore-bearing cultures failed to be pathogenic. When these experiments were carried out according to the requirements of von Behring the guinea pigs remained in perfect health.

In experiments with tubercle bacilli the results were quite different. Within a few days after feeding large quantities of tubercle bacilli, some bacilli were found in the glands of the omentum and liver. When only small quantities were fed, however, the tubercle bacilli could not be found in the glands. Apparently the bacilli passed through the walls of the alimentary tract very rapidly. In certain stages of the process, especially in the cecum and vermiform appendix, sections were made of this material and examined microscopically. Notes are also given on the permeability of the intestines for hemolytic serum, casein, albumen from hens' eggs, and various antitoxins.

Bacillus necrophorus and its economic importance, J. R. Mohler and G. B. Morse (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 91, pp. 76-116*).—This is reprinted from the annual report of the Bureau for 1904 (E. S. R., 17, p. 702).

Report of the chief inspector of stock, R. E. Weir (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 6, pp. 527-531*).—An account is given of the present government veterinary staff of Western Australia. Brief mention is also made of the prevalence of pleuro-pneumonia, tuberculosis, hog cholera, and Texas fever among animals as well as poisonous plants. The author discusses the present status of horse, cattle, and sheep raising and gives brief notes on the condition of pastures, abattoirs, and the registration of brands.

Books, memoirs, and articles on tuberculosis, Bouchez (*Rev. Tuberculose, 2. ser., 3 (1906), No. 1, pp. 98-120*).—A classified bibliography is presented of literature relating to tuberculosis in man and animals. The books and articles referred to are grouped under natural classes according to the organs affected by tuberculosis and into general groups—hygiene, pathology, therapeutics, experimental veterinary medicine, etc.

Cattle tuberculosis, H. Sessions (*New York: W. R. Jenkins, 1906, 2. ed., pp. VII+120*).—This edition has been practically rewritten and brought up to date by the addition of much new material, particularly with reference to the recent discoveries relating to tuberculosis in cattle. The subject-matter in the volume includes an introduction and chapters on human tuberculosis as related to bovine tuberculosis, cause of the disease, symptoms and diagnosis, tuberculin test, milk inspection, meat inspection, disposal of tuberculous carcasses, and insurance of cattle intended for slaughter.

Danger of infection with tuberculosis by different kinds of exposure, E. C. Schroeder and W. E. Cotton (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 83, pp. 44-65*).—This is reprinted from the annual report of the Bureau for 1904 (E. S. R., 17, p. 699).

Danger from ingestion of tubercle bacilli killed by heat, A. CALMETTE and M. BRETON (*Presse Méd.* [*Paris*], *1906, No. 15, p. 115*).—Young guinea pigs were fed a single dose of 1 to 2 cg. of tubercle bacilli of bovine origin freshly dried and mixed with potato or carrots.

In all cases the guinea pigs died of generalized tuberculosis after about 92 days. Further experiments were then made with bacilli which had been heated to a temperature of 100° C. for a period of 5 minutes. In guinea pigs which were fed such material in doses of 1 to 2 cg. infection took place promptly and death occurred within 37 to 48 days. Hypertrophy of the renal capsules was observed and other lesions resembling those which occur in animals inoculated with repeated large doses of tuberculin. It appears, therefore, that tubercle bacilli killed by heat are not inert bodies for susceptible animals.

The infectiousness of milk and meat from tuberculous animals, H. PERICAUD (*Prog. Vét., n. ser., 26* (*1906*), *No. 4, pp. 135–137*).—Attention is called to the fact that while bovine bacilli are doubtless very virulent for man they are seldom found in the meat of tuberculous animals. As a rule, therefore, such meat can be used without harm. Milk from tuberculous cows, however, must be considered as dangerous and should be sterilized in some manner before being used.

The frequency of tuberculosis in the dairies of Paris, H. MARTEL (*Rev. Soc. Sci. Hyg. Aliment., 2* (*1905*), *No. 6, pp. 559–563*).—Attention has already been called by the health authorities of Paris to the prevalence of tuberculosis among herds which furnish milk for the city. A tuberculin test carried out on 628 cows gave a reaction in 215, or 34.2 per cent, of the animals. On account of this large percentage it is urged that the measures prescribed by the health authorities of Paris be carried out strictly and that further precautions be taken to avoid the subsequent contamination of stables by the introduction of tuberculous animals or otherwise.

The lymphocyte and tubercle bacillus, J. BARTEL and W. NEUMANN (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig., 40* (*1906*), *No. 4, pp. 518–537*).—It has usually been assumed that the lymphatic organs and glands must exercise more or less influence upon tubercle bacillus for the reason that this bacillus is carried to so large an extent throughout the organism in the lymphatic system and affects in so large a per cent of cases the lymphatic glands.

Notwithstanding the apparent logical basis for such an assumption the demonstration of any direct influence of the leucocytes upon the tubercle bacillus has proved a difficult matter and in the case of most investigations only negative results have been obtained. In the author's experiments this matter was tested in vitro by placing material from the lymphatic glands in cultures of tubercle bacilli. Such material after varying lengths of time was used for further inoculation of experimental animals.

When the substance of mesenteric glands was used in such tests it was found that animals inoculated with the mixture did not become infected with tuberculosis and showed no infiltration at the point of inoculation or changes in the corresponding lymphatic glands. The substance of the spleen and the lymphatic glands appears, therefore, to exercise an important influence in combining the toxins of tubercle bacillus in essentially the same manner described by Brieger, Kitasato, and others. Tubercle bacilli kept in contact with such material for 22 days were not capable of producing any reaction at the point of inoculation.

Tuberculosis of the spleen in guinea pigs, C. ACHARD and P. EMILE-WEIL (*Arch. Méd. Expt. et Anat. Path.* [*Paris*], *18* (*1906*), *No. 1, pp. 71–84*).—A number of types of splenic lesions were observed in tuberculosis in the guinea pig. The ordinary splenic tuberculosis shows small granulations in the slightly congested parenchyma. In another type the tubercles fuse, causing a filtration of the organ. Hemorrhagic tuberculosis is also observed in some cases. In this type of the disease the spleen is much enlarged, weighing from 5 to 35 gm.

Experience with von Behring's method of protective vaccination of cattle against tuberculosis, SCHRICKER (*Wchnschr. Tierheilk. u. Viehzucht, 50 (1906), No. 7, pp. 121-128*).—Von Behring's method of vaccination against tuberculosis has been in practical use for 3 years and the results obtained, therefore, give a good foundation for judging its effectiveness.

The author vaccinated 76 animals by this method without any bad effects, and on evidence of live tubercle bacilli were found in any of the animals which were subsequently killed and examined. It is concluded, therefore, that a protective vaccination of calves under 4 months of age is capable of greatly increasing the resisting power toward tuberculosis and in some cases checks slightly the development of an infection already existing at the time of vaccination.

The prevention of tuberculosis in cattle, J. WILSON (*Dept. Agr. and Tech. Instr. Ireland Jour., 6 (1906), No. 2, pp. 300-304*).—Tuberculosis in cattle according to the author is chiefly spread by means of the air and food. Notes are given on these different methods of infection and on the prevalence of tuberculosis in England. It is estimated that from 5 to 10 per cent of the yearlings in England are infected, 10 to 20 per cent of 2-year olds, and 40 to 60 per cent of adult cows. Attention is called to the danger from mammary tuberculosis in cows and to the use of tuberculin and other methods in the detection and eradication of the disease.

Anthrax, D. LAN (*Rev. Facult. Nac. Agron. y Vet., 2. ser., 1 (1905), No. 6, pp. 173-176*).—Veterinarians in various parts of South America are frequently called upon to deal with outbreaks of anthrax. The author presents a brief account of the course of the disease and of the usual methods of vaccination to immunize animals against it.

Immunization of the guinea pig and rabbit against anthrax, F. MARINO (*Compt. Rend. Soc. Biol. [Paris], 60 (1906), No. 6, pp. 306-308*).—In the author's experiments it was found possible to vaccinate guinea pigs against anthrax by means of subcutaneous injections of the first vaccine. It was very difficult to produce immunity, however, by intraperitoneal injections.

Guinea pigs which withstood repeated subcutaneous injections of a mixture of anthrax and preventive serum from a rabbit or guinea pig frequently failed to resist the minimum mortal dose of the first vaccine. The normal serum of rabbits mixed with virulent anthrax and injected hypodermically into guinea pigs protects them against the disease.

The pathological anatomy of glanders, SCHÜTZ (*Ztschr. Veterinärk., 18 (1906), No. 2, pp. 49-62*).—This statement was originally prepared in 1882, for the guidance of army veterinarians in determining cases of glanders and for use in diagnosing the disease from pathological material sent to the veterinary school in Berlin. The article in its present form has been recently revised and brought up to date.

Observations on normal and rinderpest blood, F. S. H. BALDREY (*Jour. Trop. Vet. Sci., 1 (1906), No. 1, pp. 47-69*).—In a study of the normal blood it is found that the average number of red blood corpuscles was 7,298,484 per cu. mm. The number varied, however, from 5,600,000 to 9,100,000 and the number of leucocytes varied from 8,000 to 18,000.

In arriving at these averages a large number of counts were made. An examination was also made of the blood of animals which had been bled for the production of a protective rinderpest serum. In these animals it was found that the average number of red blood corpuscles was 3,713,000 per cu. mm. In animals actually suffering from rinderpest the number of leucocytes increases rapidly, rising to 32,000 by the fourth day. The relative proportion of the various elements in the blood is discussed for other diseases as compared with rinderpest.

Redwater in cattle, A. E. METTAM (*Dept. Agr. and Tech. Instr. Ireland Jour., 6 (1906), No. 2, pp. 248-260, pls. 3*).—This disease, under various names, occurs in North and South America, Africa, Australia, various parts of Asia, and Europe. The

blood parasite which causes the disease is described and notes are given on the symptoms of redwater or Texas fever. A summary account is also given of some of the experimental work done in this country on this disease.

Cattle tick investigation, A. MAYER (*Proc. La. Agr. Soc. and Stockbreed. Assoc., 1905, pp. 103-110*).—Attention is called to the great economic importance of the cattle tick.

This pest not only stunts the development of cattle so that they fail to reach their normal size, but also reduces the market price of cattle raised below the quarantine line. On account of the fact that there are large tick-free areas below the quarantine line cattle raised on such areas must be inoculated or gradually infested with ticks in early life, otherwise they are as susceptible to Texas fever as northern cattle. Considerable reliance is placed in the use of good dips for destroying ticks, but attention is called to the desirability of systematic work in exterminating the tick.

The etiology of pneumonia, RIES (*Berlin. Tierärztl. Wchnschr., 1906, No. 8, pp. 129, 130*).—Excellent opportunity was had for the study of this disease in horses. It appeared as an infectious disease without special localization in the lungs, and at the outbreak of the symptoms considerable catarrh was noted in the upper part of the respiratory passages, but this was much less pronounced than the catarrhal condition of the duodenum. The temperature rose on the second day to 40.5° C., but fell to normal again within 8 days.

The persistence of tetanus spores in the animal organism in a latent form, G. TAROZZI (*Centbl. Bakt. [etc.], 1. Abt., Orig., 40 (1906), Nos. 3, pp. 305-311; 4, pp. 451-458*).—Guinea pigs and rabbits were used in the experiments reported in this paper, being inoculated with virulent tetanus cultures which had been kept under aerobic conditions. Only 11 animals were used in the experiments for the purpose of determining whether and how long tetanus spores remain in a latent condition in inoculated animals.

It was found possible to demonstrate the spores in all cases in the liver, usually in the spleen, but, as a rule, not in the kidneys. The author considers that these experiments demonstrate that the tetanus spores pass into the general blood circulation from the point of inoculation and become located in various vital organs where they may persist in a virulent condition for a long period. When removed from such organs they are capable of producing very toxic cultures.

Infectious diarrhea of calves and liver disease of chickens, N. S. MAYO (*Estac. Cent. Agron. Cuba Circ. 22, pp. 4*).—Brief notes are given on the distribution of infectious diarrhea in calves together with notes on the rate of mortality and antiseptic treatment to be adopted in preventing the disease. For this purpose the author recommends creolin. A disease of fowls known as little liver is described. The disease is, however, not characterized by lesions in the liver, but by symptoms which closely resemble those of roup. In treating the disease the author recommends the use of potassium permanganate in water at the rate of 1 part to 60.

Diseases of the stomachs in ruminants, J. L. WEBB (*Natal Agr. Jour. and Min. Rec., 9 (1906), No. 1, pp. 1-7*).—Cattle are susceptible to various digestive troubles on account of their tendency to eat various indigestible or otherwise harmful substances. In this way hair balls are formed in the stomach and actual lesions may be produced as the result of eating bones or other materials with sharp points. An account is given of impaction of the omasum, gastritis, and parasitic irritation of the fourth stomach. In removing these parasitic worms the author recommends the use of a mixture of 2 oz. areca nut and 30 grains of arsenic made into 10 doses and given daily for a period of 6 days in bran.

Enzyms in cornstalks and their relation to cornstalk disease, T. M. PRICE (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 84, pp. 66-75*).—This is reprinted from the annual report of the Bureau for 1904 (E. S. R., 17, p. 702).

Observations on Bilharziosis among animals in India, R. E. MONTGOMERY (*Jour. Trop. Vet. Sci., 1 (1906), No. 1, pp. 15–46, pls. 2*).—The characters of the genus Bilharzia or Schistosomum are mentioned in some detail. The form which occurs commonly in cattle is *Schistosomum bovis*.

Particular attention is given in this article to bilharziosis in the horse. The author had opportunity to make a number of post-mortem examinations on affected horses in the plains and hill regions. In addition to the blood parasite which is described as new under the name *S. indicum*, various tapeworms, flukes, and roundworms were found as well as bots. Many of the cases under observation were complicated with surra. The abdominal cavity was found to be in a state of general congestion, as well as the liver and pancreas. The intestinal tract is also the seat of various pathological lesions. The blood parasite may best be obtained from the portal vein of the liver.

A brief bibliography relating to blood parasites in the horse and ass is appended to the article.

Prevention of sheep pox, D. D. GARCIA (*Gac. Med. Zool., 30 (1906), No. 4, pp. 51–54*).—On account of the wide distribution of this disease the importance of practical methods for its control is quite evident. The author calls attention to the use of a preventive and curative serum against sheep pox.

Dipping as a means of preventing ovine diseases, F. A. VERNEY (*Natal Agr. Jour. and Min. Rec., 9 (1906), No. 1, pp. 11, 12*).—Since *Amblyomma hebræum* is the species of tick which is concerned in carrying heartwater, it is recommended that sheep be dipped for the destruction of this tick in order to control the disease.

Sheep botfly, E. THIERRY (*Jour. Agr. Prat., n. ser., 10 (1905), No. 37, pp. 344, 345, fig. 1*).—The appearance and distribution of this insect are briefly outlined. No curative nor preventive remedies are known which are practical and effective. The palliative measures usually recommended are briefly discussed.

Some common parasites of sheep (*Dept. Agr. and Tech. Instr. Ireland Jour., 6 (1906), No. 2, pp. 295–299, pls. 2*).—A discussion is presented of scab mite, sheep ticks, nostril fly, sheep maggots, and biting lice, remedies being recommended for the control of each one of these troubles.

The life history of the twisted wireworms (Hæmonchus contortus) of sheep and other ruminants, B. H. RANSOM (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 93, pp. 7, figs. 2*).—The common stomach worm of sheep is described in its various stages and particular attention is given to a summary of its life history.

It appears that the sheathed embryos of this parasite on grass in infested pastures are capable of great resistance toward cold and desiccation. It is evident, therefore, that the parasite is not destroyed in pastures by the cold weather of winter. The life history of this worm is comparatively simple. The eggs in the feces of infested animals hatch and the young crawl up the stems of grass where they become covered with the sheath and are later taken into the stomach of sheep in grazing. Feeding experiments were carried out which showed that the worm is in a condition to develop in the stomach of sheep when eaten along with grass.

The best method of cleaning up infested pastures consists in burning the grass. It is quite uncertain how long a time must be allowed for the starvation of the embryos and vermifuges can not be depended upon to expel the worms entirely from infested sheep. Experiments are in progress to test the method of raising lambs free from infection.

Swine plague, SCHMIDT (*Berlin. Tierärztl. Wchnschr., 1905, No. 51, pp. 865–869*).—This is a controversial article in which attention is called to the more or less incompatible claims made by various investigators and to the recent discoveries made by the Bureau of Animal Industry in regard to a form of hog cholera caused by a filterable virus. An editorial note is appended to the article in which it is stated that

the subject of swine diseases was not discussed so thoroughly at the recent international veterinary congress as the diseases of other animals.

The immunization against swine plague by means of bacterial extracts, J. CITRON (*Ztschr. Hyg. u. Infectionskrank., 52 (1906), No. 2, pp. 238–262*).—During a long series of experiments it was clearly shown that it is possible by means of a serum obtained from actively immunized rabbits to protect other rabbits, guinea pigs, and white mice against doses of bacteria many times the fatal size. The serum of normal rabbits in smaller quantities did not increase the resisting power of animals into which it was inoculated. The author believes, therefore, that the existence of specific complements in the blood is shown beyond question.

Through what agency is the Trypanosoma evansi carried over from one surra season to another? A. LINGARD (*Jour. Trop. Vet. Sci., 1 (1906), No. 1, pp. 92–112*).—Surra is usually fatal in horses, asses, mules, camels, goats, sheep, rats, dogs, and buffaloes. In cattle, however, both in the plains and hill breed, the disease when uncomplicated frequently terminates in recovery.

Cattle may carry the blood parasite for long periods, at least exceeding a year, and are, therefore, the only domestic animals found by the author to be capable of resisting spontaneous inoculation with trypanosomiasis. It is important, therefore, to determine whether cattle affected with this chronic form of the disease are agents in its transmission. As a result of the author's investigations it was found that the blood of cattle affected with the chronic form of the disease, when inoculated into susceptible horses, causes fatal cases of trypanosomiasis, and from such cases the rapid dissemination of the disease may occur.

Camels may also carry the disease for from 9 to 12 months and their blood is likewise pathogenic for horses. It is also found that dogs and cats are susceptible to the disease carried by camels. It is probable, although not definitely demonstrated, that various other wild carnivorous animals may be the agents in carrying the disease. The most rational system of controlling the disease, in the author's opinion, consists in the destruction of all affected horses in which the disease occurs in a virulent form.

Tibarsa surra, H. T. PEASE (*Jour. Trop. Vet. Sci., 1 (1906), No. 1, pp. 70–91*).—Camels have long been known to be susceptible to surra and considerable attention has been given to a study of this disease, with particular reference to its relation to other similar blood diseases. As a result of the author's investigations it is concluded that the form of surra which occurs in camels is due to *Trypanosoma evansi*, the same species which occurs in horses. The disease is often found affecting camels, horses, and mules in the same locality and is apparently due to the same cause.

A specific serum for Trypanosoma brucei and its effect upon T. gambiense, F. K. KLEINE and B. MÖLLERS (*Ztschr. Hyg. u. Infectionskrank., 52 (1906), No. 2, pp. 229–237*).—A serum was obtained from asses infected with *T. brucei*, which protected mice against fatal doses of this organism. It was observed, however, that the serum did not protect the animal from which it was obtained. Actively immunized trypanosomes inoculated into normal animals soon lost their immunizing property, so that a specific serum was found to be more active in the case of such animals. The serum showed considerable difference in its effect upon *T. brucei* and *T. gambiense*.

The action of brilliant green on the trypanosomes of nagana, H. WENDELSTADT and T. FELLMER (*Ztschr. Hyg. u. Infectionskrank., 52 (1906), No. 2, pp. 263–281, pl. 1*).—Brilliant green was administered subcutaneously in doses of 1 cc. in solution in the proportion of 1:200.

It was found that when experimental animals were thus treated the trypanosomes in the blood were soon affected to such an extent that they would not cause infection when inoculated into another animal. In the course of time brilliant green causes the entire disappearance of trypanosomes in the blood of rats, monkeys, and other experimental animals. The addition of small quantities of arsenic increases

this action. In the process of disintegration of trypanosomes in the blood under the influence of brilliant green a number of peculiar developmental forms were observed.

Piroplasmoses, L. PANISSET (*Rev. Gén. Méd. Vét., 7 (1906), No. 75, pp. 113–127, fig. 1*).—The distribution of these diseases throughout the world is briefly outlined, and descriptive notes are given on piroplasmoses in sheep, horses, and dogs, with an account of the symptoms and lesions in each case, etiology of the various forms of the disease, the agency of ticks in transmitting the disease, and immunization by means of vaccine and serum.

Piroplasmosis complicated with horse sickness, THEILER (*Rev. Gén. Méd. Vét., 7 (1906), No. 76, pp. 178–181*).—Brief notes are given on the occurrence of piroplasmosis among horses after inoculation with the virus of horse sickness. The development of piroplasmosis was due to the use of infected blood.

The treatment of nail pricks of the horse's foot, E. L. MOORE (*South Dakota Sta. Bul. 95, pp. 17–22*).—Attention is called to the fact that even slight injuries to the foot may develop serious complications on account of the fact that the foot is constantly in contact with the dirt which may carry bacteria.

In treating cases of nail pricks, followed by the formation of pus, the author obtained excellent results by cleansing the hoof with soap and water, paring away the horn of the hoof from around the affected part, then washing the part in a solution of corrosive sublimate, after which a piece of absorbent cotton is placed on the hoof and the whole firmly bandaged and covered with a thick coating of tar. A little cotton is allowed to extend above the tar bandage, and the corrosive sublimate solution may be applied daily without removing the bandage. This bandage should be left in place for from 7 to 10 days without being disturbed. Detailed clinical notes are given on a number of cases.

Poisoning of horses by Ornithogalum thyrsoides, D. HUTCHEON (*Agr. Jour. Cape Good Hope, 28 (1906), No. 2, pp. 165–172, pl. 1*).—A report was previously made on the death of horses from eating this plant and experiments were made in feeding dried plants which proved to be exceedingly poisonous. Further experiments were carried out in feeding the fresh green plant, and these experiments furnished the basis for the present article. It was found that two pounds of the fresh plant were sufficient to cause death in ponies within 2 days. The symptoms of poisoning are briefly discussed and notes are given on the distribution of the plant.

Examination of the Western Australian poison plants, E. A. MANN (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 6, pp. 550–561, pls. 5*).—Chemical analyses were made of various poisonous plants, including *Gastrolobium calycinum* and other species of this genus, as well as species of Oxylobium, particular attention being given to the first-named species. An alkaloid known as cygnin was isolated and was used in physiological tests with guinea pigs. It was found that this alkaloid was fatal for ordinary guinea pigs in hypodermic doses of $\frac{1}{10}$ to $\frac{1}{20}$ of a grain.

The rabies corpuscles of Negri, J. SCHIFFMANN (*Ztschr. Hyg. u. Infectionskrank., 52 (1906), No. 2, pp. 199–228*).—As the result of an extensive study of these bodies the author found that at times they may not be present in the medulla or spinal cord. They are subject to considerable variation with regard to their structure, distribution, and occurrence in the hippocampus and cerebellum, but this variation is independent of the incubation period and number of inoculations which have been made with the virus. After repeated passages of the virus Negri's corpuscles may be entirely absent in the hippocampus and cerebellum.

The tapeworms of American chickens and turkeys, B. H. RANSOM (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 85, pp. 268–285, figs. 31*).—This is reprinted from the annual report of the Bureau for 1904 (E. S. R., 17, p. 704).

RURAL ENGINEERING.

Irrigation investigations (*Kansas Sta. Rpt. 1905, pp. 26-41*).—This gives the results of investigations of irrigation at Fort Hays and Garden City, Kansas, carried on in cooperation between the Kansas Station and this Office. An account of this work was also given in Bulletin 158 of this Office (E. S. R., 17, p. 705).

Report of the reconnaissance of the Vaal River, F. A. HURLEY (*Pretoria: Transvaal Irrig. and Water Supply Dept., 1905, pp. XV+76, pls. 26*).—This report contains "preliminary descriptions and approximate estimates of the most favorable irrigation schemes practicable" from Vaal River in South Africa, a stream with an annual discharge of about 2,500,000 acre-ft., of which about 65 per cent passes during March floods.

Six projects are included, the two most urgently recommended irrigating 11,800 acres in the Transvaal and 27,800 acres in Orange River Colony. The third and fourth projects would irrigate 60,000 and 20,000 acres, respectively, while the fifth, which would involve an expenditure of about $25,000,000, would irrigate 400,000 acres, an undertaking not to be considered at present. The sixth project involves only Cape Colony land and is an expensive storage project not fully worked out as yet. The estimated costs per acre runs as follows: $77, $63, $76, $96, $50-60, and $112.

The annual water rate assumed is $5 to $7.50 per acre, and the increment in value of land $50 to $75 per acre. Maintenance charges are assumed to be about one-fifth of the water rentals, and the net return on the entire investment is estimated as about 6 per cent, except in the sixth project, where it is but 3.3 per cent. If the total increase in value of the land is deducted from the cost of the projects the estimated earnings run 126, 24, 14, 31, and 6 per cent, the fifth project not being included.

The duty of water is estimated on the basis of the severest possible system of cropping with a 3-year rotation of wheat, tobacco, vetches and rye, potatoes, beets and roots, vetches and rye, tobacco, and potatoes. It is further supposed that each irrigation will be 4 in. in depth and that in all 17 irrigations will be required in 3 years, the time of sowing and rainfall being considered. Allowing for 60 per cent loss, 1,000,000 cu. ft. of water must be stored annually for each 5 acres, or about 150 acres per cubic foot per second for a 9-months' season, allowing 20 per cent for roads and waste land. In order to meet the possible requirement of a 4-in. irrigation of the whole area in one month, the estimates for canals are on the basis of 100 acres per cubic foot per second. These estimates are reasonable when compared with the usual duty of 100 acres per cubic foot per second in Egypt, 100 to 300 in India, 120 and 150 under two California canals, and 150 in Spain and Italy.

In reviewing the subject of water rates the author cites as examples tracts in Cape Colony where land and water rent for $20 to $22 per acre, while in India the rate is about one-tenth and in Egypt one-seventh of the gross value of crops produced. Regarding the Reclamation-Act projects in the United States he says: "It would seem that the rates have been pitched very low to attract settlers." The rate assumed on the Vaal of $5 per acre is believed to be less than one-tenth the value of a crop of wheat and corn, the least valuable crops likely to be grown. The total cost to the renter, assuming 6 per cent interest on the value of the land, is considered reasonable, since it falls under $12.50 per acre annually.

A note by the director of irrigation, W. L. Strange, is included, in which it is stated that $15,000,000 in produce was imported into the Transvaal in 1904, showing a good market for irrigated products. He points out that the financial failure of irrigation works has usually been due to slow settlement, and that hence large works should be built by the State, which can afford to wait for returns in the form of general prosperity, and that the development of irrigation works should not outrun the normal settlement of the country.

Agriculture in the valley of the Ahr, H. DUPAYS and L. LEBRUN (*Jour. Agr. Prat., n. ser., 11 (1906), No. 8, pp. 241-248, figs. 5*).—This article describes briefly irrigation practice in the valley of the Ahr. The irrigation works are simple. The ditches are usually made with rectangular cross section in order that they may take up no more room than is necessary. Water is carried in rectangular flumes made of galvanized iron supported on I-beams. The water is used on meadows, the charges for water being 20 marks per hectare per year.

Pumping machinery at Mildura (*Impl. and Mach. Rev., 31 (1906), No. 372, p. 1406*).—At Mildura, Victoria, water is pumped for 8,000 acres of land. The water is raised at three separate lifts, 20, 25, and 25 ft. Water is pumped at the rate of 26,000 gal. per minute. As a rule there are five irrigations during the year, each lasting 28 days, and the pumps are run at a cost of $300 per day, or about $42,000 per year. The fuel is wood. The costs are met by a water tax which varies from 30 to 40 shillings per acre for the land covered. The land receives an average depth of about 22 in. per annum.

A Hawaiian pumping plant for irrigation (*Engin. Rec., 53 (1906), No. 10, p. 350*).—A description of a plant utilizing a small mountain stream by means of impulse wheels and an electric power plant. A method for regulating the speed of the dynamo, motor, and pump has been adopted so that the efficiency is not impaired when the supply in the hills is short. Larger impulse wheels are then used, giving a slower speed to the generator. With an automatic device to keep the field constant the voltage and cycles are diminished in proportion, the motor then falling off in speed without decreased efficiency.

Canals and ditches, M. RINGELMANN (*Jour. Agr. Prat., n. ser., 11 (1906), No. 7, pp. 210-212, figs. 8*).—This article summarizes foreign and American measurements of percolation of water from ditches, and discusses methods of prevention of losses in canals used for carrying water. It describes methods of preventing seepage losses, including concrete lining, masonry lining of ditches with rectangular cross sections, and the use of flumes.

The Belle Fourche dam, Belle Fourche project, South Dakota, R. F. WALTER (*Engin. Rec., 53 (1906), No. 9, pp. 307-310, figs. 7*).—This dam is one of the largest earth dams in the United States, being over a mile in length and containing 1,600,000 cu. yds. The details of the wasteway, conduits, and gates are described in detail. An unusual feature is the proposed concrete-block facing laid over gravel in lieu of riprap.

The Belle Fourche irrigation works, South Dakota, W. W. PATCH (*Engin. News, 55 (1906), No. 8, pp. 210-212, figs. 5*).—A brief account of the project, with a description of the more important structures used.

The drainage of earth roads (*Engin. Rec., 53 (1906), No. 18, pp. 564-566*).—This is an abstract of a bulletin on this subject by Prof. Ira O. Baker, published by the University of Illinois.

It is recommended that tile drains be laid at the side of the road at a depth of 3 or 4 ft., such a drain on one side of an ordinary country road being held to be sufficient. The drain might be more effective in the middle of the road, but the expense of putting it in would be so much greater that a drain at the side of the road is preferred. There is no limit to the steepness of the grades on which tile drains may be used, but the grade should not be less than 2 in. per 100 ft. It is important that the tile drains should have a free outlet. The cost of putting in 5-in. tile drains is given as $200 to $250 per mile.

Side ditches are necessary whether the tile is used or not. These should be broad rather than deep, with easy slope toward the road in order that vehicles may not be harmed if they get into these ditches. Water should not be carried long distances in these side ditches, but outlets should be provided at short intervals. Roads should be crowned sufficiently to provide for rapid surface drainage into the side ditches.

Where the roads are in excavation catch waters should be provided to keep drainage water off of the road. For maintaining the surface of roads in good condition, harrowing or dragging with a railroad rail, heavy timber, or split log is recommended.

The mixing of concrete, E. McCullough (*Sci. Amer. Sup., 61 (1906), No. 1580, pp. 25316–25318*).—The author states briefly the advantages of concrete over stone, calls attention to the necessity of thorough mixing, and compares hand mixing with various types of mechanical mixers. He favors the cube mixer.

Report of the commission on alcohol appointed by the minister of finance (*Jour. Agr. Prat., n. ser., 11 (1906), No. 15, pp. 454, 455*).—This commission, appointed to inquire into proper legislation for controlling the manufacture and sale of alcohol, recommended in regard to denaturized alcohol that: (1) In order to avoid adulteration the dealers should be required to label their goods in a conspicuous manner "denaturized alcohol, guaranteed 90 degrees;" (2) denaturized alcohol should have the benefits of reduced rates of transportation granted to refined petroleum; (3) that the vessels for denaturized alcohol which are returned empty to the shipper should be carried free on the state railroads, or pay the rates charged for merchandise of the fourth or fifth class on private lines; (4) so far as possible the formalities observed in the distribution, storage, and sale of denaturized alcohol should be simplified.

MISCELLANEOUS.

Sixteenth Annual Report of Arizona Station, 1905 (*Arizona Sta. Rpt. 1905, pp. 26*).—This contains the organization list of the station, a review of the work of the station during the year by the director, a financial statement for the fiscal year ended June 30, 1905, and departmental reports, some of which are noted elsewhere.

Annual Report of Idaho Station, 1905 (*Idaho Sta. Rpt. 1905, pp. 48*).—This includes a financial statement for the fiscal year ended June 30, 1905, a report of the director on the work and publications of the station during the year, and experimental work and meteorological observations abstracted elsewhere in this issue.

Eighteenth Annual Report of Indiana Station, 1905 (*Indiana Sta. Rpt. 1905, pp. 46*).—This consists of the report of the director and heads of departments, a list of periodicals received by the station library, a subject list of the bulletins of the station to date, and a financial statement for the fiscal year ended June 30, 1905. The report of the director contains a list of the cooperative experiments in progress July 1, 1905, and the report of the chemist an analysis of a sample of cattle food which was found to contain 96.73 per cent of sodium chlorid. The report of the horticulturist is noted elsewhere.

Eighteenth Annual Report of Kansas Station, 1905 (*Kansas Sta. Rpt. 1905, pp. 55*).—This contains a financial statement for the fiscal year ended June 30, 1905, a report of the council including abstracts of bulletins issued during the year, brief summaries of the work of the different departments not reported upon in bulletins, a report on the work of Fort Hays Branch Station, a statement concerning cooperative experiments with this Department, a subject list of station publications issued to date, and an index to the report and the bulletins issued during the year.

Fourteenth Annual Report of Kentucky Station, 1901 (*Kentucky Sta. Rpt. 1901, pp. XV + 308*).—This report, only recently issued, contains a financial statement for the fiscal year ended June 30, 1901, brief reports of the director and heads of departments for that year, miscellaneous chemical analyses and meteorological observations noted elsewhere, and reprints of Bulletins 91–97 of the station on the following subjects: Enemies of cucumbers and related plants (E. S. R., 13, p. 368); experiments with potato scab (E. S. R., 13, p. 360); the food of the toad (E. S. R., 13, p. 325); grapes (E. S. R., 13, p. 355); diseases of nursery stock (E. S. R., 13, p. 571); rabbits and their injuries to young trees (E. S. R., 13, p. 531); wheat (E. S. R., 13, p. 737); commercial fertilizers (E. S. R., 13, p. 730); the Hessian fly (E. S. R.,

13, p. 968); dangerous mosquitoes in Kentucky (E. S. R., 13, p. 971); poisonous and edible mushrooms (E. S. R., 13, p. 920), and commercial fertilizers (E. S. R., 13, p. 935).

Fifteenth Annual Report of Kentucky Station, 1902 (*Kentucky Sta. Rpt. 1902, pp. XVI+349*).—This contains a financial statement for the fiscal year ended June 30, 1902, a report of the director on the work of the station, including the fertilizer and food-control work, miscellaneous chemical analyses and meteorological observations noted elsewhere, and reprints of Bulletins 98–104 of the station on the following subjects: Kentucky forage plants (E. S. R., 14, p. 241); experiments with oats (E. S. R., 14, p. 242); inspection and analyses of foods (E. S. R., 14, p. 277); a comparison of feeds for pigs (E. S. R., 14, p. 283); analyses of commercial fertilizers (E. S. R., 14, p. 558); Hessian fly experiments (E. S. R., 14, p. 987), and analyses of commercial fertilizers (E. S. R., 14, p. 953).

Eighteenth Annual Report of Louisiana Stations, 1905 (*Louisiana Stas. Rpt. 1905, pp. 32*).—This contains reports of the Sugar Station at Audubon Park, New Orleans, the State Station at Baton Rouge, and the North Louisiana Station at Calhoun; statements concerning the work of the State geological survey and the United States Geological Survey in the State, and a financial statement for the fiscal year ended June 30, 1905.

Finances, meteorology, index (*Maine Sta. Bul. 124, pp. 227–268+VII*).—This bulletin consists of meteorological observations noted elsewhere, a financial statement for the fiscal year ended June 30, 1905, an index to the station reports for 1901–1905 and to bulletins 112–124, which collectively make up the twenty-first annual report of the station, and announcements and notes concerning the station.

Eighteenth Annual Report of Michigan Station, 1905 (*Michigan Sta. Rpt. 1905, pp. 81–539*).—This contains a financial statement for the fiscal year ended June 30, 1905; reports of the director and heads of departments, summarizing briefly some of the results of experiment station work during the year; meteorological observations noted elsewhere; and reprints of Bulletins 217–231 and Special Bulletins 24–33 of the station, which have already been noted.

Report of work at McNeill Branch Station, 1904, E. B. FERRIS (*Mississippi Sta. Bul. 87, pp. 16*).—Brief notes are given on weather conditions during the year and experiments with fruits, vegetables, and field crops are reported. The experimental work is abstracted elsewhere in this issue.

Eighteenth Annual Report of Vermont Station, 1905 (*Vermont Sta. Rpt. 1905, pp. 245–466*).—This includes the organization list of the station, a brief announcement concerning the station, a financial statement for the fiscal year ended June 30, 1905, a report of the director, abstracts of Bulletins 109–116 of the station issued during the year, and numerous articles abstracted elsewhere in this issue.

Abstract of Eighteenth Annual Report, 1905 (*Vermont Sta. Bul. 119, pp. 19–64, fig. 1*).—This is a résumé of the annual report of the station noted above.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, vol. 7, Nos. 11, pp. 95–102; 12, pp. 103–110*).—These numbers contain the usual statistics on the condition of crops in the United States and foreign countries and special articles on imported tobacco, exports of butter, imports of agricultural products into the United Kingdom, damage to the Cuban tobacco crop, the British market for Indian corn, and other topics.

Experiment Station Work, XXXIV (*U. S. Dept. Agr., Farmers' Bul. 251, pp. 32, fig. 1*).—This number contains articles on the following subjects: American sugar-beet seed, stimulants for seeds, profits from spraying potatoes, winter-injured fruit trees, durum wheat, fertility of eggs, indoor *v.* outdoor feeding of steers, roughage for steers, cheap dairy rations, and cotton-seed meal for hogs.

NOTES.

Colorado College.—A short course in horticulture was provided for by the State board of agriculture at its last meeting, to be held at Delta some time during the coming winter. This was done with the understanding that there would be at least fifty students regularly enrolled. One hundred have already signed the enrollment.

Delaware Station.—At a recent meeting of the board of trustees A. T. Neale was relieved of duty as director of the station, and was appointed in charge of the departments of agronomy and animal husbandry. This change went into effect July 1. A successor to Dr. Neale as director has not yet been elected.

Georgia Station.—Under the provisions of the Adams Act, the station proposes to inaugurate two new departments, i. e., departments of plant breeding and pathology (R. J. H. De Loach, of Athens, Ga., in charge), and of bacteriology. J. F. Monroe, of Guelph, Ontario, and P. N. Flint, of Cement City, Mich., have been made assistants in the departments of horticulture and animal industry, respectively.

Idaho University and Station.—Work is in progress on the new agricultural building, which is to be a brick structure 65 by 127 ft. in size and 3 stories high. The building will afford accommodations for the agricultural work of the university as well as the experiment station.

The people of Caldwell have donated 320 acres of land for an "auxiliary station," where experiments may be carried on under irrigation and dry-land farming.

Illinois University and Station.—The agricultural building at the university is undergoing an overhauling to secure space made necessary by the unexpected increase in students and by the demands of the station. The dairy department is now occupying the rooms made vacant by the removal of the household science department to the woman's building; the stock-judging room is being floored to provide an additional class room, and laboratories throughout the building are to be doubled in size.

A farm mechanics building, 100 ft. square and 2 stories high, is being erected. This will enable the entire southeast wing, which has been used for the farm mechanics work, to be fitted up for soil physics and crop work. When the agricultural building was erected there were but 19 students in agriculture and 7 instructors and investigators. Now the students have increased to 430, and there are 44 employees in the college and station—all within the space of 6 years.

Louisiana University and Stations.—E. Rosenthal, from the agricultural college, Madison, Wis., has been elected dairyman of the station at Calhoun. J. G. Lee, jr., of the class of 1906 of the university, has been placed in charge of feeding experiments at the station at Calhoun. H. R. Fulton has been elected to the position of plant pathologist at the station at Baton Rouge. Mr. Fulton is a graduate of the University of Mississippi, took his master's degree at Columbia, Mo., and has been taking work at Harvard the past year. H. J. Milk, of Watertown, N. J., has been elected bacteriologist of the stations, and will devote his time to the investigation of animal diseases.

The legislature passed a bill giving $50,000 for a new chemical laboratory for the university. The foundation is now being laid for a building to be devoted to experimental engineering.

Missouri Station.—Leonard Haseman, recently connected with the Florida University and Station, has been appointed assistant in entomology. C. R. Crosby, assistant in entomology, has gone to the New York Cornell Station.

Cornell University and Station.—T. L. Lyon, of the Nebraska University and Station, has been appointed agronomist in the station. W. A. Stocking, jr., for several years past connected with the Connecticut College and Storrs Station, has been elected assistant professor of dairy bacteriology in the college of agriculture.

The next winter dairy course at the university will open Thursday, December 6, and close Wednesday, February 27, 1907. This is about four weeks earlier than the course has been started heretofore. The change is made possible by the new dairy building and increased number of instructors for next year, which will permit both the long and short courses to be in progress at the same time. Nine-tenths of last year's class expressed themselves in favor of the earlier date.

Oklahoma College and Station.—At a recent meeting of the board of regents, A. T. Kruse, of Geary, Okla., appointed to succeed H. G. Beard, resigned, was elected treasurer of the board. E. H. Riley was relieved of station work to give all of his time to the school of agriculture and domestic economy. Roy C. Potts, a graduate of the Michigan Agricultural College, was appointed assistant in dairying in the college and station, vice C. H. Tourgee.

Texas College and Station.—John A. Craig resigned his position as dean and director July 1, and will give his attention to stock raising.

Vermont University and Station.—N. J. Giddings, a graduate in the agricultural department of the class of 1906, has been elected assistant botanist in the station to succeed W. J. Morse, who, as previously noted, resigned to accept a position at the Maine Station. H. A. Edson, a graduate of the chemical department of the class of 1906, assumes some of Professor Morse's college duties, and incidentally does some work for the station along botanical lines.

Virginia Station.—A large experimental orchard of dwarf apple trees on Doucin stocks was planted the past spring to determine the value of dwarf trees for commercial work. This orchard contains representatives of all the leading commercial varieties. This is the first orchard of its kind in the South, and the outcome is awaited with interest. The value of dwarf trees in relation to the horticultural operations of pruning, spraying, and harvesting is obvious, but questions of yield and hardiness in this climate are unsettled.

Extensive cooperative investigations relative to tobacco have been arranged for between the Bureau of Soils of this Department and the station. B. G. Anderson and W. L. Owen, graduates of the college of agriculture, have been appointed as the station's representatives to take charge of the cooperative work in the dark-tobacco belt at West Appomattox and in the light-tobacco belt at Chatham.

U. S. Department of Agriculture.—Dr. C. F. Langworthy, who has long been associated with the nutrition investigations assigned to this Office, formerly directed by Prof. W. O. Atwater, has been given general charge of this work, under the supervision of the director of the Office.

Dr. Ulysses G. Houck has been selected to have immediate charge of the new meat inspection work in the Bureau of Animal Industry. Dr. Houck was formerly a traveling inspector in the field. He will hereafter be located in Washington.

Dr. R. P. Steddom, chief of the Inspection Division of the Bureau of Animal Industry, will have immediate charge of the work on tick eradication provided for in the new appropriation act, and of the field work on the eradication of scabies in sheep and cattle.

Dr. Charles A. Browne, jr., recently chemist at the Louisiana Sugar Station at New Orleans, has been appointed chief of the sugar laboratory in the Bureau of Chemistry, this Department. He entered upon his duties early in July.

A. J. Pieters, in charge of the seed and plant introduction in the Bureau of Plant Industry of this Department, has announced his intention of resigning from the Department service in the early fall to engage in private business.

Cooperative Experiment Association of the Great Plains Area.—The first annual meeting of the Cooperative Experiment Association of the Great Plains Area was held at Lincoln, Nebraska, June 21–22, 1906. This association consists of those members of experiment stations who are interested in field-crop work in the States of North Dakota, South Dakota, Nebraska, Oklahoma, and the north of Texas, together with representatives of the Bureau of Plant Industry of this Department who are interested in experiments in crop rotation and tillage in that region. The association was organized at the time of the annual convention of the Association of American Agricultural Colleges and Experiment Stations at Washington in 1905, with B. T. Galloway as president and E. C. Chilcott as secretary.

This first annual meeting at Lincoln was a very successful one, both in point of attendance and the interest and enthusiasm manifested. Eleven members of the Department of Agriculture were present and about fifteen experiment workers. The following were among the papers read: Effect of Crop Rotation on Soil Fertility, J. H. Shepperd, North Dakota; Comparative Value of Corn and Summer Fallow in Alternation of Wheat, John S. Cole, South Dakota; Drought Resistance of Sorghum Crops, A. H. Leidigh, Bureau of Plant Industry, Amarillo, Texas; Seed Selection Essential in Crop Production under Semiarid Conditions, W. H. Olin, Colorado; Proposed Physical Investigations in connection with the Cooperative Cultivation Experiments, L. J. Briggs, Bureau of Plant Industry; Crop Production in Western Kansas, O. H. Elling, Fort Hays, Kansas. These papers and many other subjects of similar nature were informally discussed.

The visiting members were given an opportunity of seeing the work of the Nebraska Station, and a luncheon was tendered them by the Lincoln Commercial Club. Director E. A. Burnett was elected president for the ensuing year, and E. C. Chilcott, reelected secretary. Manhattan, Kansas, was chosen as the place of holding the next summer meeting.

Society for Horticultural Science.—At the Cornell meeting of the society, June 27 and 28, W. T. Macoun spoke on The Relation of Winter Apples to Hardiness of the Tree. To withstand a test winter at Ottawa, a tree or shrub must ripen its wood early. Winterkilling is liable to be more severe after a season when the growth has been strong than when it has been short. The more moderate the climate where a variety originates, the less resistant is it to winterkilling. The hardiest varieties of apples are those that have originated in Russia and are summer or autumn varieties. This is because they ripen their wood most thoroughly, whereas winter varieties continue growth later in the season. The basis for the production of the desired winter apple for the North should be a variety which has withstood test winters in a similar climate and is also the latest keeper of such varieties.

William Stuart presented a general discussion of the use of anesthetics in the forcing of plants, and summarized his own experiments with rhubarb. (See E. S. R., 17, p. 250.)

In a paper on Pollination Methods, S. W. Fletcher presented a symposium of his own experience and that of a considerable number of other plant breeders. The ideal time to emasculate blossoms is as late as possible before the anthers dehisce, but may be done when the buds are still quite small. If complete accuracy is not essential, and when working on blossoms that do not mature stamens and pistils simultaneously, the blossoms need not be emasculated. In crossing, select mature trees of moderate growth and perfectly sound. On such trees select buds borne high up on the outside of the tree on well-nourished branches on the side of the tree opposite from the direction of severe prevailing winds. As to the instruments for emasculating, in the majority of cases a small scalpel is to be preferred, especially for the stone and pome fruits. As to the location of the cut, the majority opinion is that it should be made at the insertion of the stamens above the nectary, though the author

himself prefers to make it as high up as possible. The safest time to pollinate is near the beginning of the receptive condition of the pistils or perhaps twenty-four hours before. A receptive stigma usually glistens when it catches the sunlight and in most fruits it is beginning to be slightly brownish. Brush pollinating is often most practicable when many blossoms must be pollinated in a short time. For our common trees, however, some workers use the thumb or forefinger. As to the percentage of successes, seven pollinators of experience placed their averages variously at from 50 per cent down.

Some phases of pollination were presented by N. O. Booth. The period during which fresh pollen is available for study may be lengthened by forcing twigs in the laboratory. If pollen is taken from the orchard at the normal blooming season it is advisable to take twigs with still unopened buds and let them open indoors. This assures freedom from foreign pollen. Very few apple varieties have the pollen all good and none so far all bad, most varieties showing different proportions of mixed forms. Pollen from the same tree may differ with the condition of the tree. Tompkins King and Esopus Spitzenburg among others have notably weak pollen and are successfully raised only in neighborhoods where conditions are favorable for pollen production. Varieties with particularly strong pollen, as Jonathan and Ralls, are of wide adaptation and are often liable to overbear, the fruits being consequently undersize.

F. W. Card presented a symposium of experience as to the advantage of double-working apples on vigorous stocks. The value of top-working to increase hardiness of stock in a trying climate is unquestioned. It markedly reduces injury from certain diseases. Northern Spy, especially, promises to reduce injury from the woolly aphis in the South. Weak-growing varieties are benefited by the practice. Early bearing can be promoted by top-working on a weak stock, although at the expense of productiveness and doubtless of longevity. But for ordinary varieties in favorable regions the advantages of top-working are outweighed by the disadvantages.

Earle J. Owen discussed The Importance of Selection in Plant Breeding, citing several striking examples of its application.

L. C. Corbett raised the query, What is to be the Future Application of the Term Horticulture? To the already recognized subdivisions of horticultural interests in America, namely, olericulture, pomology, floriculture, and landscape gardening, the author would add plant breeding and plant propagation. Under the latter head is comprised nursery work and the increasing of annual plants from seed or from herbaceous cuttings.

H. J. Eustace gave an account of investigations on apple decays in commercial cold storage. Several varieties of apples were inoculated with black rot, brown rot, bitter rot, soft rot or blue rot, and a species of Alternaria, and at once put in cold storage at a constant temperature of 30 to 32° F. At the end of two months none of these diseases had developed except the soft or blue rot. Later, when the inoculated fruit was taken out of storage, the other diseases also developed, showing that the low temperature of the cold storage simply retarded the fungi in their development but did not destroy them. In another experiment, where the temperature ranged from 37 to 56°, decays developed slowly, except the soft rot; but when the temperature ranged from 54 to 65.5° all decays developed and in most cases very rapidly. Peaches similarly inoculated and held in cold storage two weeks developed decays in about one-half of the specimens.

Prof. W. R. Lazenby read a paper on the use of colored cloth in shading plants. Cabbage, tomato, lettuce, and geranium plants, as well as seeds of corn, peas, beans, and radishes were grown under ordinary white cheese cloth shade, as well as cheese cloth colored black, red, blue, and yellow. Corn and bean seeds came up most readily under the black cloth, but the plants under both black and red cloth soon

began to show weakness and decline in rate of growth. The early shading of rhubarb with black cloth gave excellent results in lengthening the petiole and diminishing the size of the leaf blade. On the whole, the observations indicate "that black bunting may be profitably used as a shade in early spring and possibly at a later date on certain crops, like celery, cauliflower, etc. It may also hasten the maturity of certain vegetables, like tomatoes, when used after the plants or fruit are well developed." Other benefits from shading are the protection of the plants from frost, and from certain insects, like the radish fly and beetle.

H. P. Gould described the recording of phenological data for pomological uses as carried on by the U. S. Department of Agriculture for several years past.

Abstracts of L. H. Bailey's address on The Field for Experiment in Horticulture and John Craig's paper on Plant Growing by Artificial Light were not obtained.

Forestry Instruction at Armstrong College.—The forestry branch of Armstrong College, Newcastle-on-Tyne, has been given charge of the local management of Chopwell Woods in the county of Durham. These woods are within a few miles of the college and contain nearly 900 acres of larch, spruce, Scotch pine, oak, ash, and other trees, most of which were planted about 50 years ago. A house is being built in the woods for the college lecturer in forestry, and arrangements made for the holding of short courses for practical foresters. It is believed that this addition to the college will make it one of the most favorable centers for forestry instruction in the United Kingdom.

Macdonald College.—The New York *Evening Post* is authority for the statement that Sir William Macdonald has completed arrangements for transferring the new Macdonald College, at St. Anne de Bellevue, near Montreal, which was established by him, to McGill University. The property is valued at between $2,000,000 and $3,000,000, and has a fund amounting to $2,000,000. It is the founder's wish that it should rank as a college of McGill University.

A New Sugar School.—A professional sugar school was opened at St. Ghislain, Belgium, May 1, 1906, with 12 students in attendance. The course of study includes the following subjects: Physics and general chemistry; analytical and applied chemistry; sugar technology, sugar chemistry, and sugar legislation; general mechanics and industrial electricity; mathematics; sugar accounts; geometrical drawing, industrial drawing, and industrial economy. The course covers two years and leads to a diploma.

Irish Scholarships in Agriculture.—The Department of Agriculture and Technical Instruction for Ireland offers scholarships at the Royal College of Science in Dublin and the Albert Agricultural College, Glasnevin, each scholarship to include free tuition for one year, a third-class railway fare to and from college, and either a maintenance allowance of $5.00 a week if in attendance at the Royal College of Science or free board and lodging at the Albert Agricultural College. The scholarships are good for one year, but may be renewed for two or three years to enable students to complete the agricultural course.

A Summer School Course in Children's Gardens.—The New York University is conducting a six weeks' course in children's gardens in connection with its summer school, which opened July 2. The course is under the direction of Henry Griscom Parsons, Assistant Director of Children's Gardens in New York, and about 25 young women have been enrolled.

School Gardens in England.—According to a recent report in the *Agriculturist Economist* there are in Surrey County, England, under the control of the Surrey Education Committee, 61 sets of children's gardens attached to the elementary schools, where no less than 1,000 boys are being taught practical gardening. Tools and seeds are supplied and a capable instructor is employed.

Miscellaneous.—The degree of doctor of science was conferred upon Dr. A. C. True, director of this Office, by Wesleyan University.

Dr. D. E. Salmon, formerly chief of the Bureau of Animal Industry of this Department, has accepted an offer of the Government of Uruguay to organize a bureau of animal industry for that government, and will proceed to that country next December.

Prof. William Schlick, of St. John's College, Oxford, has been constituted professor of forestry.

W. P. Wright, horticultural instructor in Kent County, has been appointed superintendent and lecturer of the horticultural department of the Southeastern Agricultural College at Wye, England. A definite course along this line is to be established at the college.

The Cuban Government has recently instituted an official publication of the secretary of agriculture, industry, and commerce, entitled *Boletin Oficial de la Secretaria de Agricultura, Industria y Comercio*, Vol. I, No. 1 of which has been received. It is announced that the experiment station will be a contributor to this publication, and the first number gives the full organization of the station, which includes 21 persons.

Le Bambou is the name of a new French monthly publication, which is to be devoted entirely to the study, culture, and uses of bamboo. It is published at Mons, Belgium, by the editor, Jean Houzeau de Lehaie. The first number was issued January 15, and contains 40 octavo pages.

The Rhine Province Dairy Institute at Zülpich was removed to Griethausen, near Cleve, on April 1, 1906.

O

EXPERIMENT STATION RECORD.

VOL. XVII. AUGUST, 1906. No. 12.

The second session of the Graduate School of Agriculture, held at the College of Agriculture of the University of Illinois, July 2-28, was a marked success from beginning to end. As is generally known the graduate school has been adopted by the Association of American Agricultural Colleges and Experiment Stations, and the colleges represented in that organization tax themselves for its support. In its general management of the enterprise, the association is represented by its standing committee on graduate study, of which Director L. H. Bailey, of Cornell University, is chairman. The University of Illinois very generously extended an invitation to hold the school under its auspices this year, and its success was due in no small measure to the excellent facilities afforded by the College of Agriculture and the efforts of its personnel. Dr. A. C. True, Director of the Office of Experiment Stations of the U. S. Department of Agriculture, was again selected as dean of the school, and Prof. Eugene Davenport, dean of the College of Agriculture of the University of Illinois, acted as registrar. Courses were given in agronomy, horticulture, plant physiology and pathology, zootechny, and plant and animal breeding, with special reference to the production of plants and animals suited to the conditions in the Mississippi Valley and the Great Plains. These included lectures and seminars, but no laboratory exercises.

The faculty consisted of 35 of our leading agricultural teachers and investigators, including 5 officers of the U. S. Department of Agriculture, 12 members of the faculty of the College of Agriculture of the University of Illinois, and 18 professors and experts from 16 other agricultural colleges and experiment stations. Aside from these there were several outside men who lectured at the school, among whom were the statistician of the Union Stock Yards at Chicago, representatives of a large commission house in Chicago and of Swift & Co., Maj. David Castleman, who spoke on the breeding of saddle horses, and Mr. N. H. Gentry, the famous breeder of Berkshire pigs.

The total enrollment of the school was 131, of whom 91 were classed as students. These came from 34 States and Territories. Hungary was represented by a professor from the University of Budapest, and

there were three students from India. In addition, there were a considerable number of persons who came as visitors, to attend the exercises for a few days, who were not registered. The attendance, therefore, considerably exceeded that of the previous session, at Ohio State University, at which 75 students were registered.

The opening exercises of the school were held on the evening of July 4, when the school was welcomed to the University by Dr. T. J. Burrill, vice-president of the University. Prof. L. H. Bailey presided and made an address in which he pointed out the need of a comprehensive system of agricultural education comprising institutions or departments for research, graduate study, college courses, extension work, and secondary and elementary courses. The graduate school is needed to aid in the more complete establishment of such a system and to stimulate workers in our agricultural institutions to more thorough study and research.

Dr. A. C. True gave a short history of the graduate school and pointed out the great development of agricultural education and research in this country since the first session of the school was held four years ago. He also called attention to the pressing need for more trained workers in different branches of agricultural service. The claim was made that the battle for adequate recognition of agriculture in our higher institutions of learning is essentially won and that our leading educators are convinced that agriculture in some form should constitute part of the industrial element of public school education. It was pointed out that so great is the public interest in agricultural education and research that funds are coming to our agricultural institutions fully as fast as they can be utilized, and that a very great responsibility is being laid on our agricultural teachers and scientists to make the best use of the money put in their hands.

A paper by Dr. H. W. Wiley, Chief of the Bureau of Chemistry of the U. S. Department of Agriculture, was also presented, in which the meager opportunities for study along agricultural lines in preparation for the doctor's degree at our leading universities were shown. These were contrasted with the wider opportunities for such work offered in the German universities and the greater extent to which advanced study in agricultural lines is encouraged. Dr. Wiley declared that "there are no problems of a strictly scientific character which at the present time have more intimate relations to the welfare of the people than those which are connected with agriculture. The field of research also in this region is more fruitful, the number of problems greater, and the opportunities for discovery wider than in almost any other field of scientific investigation. The establishment of agricultural colleges and experiment stations is giving proper training to a vast body of young men, many of whom ought to enter the university and continue

the studies of their college days. . . . What the friends of agriculture should ask is that in the future our great universities should recognize agricultural science as one of the leading branches to which attention should be paid in graduate studies."

Several conferences and informal meetings were held during the session of the school, and a National Association of Dairy Instructors and Investigators was formed. A conference for the discussion of general questions relating to the organization of agricultural education and research was held July 7. Dean Davenport outlined the organization of the College of Agriculture of the University of Illinois. The system followed there involves the division of authority and work in such a manner that definite responsibility is laid on officers in the several departments and full credit is given for each man's share in the work. Questions involving "team work" are discussed at meetings of the workers, and every effort is made to secure full agreement on plans before their execution is attempted. In order to secure financial and moral support for the college and station the farmers' organizations throughout the State are taken into confidence, and the responsibility for the proper maintenance of the institution is laid on their shoulders.

Professor Bailey argued in favor of the establishment of regular provision for agricultural studies leading to the doctor's degree in our universities and would make this a matter to be controlled by the university rather than by the college of agriculture. He also favored the simplification of degrees and would have Ph. D., M. S., and B. S. (or M. A. and B. A.) the only degrees to be conferred in course. This suggestion met with much approval from members of the graduate school.

Dr. W. H. Jordan, director of the New York State Experiment Station, spoke very earnestly of the need of more thorough scientific research along agricultural lines, and impressed his hearers with the great importance of maintaining the strictest integrity in making and recording agricultural investigations.

Dr. W. O. Thompson, president of Ohio State University and one of the founders of the graduate school, gave a brief account of the origin of the school, and expressed his strong belief in its value as an aid to broadening and strengthening our system of agricultural education. He predicted that it would have a career of increasing success and usefulness. Dr. Brown Ayres, president of the University of Tennessee, spoke from the standpoint of one interested in general educational advancement, and emphasized the importance of the movement for the development of a thorough system of agricultural education.

A conference on extension work in agriculture was held July 21, at which great interest in this feature was developed. Resolutions

favoring the aid of the Office of Experiment Stations in this direction were adopted.

A meeting of dairy instructors and investigators July 17–19 resulted in the formation of a national organization, as mentioned above. At this meeting a regular programme was presented, covering the whole range of dairy teaching and experimentation. The papers and discussion brought out the urgent need of scientific investigation to solve many practical problems in dairying and in the feeding of dairy cattle. Emphasis was placed on the demand for more and better trained men in dairy work, and on raising the standard of dairy instruction. Prof. R. A. Pearson, of Cornell University, was elected president of the association, C. B. Lane, of the U. S. Department of Agriculture, secretary-treasurer, and committees were appointed upon various topics.

Informal meetings were held several evenings at which questions relating to various phases of agricultural education were discussed. Among these were the methods of teaching agronomy, the organization of secondary and elementary courses in agriculture, and the science of agriculture as a basis for the organization of a system of agricultural education. These meetings were to some extent a continuation of the daily sessions and seminars. This atmosphere of discussion of matters of fundamental importance in agricultural education and research was probably one of the most beneficial features of the school.

On Saturday, July 14, about 70 members of the school visited the estate of the Funk Bros., near Bloomington, Ill., comprising about 25,000 acres, where crop and animal production on a large scale was seen under the best conditions, as well as considerable experimental work in breeding oats and corn.

When news came of the death of Hon. H. C. Adams, the school adopted resolutions expressing their appreciation of the services rendered to the cause of agricultural education and research by Mr. Adams, in securing the passage of the act "which will forever bear his name and associate him in the minds of our people with Senator Morrill, of Vermont, and Representative Hatch, of Missouri, through whose wise statesmanship our agricultural colleges and experiment stations have been established and maintained."

The interest in the work of the school was well sustained throughout the session. There was considerable going and coming of students, a few even registering during the last week. Even those who stayed only a few days seemed to feel that they had received inspiration and information which made their coming to the school worth while. The students were unanimous in their expressions of the benefits and the broadening influence of the school, and in the general hope that another session might be held two years hence.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

The examination of materials important in agriculture and the industries, J. König (*Die Untersuchung landwirtschaftlich und gewerblich wichtiger Stoffe. Berlin: Paul Parey, 1906, 3. ed., rev., pp. 1100, pl. 1, figs. 352*).—This is the third revised edition of this practical handbook of methods of examination of soils, manures and fertilizers, ashes, feeding stuffs, seeds, milk and dairy products, fats and oils, honey; materials and products of sugar, starch, spirits, beer, and wine making; water, dust and smoke injurious to vegetation, wool, beeswax, lubricants, etc.

New official Italian methods of analysis of fertilizers, L. Sicard (*Ann. École Nat. Agr. Montpellier, n. ser., 5 (1906), No. 4, pp. 300–323*).—The methods adopted by the directors of the agricultural experiment stations and laboratories of Italy in convention held in Rome in July, 1904, are described and critically discussed and compared with other methods for the same purposes. These include general methods of determining moisture, nitrogen, total phosphoric acid, potash, and iron and aluminum oxids, and methods of analysis of special fertilizers, such as superphosphates, aluminum phosphate, Thomas slag, ammonium sulphate, sodium nitrate, and farm manure.

A further note on the determination of phosphoric acid by the citrate method, V. Schenke (*Landw. Vers. Stat., 64 (1906), No. 1, pp. 87–91; abs. in Chem. Centbl., 1906, I, No. 19, p. 1573*).—This is a reply to criticisms of the author's method by F. Mach (E. S. R., 17, p. 731), in which further analytical data in substantiation of the accuracy of the method are reported.

A method of detection and determination of small quantities of iron, A. Mouneyrat (*Compt. Rend. Acad. Sci. [Paris], 142 (1906), No. 19, pp. 1049–1051*).—A colorimetric method based upon the green coloration produced when hydrogen sulphid is passed through an alkaline solution of iron is described. It is claimed that the method is applicable to solutions containing from 1 part of iron to 1,000 parts of solution to 1 part to 100,000, and is more sensitive than the sulphocyanid method, being especially applicable in biological investigations.

Tables for use in nitrogen and protein determinations, F. E. Hepner (*Wyoming Sta. Rpt. 1905, pp. 61–71*).

The determination of nitrogen in milk, M. Popp (*Milchw. Zentbl., 2 (1906), No. 6, pp. 263–268*).—This report of experiments concludes with the following outline for determining nitrogen in milk: Into a short-necked digestion flask are put 10 gm. of milk (measured with a pipette), 25 cc. of pure concentrated sulphuric acid, 1 to 2 gm. of mercury, and some sharp-cornered pieces of glass. After heating gently for 10 minutes, 10 gm. of potassium sulphate is added and the mixture boiled for 30 minutes. After cooling and transferring to the distillation flask, 5 gm. of zinc dust is added and also the necessary sodium hydroxid when the distillation and determination are made in the usual way.

The laboratory book of dairy analysis, H. D. Richmond (*London: C. Griffin & Co., Ltd., 1905, pp. VIII+90*).—This handbook on the composition and analysis of milk is intended for both the dairy manager and the trained chemist.

New rapid method for the determination of fat in milk without the use of acid, N. Gerber (*Rev. Gén. Lait, 5 (1906), No. 14, pp. 318–321*).—In this method, designated the salt method, the same apparatus is used as in the Gerber acid method, but the casein is dissolved by means of an alkaline solution, the exact composition of which is at present secret. Comparative determinations by the salt and acid methods are reported. They show very close agreement.

The salt method, M. Siegfeld (*Molk. Ztg., 20 (1906), No. 14, pp. 371–373*).—The salt mixture used in dissolving the casein in this new Gerber method is said to consist of sodium chlorid, sodium hydroxid, Rochelle salt, and a small quantity of coloring matter.

A solution is made by dissolving 230 gm. of this mixture in 1 liter of water. Eleven cc. of this solution, 10 cc. of milk, and 0.6 cc. of isobutylalcohol are mixed in the acid butyrometer, which is then placed in a water bath at 45° C. for 3 minutes and then centrifuged for 3 minutes. The reported results by the salt method are essentially the same as those by the acid method. The salt method is said to be uninfluenced by the presence of formalin or potassium bichromate in the milk.

On the importance of determining the freezing point in milk analysis, A. A. Bonnema (*Pharm. Weekbl., 43 (1906), No. 18; abs. in Rev. Gén. Lait, 5 (1906), No. 15, pp. 346, 347*).—The average freezing point of fresh cows' milk was found to be —0.555° C., which was increased as much as 0.02° by allowing the milk to stand for several hours or by boiling. Lactic fermentation lowered the freezing point. The importance of cryoscopy in detecting adulteration of milk is discussed.

The detection of cocoanut oil in butter, A. W. Thorp (*Analyst, 31 (1906), No. 363, pp. 173–175*).—The author determines the Reichert-Wollny number in the usual way, then adds 110 cc. of water to the flask, and distills off a second 110 cc. and titrates this with tenth normal sodium hydroxid. The insoluble volatile acids are then dissolved in 100 cc. of 90 per cent alcohol slightly warmed and this is also titrated with the tenth normal soda solution.

The number of cubic centimeters of the tenth normal soda solution required in the 3 determinations were respectively 29.2, 3.1, and 7.6 for normal butter and 8, 4, and 34 for cocoanut oil. The addition of 10 per cent of cocoanut oil to butter increased the third determination to 10.2 and the addition of 90 per cent to 29.1. In no instance did the alcoholic solution show a higher number than 8.4 for pure butter.

Plant lecithin; a preliminary communication, E. Winterstein and O. Hiestand (*Ztschr. Physiol. Chem., 47 (1906), No. 4–6, pp. 496–498*).—From their studies of the lecithin of cereals, lupines, and grasses, the authors are of the opinion that the name lecithin should no longer be applied to the organic bodies containing phosphorus, which occur in plants and are soluble in ether and alcohol, but that they should be termed phosphatides as has been suggested for similar products of animal origin.

Experiments on amino acids, polypeptids, and proteids, E. Fischer (*Ber. Deut. Chem. Gesell., 39 (1906), pp. 530–610*).—The cleavage of proteids yields, in addition to ammonia, albumoses, peptones, and finally amino acids. Albumoses and peptones are complex bodies but the acids are comparatively simple and the study of the chemical structure of proteids has been approached through this group.

The investigations have included synthesis and other studies of such acids, and several new and important methods of working with them and other products of proteid hydrolysis have been evolved. The general purpose of the author's work at present is to unite two or more amino acids to form a complex molecule and in this he has been successful and about 70 such bodies have been produced by his methods. The name polypeptids is proposed for these compounds, which are designated dipeptids, tripeptids, etc., according to the number of acid radicals entering into their structure. A tabular list of polypeptids is given. As a class polypeptids exhibit many

characteristics of proteids and in general it may be said that the author at present believes that albumins are polypeptids as regards structure.

The identification of sugar in mace and in cinnamon, E. SPAETH (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 8, pp. 447–450*).—A controversial article in which the author again states that sugar is a normal constituent of mace and cinnamon and summarizes data regarding its occurrence and estimation.

A new method of estimating organic phosphoric acid in flour and flour products, C. ARRAGON (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 9, pp. 520, 521*).—The proposed method consists essentially in extracting organic phosphorus with alcohol, igniting the residue obtained after evaporation, and determining the phosphorus as magnesium pyrophosphate.

The detection of sawdust in flour and bread, P. PAGANINI (*Gior. Farm. e Chim., 54 (1905), pp. 5–11; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 9, p. 530*).—The method of detecting sawdust depends upon the fact that wood when treated with paraphenylendiamin and acetic acid gives an orange-red color. Neither wheat flour nor corn meal gave such reaction.

The brown deposit found on aluminium vessels in which water has been boiled, C. FORMENTI (*Chem. Ztg., 29 (1905), No. 55, p. 746; abs. in Hyg. Rundschau, 16 (1906), No. 10, p. 557*).—The brown deposit, the author states, is graphite-silicic acid, and is harmless.

METEOROLOGY—WATER.

Report of the meteorological council (*Rpt. Met. Council [Gt. Brit.], 1905, pp. 227, pls. 2, fig. 1, map 1*).—This consists as usual of administrative reports regarding organization and operations (during the year ended March 31, 1905) in marine meteorology, forecasts and storm warnings, climatology, publication, and miscellaneous subjects, with appendixes relating to conspicuous meteorological occurrences in 1904, operations of the office in the 50 years since 1854, lists of logs and other documents received during the year, reports on inspections of meteorological stations, accessions to the library, list of persons and institutions to whom publications are sent, distribution of instruments, and financial statement.

The methods of distribution and the accuracy of weather forecasts are discussed, and it is shown that during the year 1904–5 57 per cent of the forecasts were completely successful, 31 per cent partially successful. The averages for 1895 to 1904 are 55.5 per cent completely successful, 28.2 per cent partially successful. The percentage of successful storm warnings in 1904 was 89.8.

The work of the station of agricultural climatology of Juvisy during 1905, C. FLAMMARION (*Bul. Mens. Off. Renseig. Agr. [Paris], 5 (1906), No. 4, pp. 433–455, figs. 6*).—A record is given of observations on atmospheric pressure, temperature of the air, soil, and underground water, relative humidity, rainfall, sunshine, and radiation, in continuation of those of previous years (E. S. R., 17, p. 440). Studies of the effect of different rays on plants and animals were also made as in previous years. Inconclusive studies of the influence of the moon on the germination and growth of various crops which have been noted elsewhere (E. S. R., 17, p. 532) are recorded.

The general course of the temperature of the air and of the soil at depths of 0.25, 0.5, 0.75, 1, and 1.5 meters was analogous throughout the year. During October, November, December, January, and February there was a series of rising temperatures which increased with the depth in the soil; in May, June, July, and August a series of falling temperatures which decreased with the depth. The temperature curves thus crossed in spring and again in autumn. The mean temperature of the water in wells about 14 meters deep was 11.3° C., 1.6° higher than that of the air, and the annual variation in temperature was 1.4° C.

Meteorological records for 1904 (*New York State Sta. Rpt. 1904, pp. [illegible]–441*).—Tables are given which show the average monthly precipitation since 1882; average

monthly temperature since 1882; tridaily readings of the standard air thermometer during each month of 1904; a monthly summary of maximum, minimum, and standard thermometer readings; and daily readings of maximum and minimum thermometers at 5 p. m. for each month of the year.

Meteorological summary, C. B. Ridgaway (*Wyoming Sta. Rpt. 1905, pp. 76, 77*).—A summary of observations at Laramie, Wyo., on temperature, atmospheric pressure, precipitation, evaporation, and direction and velocity of the wind during the year 1904. The mean temperature for the year was 41.9° F., the highest 83, July 12 and 15, the lowest −16, January 28; the mean barometric pressure was 23.024 in.; the total precipitation was 9.58 in., the mean for the past 10 years being 9.8 in.; the evaporation from May 7 to September 15 was 1.866 ft.

The climate of Naples during the meteorological year 1903–4, E. Annibale (*Bol. Soc. Nat. Napoli, 1. ser., 19 (1905), pp. 65–96*).—Observations on atmospheric pressure, temperature, humidity, precipitation, direction of the wind, cloudiness, and storms are summarized and discussed.

The rainfall régime and crops in Russia, H. Sagnier and E. Tisserand (*Bul. Soc. Nat. Agr. France, 66 (1906), No. 1, pp. 32–38*).—Statements by A. Yermoloff regarding the dependence of crops, particularly wheat, upon the amount and distribution of spring rains, especially in central Russia, and the failure of crops in seasons of deficient or badly distributed rainfall, are reported and commented upon.

Weather forecasting (*Abs. in Rev. Gén. Sci., 17 (1906), No. 8, pp. 350, 351*).—A report by Durand-Gréville to the Belgian Astronomical Society on laws of storm movements in relation to weather forecasting is briefly reviewed, and a plea is made for a better system of weather forecasting in France.

Protection of crops against hail in 1905 by means of cannon and bombs, H. Dufour (*Chron. Agr. Vaud, 19 (1906), No. 7, pp. 198–207*).—The results of the campaign of 1905 are briefly summarized and the present status and possibilities of this method of protection are discussed.

On the construction of isobaric charts for high levels in the earth's atmosphere and their dynamic significance, J. W. Sandström (*Trans. Amer. Phil. Soc., 21 (1906), No. 2, pp. 31–95, pl. 1, figs. 15*).—It is shown how such charts can be constructed from meteorological observations obtained by means of kites and balloons in the free air, and the connection of the charts with the dynamics of the atmosphere is discussed. "It is to be expected that upon such maps we may easily and naturally present our observations and experience as to atmospheric movements and, therefore, it would seem to promise good results if the daily weather predictions could be based upon such maps."

The gases of the atmosphere, W. Ramsay (*New York and London: The Macmillan Co., 1905, 3. ed.; rev. in Chem. News, 93 (1906), No. 2422, p. 199*).—The principal new feature of this edition is a chapter on radio-activity and radio-active gases.

Water and its use for industrial and technical purposes, E. Leher (*Das Wasser und seine Verwendung in Industrie und Gewerbe. Leipsic: G. J. Göschen, 1905, pp. 124, figs. 15*).—A concise treatise on the occurrence, physical and chemical properties, and testing of water, the technology of water for potable purposes, steam boilers, and special technical processes, water storage, and the disposal of sewage.

The culture of anaerobic micro-organisms as applied to water analysis, A. Guillemard (*Ann. Inst. Pasteur, 20 (1906), No. 2, pp. 155–160, fig. 1*).—It is claimed in this article that present methods of bacteriological examination of water are defective in that account is taken only of the number of organisms which develop in the presence of air and that the probably equally important anaerobic organisms not taken into consideration. A method for studying the relation between ic and anaerobic organisms in water is described, especially the apparatus and d to be used in the culture of anaerobic organisms in an atmosphere of hydrogen.

use of copper sulphate in water filtration, H. W. Clark and S. DeM.

GAGE (*Jour. Infect. Diseases, 1906, Feb., Sup. 2, pp. 172-174*).—Investigations are briefly reported which indicate that the use of copper sulphate as a preliminary treatment in the purification of sewage results in a lowering of the efficiency of subsequent filtration and bacterial purification of the filter bed.

On the bactericidal action of copper, H. W. CLARK and S. DEM. GAGE (*Jour. Infect. Diseases, 1906, Feb., Sup. 2, pp. 175-204*).—An account is here given of a series of experiments in which waters were treated with definite amounts of copper or copper sulphate or placed in contact with metallic copper and allowed to absorb an unknown amount of copper. The efficiency of the treatment was measured by its effect on the total number of bacteria and on the numbers of *Bacillus coli* and *B. typhosus* in the water.

The conclusion is reached that the treatment of water with copper sulphate or by storing in copper vessels has little practical value because it is not absolutely effective and is therefore dangerous in the hands of the general user. It was found in some cases that in order to insure the complete destruction of *B. coli* and *B. typhosus* it was necessary to use copper sulphate at the rate of 1 part to 1,000 of water, in which case the water was of a strongly astringent taste and would be repugnant to the user. Allowing water to stand in copper vessels for short periods was occasionally effective in removing *B. coli* and *B. typhosus*. In other cases, however, the very dilute solutions of copper sulphate or colloidal copper absorbed from contact with clean metallic copper appeared to have a decidedly invigorating effect on bacterial activity.

The resistance to decomposition of certain organic matters in sewage, H. W. CLARK (*Jour. Infect. Diseases, 1906, Feb., Sup. 2, pp. 136-138*).—It is shown in this article that a certain small percentage of exceedingly stable carbonaceous and nitrogenous matter accumulates year after year in filters used for ordinary domestic sewage and seriously impairs their efficiency. This material was found to resist nitrification and is believed to be of a carbonaceous rather than nitrogenous nature.

Biological purification of sewage waters, RICHE (*Ann. Chim. Analyt., 11 (1906), Nos. 1, pp. 16-19; 2, pp. 64-69*).—The importance of biological processes as compared with chemical methods is discussed and various methods in which biological processes play a prominent part are considered, especially from the standpoint of disposal of Paris sewage. These include irrigation, and filter bed, septic tank, the Candy (intermittent sprinkling and carboferrite) method of treatment, and others.

A consideration of the difficulties in the way of disposing of the Paris sewage by means of irrigation leads to the conclusion that the only solution of the problem appears to be a combination of bacterial purification and irrigation.

Recent views of the sewage disposal problem (*Engin. Rec., 53 (1906), No. 4, pp. 87, 88*).—This is a brief editorial review of the recent rapid progress in this field, which is ascribed largely to progress in adopting better methods of sewage analysis, which yield fairly comparable results.

It is stated that "the old idea that sewage farming is the best method of disposal was exploded long ago, and the sewage farms still in service are not kept in operation because they afford the most economical method of treatment, as a rule. The rise of intermittent filtration has similarly reached its culmination. It is acknowledged to be the most perfect method of treatment when all conditions are favorable, but it is now known that it is much more expensive than was formerly anticipated, and the character of the effluent which it furnishes is often unnecessarily good for discharge into the body of water receiving the purified sewage. . . .

"Under these circumstances specialists in sewage treatment have been working to ascertain just what methods are best for securing different degrees of purification from the partial clarification resulting from simple sedimentation to the extreme

degree of purification attained with the best intermittent filters under the best operating conditions. . . .

"Along with this recognition of the varying requirements of sewage treatment are many new suggestions concerning the methods to be followed. The most interesting of these to the engineer who has not been following the development of the subject, is the closer connection which is gradually appearing between the principles of water purification and sewage treatment."

Present practice in sewage disposal (*Engin. Rec., 53 (1906), No. 4, pp. 97, 98*).—This is a summary of a paper presented by G. W. Fuller at a recent meeting of the New Jersey Sanitary Association.

The paper emphasizes the desirability of preparatory treatment with raw sewage to remove the sludge, combinations of methods of purification, and treatment of the effluents with copper sulphate or other germicides, and describes comparative tests which have been made by the city of Columbus, Ohio, of various methods of sewage disposal. The preparatory treatment found most effective in these trials was afforded by septic tanks holding an average flow of about 8 hours, followed by the use of sprinkling filters operating at an average rate of 2,000,000 gal. per acre daily.

The collection and preservation of samples of sewage for analysis, S. DEM. GAGE and G. O. ADAMS (*Jour. Infect. Diseases, 1906, Feb., Sup. 2, pp. 139–148*).—Chloroform in amounts of 10 to 25 cc. to each gallon bottle is stated to be a good preservative for samples of sewage which are to be kept for some time before analysis.

SOILS—FERTILIZERS.

Some new properties of soils, J. KÖNIG, J. HASENBÄUMER, and E. COPPENRATH (*Landw. Vers. Stat., 63 (1906), No. 5–6, pp. 471–478*).—This article discusses briefly the effect of steam on soils and the catalytic power and osmotic pressure of soils.

It is shown that by heating 250 gm. of a soil with 3 to 4 liters of water for 3 hours under a pressure of 4 atmospheres the solubility of the mineral constituents was increased to a considerable extent. Similar treatment acts like mercuric chlorid, chloroform, etc., in reducing the oxidizing or catalytic power of soils, which is ascribed to the action of oxydases (catalase) as well as bacteria. A device consisting of a Chamberland-Pasteur filter coated with gelatin rendered insoluble by the action of formaldehyde fumes for study of the osmotic power of soils is described, but no experiments with it are reported.

A study of rock decomposition under the action of water, A. S. CUSHMAN (*Chem. News, 93 (1906), No. 2410, pp. 50–53*).—This is a discussion of this subject based largely upon investigations which have already been noted (E. S. R., 17, p. 301).

Data are presented to show that electrical endosmosis offers an efficient means of separating not only water but also acids or alkalis from slimy, colloidal, and otherwise unfilterable mixtures such as are obtained with very fine rock powders. It is shown that by successive grindings and treatment with an electric current the potash can be removed from orthoclase and other minerals containing potash.

In the experiments reported "definite weights of the rock powders were slimed with a measured quantity of water, and the slime placed inside an ordinary unglazed porcelain cup such as is used for certain common types of bell batteries. An ordinary arc-light carbon was then inserted and the porcelain cup set down inside a glass cylindrical vessel containing distilled water to the depth of 2 or 3 cm. Another carbon electrode was then inserted in the outside compartment. The cell was then connected with a direct current of about 110 volts, the inner or slime chamber being in connection with the positive pole.

"Under the action of electrical endosmosis all the liquid from the anode or slime chamber passed into the cathode chamber, while at the same time, owing to electrolysis, the free alkali passed out in a condition in which it could be easily titrated or otherwise estimated. In the course of a few hours the slime had been transformed

into a hard, comparatively dry cake, while the free alkali had been partially removed. The alkaline liquor in the cathode chamber was then poured out into a beaker and titrated with tenth-normal acid. After resliming the material in the anode chamber with the proper quantity of water, the apparatus was started again. With the conditions under which we were working it was found that about one hour sufficed for each run."

The absorption of potassium by soils, O. SCHREINER and G. H. FAILYER (*Abs. in Science, n. ser., 23 (1906), No. 583, p. 324*).—This is an abstract of a paper presented at the New Orleans meeting of the American Association for the Advancement of Science.

The absorption of potash by soils was studied by the same methods used in case of phosphates and an equation representing the absorption is worked out, which is as follows: $\frac{dy}{dv}=K(A-y)$, in which K is a constant, A the maximum amount of potassium the soil can absorb under the conditions of the experiment, and y the amount it has absorbed when a volume v of potassium solution has passed through the soil. "The removal by water of the absorbed potassium is rapid at first, but the concentration of the percolates soon reaches a constant value, although only a fractional amount of the absorbed potassium has been removed. As far as the observations have been made the solutions obtained by percolating a solution of potassium chlorid through the soil have always been acid."

The absorption of phosphate by soils, O. SCHREINER and G. H. FAILYER (*Abs. in Science, n. ser., 23 (1906), No. 583, pp. 324, 325*).—This is an abstract of a paper presented at the New Orleans meeting of the American Association for the Advancement of Science. The subject was studied by percolating different phosphate solutions through soils of several types in an apparatus especially designed for the purpose and analyzing separate fractions of the solution which passed through. The absorption phenomena are represented graphically, and a differential equation, which is said to quite accurately describe them, is given. It was found that the absorptive capacity for phosphates varied greatly in different soils, being as a rule most pronounced in the clays and loams and less so in the sandy soils.

"The solubility of the phosphate originally present in the soils was also determined by percolating water through the untreated soils in the above-mentioned apparatus. It was found that the concentration of the separate fractions of percolate was practically a constant for each of the soils studied. If this concentration is reduced through any cause, such as the absorption by plants or influx of rain water, the original concentration will be again restored by more of the phosphate of the soil entering into solution. If, on the other hand, the solution is somewhat stronger than the natural concentration for that soil through any cause whatever, such as the application of a soluble phosphate, the concentration is reduced by absorption to the original strength. . . .

"This constancy in the strength of the soil solution, so far as phosphate is concerned, is further shown by the removal by water of the absorbed phosphate, which has been similarly investigated. It was found that the concentration of the separate percolates decreases rapidly until the concentration is reduced approximately to that of the original soil solution. This concentration of phosphate is then maintained with much persistence, although only a fractional amount of the absorbed phosphate has been removed, thus indicating that while the absorbed phosphate is apparently rendered insoluble, it is, nevertheless, slowly but constantly going into the soil moisture and is, therefore, available to plants."

The absorption of phosphates and potassium by soils, O. SCHREINER and G. H. FAILYER (*U. S. Dept. Agr., Bur. Soils Bul. 32, pp. 39, figs. 6*).—A briefer account of the investigations reported in detail in this bulletin has already been noted (see above).

The solubility of phosphoric acid in sugar-beet soils, J. STOKLASA (*Bl. Zuckerrübenbau, 13 (1906), Nos. 1, pp. 1-9; 2, pp. 17-25, pls. 2; abs. in Chem. Ztg., 30 (1906), No. 16, Repert. No. 4, pp. 55, 56*).—The importance of carbon dioxid produced by micro-organisms in the soil and given off by plant roots as a means of rendering the soil phosphates assimilable is discussed.

It is estimated that 1 gm. of a humus soil contains probably 20 to 30 million micro-organisms, which, with a 20 per cent water content and a temperature of 15° C., are capable of producing 50 to 60 mg. of carbon dioxid per day. The most rapid production of carbon dioxid occurs in the soil at the depth of 10 to 40 cm. and amounts during the growing period (150 days) to 112.5 metric centners per hectare (5,010.12 lbs. per acre).

The author's observations indicate that the fine roots and root hairs of sugar beets are capable of producing as much as 960 kg. of carbon dioxid per hectare in 60 days. The carbon dioxid dissolved in water exerts a direct solvent action on the phosphates of the soil.

On the improvement of a soil relatively deficient in magnesia, T. NAKAMURA (*Bul. Imp. Cent. Agr. Expt. Sta. Japan, 1 (1905), No. 1, pp. 30-34*).—In pot experiments with a soil containing 17 times as much lime as magnesia it was found that although there was sufficient magnesia for the growth of barley plants, the addition of magnesia was very beneficial. The most favorable ratio of lime to magnesia was 7:1, provided the magnesia was applied in the form of sulphate.

"Since the best ratio of lime to magnesia for the growth of cereals was found to be 1:1 when magnesia was applied in the form of magnesite, it would have required 333 gm. magnesite per pot in order to attain the above ratio. As the best result was, however, obtained when 78.72 gm. magnesium sulphate were applied per pot, we may conclude that the relative value or agronomical equivalent of magnesium sulphate to magnesite is here nearly 23:100."

Meeting of the fertilizer section of the German Agricultural Society (*Mitt. Deut. Landw. Gesell., 21 (1906), No. 7, pp. 69-74*).—Short accounts are given of the discussion of the following topics: The use of commercial fertilizers in Bavaria, preservation of barnyard manure and its most profitable use, and the influence of deficiency or excess of rainfall on the action of fertilizers.

Investigations by Pfeiffer at Breslau and Immendorff at Jena on the preservation of manures are summarized. The latter show that there is a considerable loss of nitrogen in the stall, and this is greater if the manure is allowed to lie for some time (say 7 days) under the feet of the animals than if it is removed daily. Contact with already fermenting manure apparently hastens the loss of nitrogen. The loss is greater both in the stall and in the heap in warm weather than in cold.

Kainit and superphosphate gypsum used at rates of 1.5 to 2 kg. per 1,000 kg. of live weight of animal were practically worthless. The use of sulphuric acid and superphosphate gypsum in amounts (3 kg. per 1,000 kg. live weight) giving a permanent acid reaction quite effectively prevented loss of nitrogen, but this is not practicable on account of excessive cost. The use of peat litter is the most effective means of preventing loss. In the experiments reported the loss of nitrogen was reduced to 7.3 per cent. The loss of nitrogen was less when the liquid manure was separated from the solid than when the two were mixed.

The sale of sheep manure, F. DE BARRAU (*Jour. Agr. Prat., n. ser., 11 (1906), No. 11, pp. 341-343*).—A brief note on local trade in this article and on its composition and fertilizing value. The following analysis is reported: Nitrogen (organic and ammoniacal) 1.36 per cent, phosphoric acid 0.26 per cent, potash 1.17 per cent, water 60.33 per cent. The manure is valued especially by viticulturists. Attention is called to the danger of impoverishing the farm by selling this material without returning an equal amount of fertilizing material in some other form.

Fertilizers on cereal crops grown in rotation, C. E. THORNE (*Ohio Sta. Circ. 54, pp. 15*).—This circular summarizes the results of 12 years' experiments on the station farm at Wooster, 11 years on the test farm at Strongsville, in northeastern Ohio, and 2 years each on the test farms at Germantown in southwestern Ohio and Carpenter in southeastern Ohio.

The crops grown at Wooster and Strongsville were a 5-year rotation of corn, oats, wheat, clover, and timothy; on the other farms a 3-year rotation of wheat and clover. The fertilizers used were phosphoric acid in form of acid phosphate alone and combined 2 by 2, and all 3 together with potash in form of potassium chlorid and nitrogen as nitrate of soda. Experiments at Wooster with barnyard manure untreated and treated with gypsum, floats, and acid phosphate are also briefly reported.

The results show that corn and oats responded profitably to moderate applications of phosphoric acid on the soils experimented with, which are believed to be typical of the soils of the State in general. The addition of potash to phosphoric acid in the fertilizer sometimes, but not always, gave a profitable increase in the yield of corn and oats.

The use of potassium seems to be especially indicated in regions where hay and straw, as well as grain, have been sold off the land for a considerable period, or where tobacco, cabbage, or other crops, in which the entire plant is taken off the farm, have been extensively grown.

"The complete fertilizer, containing nitrogen and potassium, as well as phosphorus, nearly always produced a larger total increase of corn and oats than any partial fertilizer; but when the nitrogen and potassium were purchased in commercial fertilizers their cost was usually greater than the additional gain, over that produced by phosphorus alone, was worth.

"The complete fertilizer invariably produced a larger increase in the wheat crop than that given by any partial fertilizer, and on the hard-run land at the main station, which has been exhaustively cropped with cereals for 60 to 75 years, the additional increase in the wheat and hay crops resulting from the use of the complete fertilizer more than offset its largely increased cost, leaving a larger net gain than that obtained from any partial fertilizer; but on land that had been resting in pasture for many years or on land in a high state of fertility the increase from the complete fertilizer has not yet been sufficient to justify its use, if the nitrogen and potassium must be purchased in commercial carriers; but in farm manure nitrogen and potassium may be secured practically without cost, and these experiments have shown that such manure may be made as effective a carrier of these elements of fertility as the most active forms in which they are found in commercial fertilizers." The barnyard manure treated with acid phosphate or floats was an especially effective fertilizer.

Inoculation of leguminous plants (*Jour. Bd. Agr.* [*London*], *12* (*1906*), *No. 11, pp. 641–659, figs. 3*).—This is an account of tests by 13 agricultural colleges and experiment stations in Great Britain of Hiltner's nitragin and Moore's inoculating material distributed by the Board of Agriculture. The general plan of the experiments include laboratory tests with sterilized soil or sand, pot cultures in unsterilized soils from various sources, and tests in accord with actual agricultural or horticultural practice, including inoculation of areas of field soil of various sizes.

"As a result of all the reported experiments, it seems evident that the cultures used were not uniform; it is not possible, however, to determine the extent to which the failures are to be attributed to this cause. It seems, however, from the positive results recorded that not only are these cultures sometimes able to produce nodules on the roots of plants new to a neighborhood, but that even in cases where the leguminous crop had been grown in the previous year benefit may be derived from inoculation.

"It is quite evident that the subject of plant inoculation in this country has not yet passed the experimental stage, and more work is required before one can feel at all justified in recommending either method for adoption on a field scale; nevertheless, the positive results obtained may lead farmers to hope that in the future benefit may be derived, in some instances at least, from the treatment of the soil or the seed before sowing, with inoculating materials preparatory to growing leguminous crops."

The fixation of atmospheric nitrogen (*Engineering [London], 81 (1906), No. 2090, pp. 89, 90; Sci. Amer. Sup., 61 (1906), No. 1573, pp. 25205–25207*).—This is a review of investigations on this subject, including in some detail the recent developments along this line in Norway and a list of references to the more important literature of the subject.

Fixation of atmospheric nitrogen, P. A. Guye (*Electricien, 1905, Dec. 30, Sup., p. 417; abs. in Rev. Sci. [Paris], 5. ser., 5 (1906), No. 12, pp. 376, 377*).—Investigations on this subject are briefly reviewed, and it is pointed out that the progress made toward the development of commercially successful methods must be based upon scientific investigations and theoretical considerations.

The fixation of atmospheric nitrogen (*Rev. Gén. Sci., 17 (1906), No. 6, p. 260*).—It is stated that the method of producing expanded arcs used by Birkeland and Eyde was first described by Plücker in 1861.[a]

On the utilization of atmospheric nitrogen, W. Löb (*Umschau, 10 (1906), No. 14, pp. 265–271, figs. 7*).—An illustrated account is given of the Birkeland and Eyde process as carried out at Notodden.

The manufacture of nitric acid at Notodden, L. Grandeau (*Jour. Agr. Prat., n. ser., 11 (1906), No. 10, pp. 296–299, figs. 4*).—The plant and methods used at this place for the preparation of nitric acid from atmospheric nitrogen by the Birkeland and Eyde process are described.

The factory at Notodden, Norway, for the manufacture of nitrate, L. Grandeau (*Jour. Agr. Prat., n. ser., 11 (1906), No. 11, pp. 328–330, figs. 2*).—Further descriptive details regarding the factory established at this point for the manufacture of nitrate from atmospheric nitrogen by the Birkeland and Eyde process.

The electric furnace of Birkeland and Eyde, L. Grandeau (*Jour. Agr. Prat., n. ser., 11 (1906), No. 9, pp. 265–268, figs. 3*).—The principles of construction of this furnace are explained and statistics are given as to the extent to which it is being used in Norway in the preparation of nitrogen compounds from the air.

Calcium cyanamid (*Mark Lane Express, 94 (1906), No. 3883, Fert. and Feed., p. 11*).—It is stated that the German Agricultural Society announces that it is now prepared to furnish this material, with 19 per cent nitrogen, in limited quantities for fertilizer tests at a cash price of about \$53.53 per ton, in bags f. o. b.

Nitrogen and nitrogenous fertilizers, P. G. Wicken (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 3, pp. 252–256*).—This article explains briefly the different forms in which nitrogen occurs and discusses the fertilizing value of the nitrogenous fertilizers available for use in West Australia, including nitrate of soda, nitrate of potash, ammonium sulphate, soot, blood manure, bone dust, tankage, guanos, urine and night soil, oil cake, wool waste, decomposed hair and lime from tanneries and fellmongeries, barnyard manure, and seaweed.

Production of nitrate, R. E. Mansfield (*Mo. Consular and Trade Rpts. [U. S.], 1906, No. 305, p. 53*).—The exports of nitrate from Chile to different countries during the year 1904 are given, the total being 740,869 tons, valued at \$52,847,132.

The use of ammoniacal gas liquor as a fertilizer, C. Dusserre (*Ann. Agr. Suisse, 6 (1905), No. 8, pp. 333–335; Bul. Mens. Off. Renseig. Agr. [Paris], 5 (1906), No. 2, pp. 183–185*).—Experiments with a liquor obtained from the gas works of Morges containing from 0.37 to 0.45 per cent of nitrogen, mostly in form of ammonia, but also containing small amounts of sulphid, cyanid, sulphocyanid, etc., are reported.

[a] Ann. Phys. [Poggendorff], 113, p. 252.

The material was applied to grass lands in connection with superphosphate, 500 kg. per hectare (445 lbs. per acre), and potash salts, 300 kg. per hectare (267 lbs. per acre) at rates of 5,000 to 15,000 liters per hectare (about 3,300 to 9,900 gal. per acre) on March 20 and June 8, before and after the first cutting of grass. The smaller application produced very little increase in yield. The larger application produced sufficient increase in yield to pay the cost of transportation and distribution. The addition of sulphate of iron, 500 kg. per hectare (445 lbs. per acre) further increased the yield and completely destroyed mosses in the grass. The use of the gas liquor resulted in the disappearance of leguminous plants from the herbage, but favored the development of the graminæ. The first application of the liquor burned the grass more or less, but it promptly recovered from this injury.

The general conclusion reached was that farmers in the vicinity of gas works may use this material with advantage if they can secure it free of cost. It may be applied with advantage during the winter on grass lands or on uncultivated land either directly or in mixture with liquid manure. Since it contains only nitrogen, it should be supplemented with phosphatic, potassic, and calcareous fertilizers. If applied directly during the summer it may seriously injure plants, but it may be safely used in mixtures with soil or compost.

Bone products, J. C. McNally (*Mo. Consular and Trade Rpts., 1906, No. 305, p. 155*).—A brief note is here given on the composition and fertilizing value of raw and degelatinized bone meal and precipitated bone phosphate. The use and value of the precipitated phosphate as a feeding stuff is also referred to.

Phosphate rock production, E. O. Hovey (*Amer. Fert., 24 (1906), No. 3, p. 21*).—Statements from advance reports of the U. S. Geological Survey are cited showing that the marketed production in 1905 probably exceeded 600,000 long tons as against 530,571 tons in 1904. There was a marked increase in production in Florida and Tennessee and a smaller increase in South Carolina. The average price of phosphate was higher in 1906 than in 1905 due to increased demand in Europe.

Potash as a fertilizer, P. G. Wicken (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 5, pp. 422–424*).—A concise summary is here given of the principal facts relating to this subject.

Analyses of commercial fertilizers, M. A. Scovell et al. (*Kentucky Sta. Bul. 121, pp. 83–153*).—Analyses and valuation of 421 samples of fertilizers inspected during the spring of 1905 are reported.

Analyses of fertilizers, C. A. Goessmann (*Massachusetts Sta. Bul. 107, pp. 42*).—This bulletin gives market values of fertilizing ingredients and reports analyses of licensed fertilizers collected in the general market and miscellaneous fertilizing materials sent to the station for examination, including wood ashes, lime ashes, cob ashes, cotton-seed meal, Peruvian guano, meat and bone, tankage, factory waste, kiln-dried pulverized sheep manure, sheep manure, soils, muck, and complete fertilizers.

Analyses of fertilizers and insecticides, C. A. Goessmann (*Massachusetts Sta. Bul. 109, pp. 28*).—This bulletin includes notes on the taking of samples for analysis, instructions to manufacturers and dealers in commercial fertilizers, a discussion of trade values of fertilizing materials for 1906, and analyses of miscellaneous fertilizing and insecticide materials.

The list includes wood ashes, cotton-hull ashes, lime ashes, refuse ashes, nitrate of soda, cotton-seed meal, new process linseed meal, dried blood, high grade sulphate of potash, carbonate of potash, muriate of potash, double manure salts, kainit, dissolved boneblack, superphosphate, dissolved bone, ground bone, tankage, dry ground fish, carbonate of lime, prepared lime, cotton waste, cotton-seed compost, rotted cotton waste, damaged cocoa, glue refuse, leather dust, bone soup, refuse from wool washings, factory refuse, muck, peat, mud from the decomposition of seaweed, granulated tobacco stems, Peruvian guano, pigeon manure, complete fertilizers, soils, Paris green, arsenate of lead, and other insecticides.

Analyses of commercial fertilizers, P. SCHWEITZER and R. M. BIRD (*Missouri Sta. Bul. 66, pp. 8*).—This bulletin contains a report of analyses of commercial fertilizers collected during the fall of 1904 and the spring of 1905, as well as a financial statement of the receipts and disbursements of the fertilizer control fund for the year ended December 31, 1904.

Analyses of commercial fertilizers, P. SCHWEITZER and R. M. BIRD (*Missouri Sta. Bul. 70, pp. 11*).—This bulletin reports analyses of commercial fertilizers collected during the fall of 1905, and gives a statement of receipts and disbursements of the fertilizer control fund for the year ended December 31, 1905.

Commercial fertilizers, W. W. MILLER and N. W. LORD (*Offic. Rpt. Sec. Ohio Bd. Agr. on Com. Ferts., 1905, pp. 100*).—The results of inspection of fertilizers in Ohio during the year 1905 are given, with statements regarding the fertilizer control and the valuation of fertilizers, and the text of the State fertilizer law.

Licensed commercial fertilizers, 1906, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Bul. 134, pp. 1-17, 24-26*).—Analyses of 22 brands of fertilizers licensed for sale in Wisconsin during 1906 are reported, with a brief general discussion on the purchase, valuation, and use of commercial fertilizers, and the text of the State fertilizer law.

Fertilizers in Japan (*Bd. Trade Jour. [Gt. Brit.], 1906, Jan. 4; abs. in Jour. Soc. Chem. Indus., 25 (1906), No. 2, p. 84*).—Statistics are given showing the extent and increase of use of fertilizers in Japan, especially of oil cakes.

The value of the fertilizers imported into Japan during the first 6 months of 1905 is reported to have been 12,976,352 yen ($6,462,223.30). Of this amount 7,265,109 yen ($3,618,024.28) was paid for oil cake, 638,217 yen ($317,832.07) for ammonium sulphate, 1,179,304 yen ($587,293.39) for calcium phosphate, and 636,997 yen ($317,224.51) for sodium nitrate. The oil cake comes from China, one-third of the nitrate from the United States, and the remainder from Chile and various other countries, the calcium phosphate and ammonium sulphate from the United Kingdom. There are several chemical factories at Osaka which produce fertilizers, especially ammonium sulphate.

Artificial fertilizers, P. G. WICKEN (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 1, pp. 7-18*).—This article discusses especially the prices and value of the fertilizing materials available in West Australia, and gives formulas for fertilizer mixtures for various kinds of crops, with directions for their application. The draft of various crops on the fertilizer constituents of the soil is also explained.

AGRICULTURAL BOTANY.

Plant breeding, L. H. BAILEY (*New York and London: The Macmillan Co., 1906, pp. XIV+483, figs. 48*).—This is a fourth edition of the author's work on plant breeding, which first appeared in 1895 (E. S. R., 7, p. 562).

The most marked changes in this work are to be found in chapter IV, which has been wholly rewritten and which gives a résumé of the investigations of de Vries, Mendel, and others, and in chapter V, which gives accounts of current plant-breeding practice. This last chapter summarizes the work of Burbank and Keeney, and the investigations of the experiment stations and of this Department along this line. A chronological bibliography of references to such literature as English-speaking horticulturists would be most likely to find completes the volume. The bibliography embraces something over 100 pages and is brought down to 1905.

On the correlation between calcium salts and the assimilation of nitrate nitrogen, V. V. YERMAKOV (*Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 4, pp. 403-431*).—The formation of ammonia and oxalic acid when nitric acid acts on glucose suggested to the author the possibility of a similar reaction taking place in plants during the assimilation of nitrate nitrogen, whereby the ammonia

serves for the synthesis of albumin and the oxalic acid, precipitated by the calcium, remains without further influence. If this hypothesis were true, in the absence of calcium salts the oxalic acid formed would not be neutralized, and, being injurious to plants even in small quantities, would hinder the assimilation of the nitrate nitrogen.

To determine this subject the author carried out 3 series of experiments with leaves of grapes, *Paulownia imperialis*, and *Ailanthus glandulosa*. In these experiments the author used one side of the leaves of grapes and Paulownia and the leaflets on one side of the rachis of Ailanthus, the other portions remaining as a check. The nitrate nitrogen was determined by the Schultze-Tiemann method.

In the first series of experiments some of the leaves were placed for 24 hours in a 0.2 per cent solution of calcium nitrate and others in a 0.2 per cent solution of potassium nitrate. At the end of the experiments only traces of nitrate nitrogen were found in the leaves receiving the calcium solution, while the leaves placed in the potassium solution contained an appreciable quantity of nitrate nitrogen. This seems to indicate that in the leaves receiving calcium the nitrate was consumed by the plant.

In the second series of experiments the leaves were placed in a 0.2 per cent solution of potassium nitrate and were then cut in halves, some of which were used as controls while others were placed in various solutions. The results show that in the leaves which had received calcium salts the nitrate disappeared, being assimilated, while where no calcium salt was present the nitrate remained unaffected. The author concludes from this that calcium is indispensable for the assimilation of nitrate nitrogen.—P. FIREMAN.

The morphology and biology of nitrogen-assimilating organisms, L. LUTZ (*Les microorganismes fixateurs d'azote. Paris: J. Lechevalier, 1904, pp. 187, figs. 19; abs. in Centbl. Bakt.* [*etc.*], *2. Abt., 15* (*1905*), *No. 15-16, pp. 477, 478*).—The author gives a critical review of the literature relating to nitrogen assimilation by bacteria and other micro-organisms and practically gives a summary of the present status of knowledge on the morphology and biology of nitrogen-assimilating organisms.

After a historical résumé, the author gives an account of the attempts to cultivate the nitrogen-fixing organisms, particularly the experiments of Winogradski and Beijerinck, and of the cultures known as Alinit. The general conditions for fixation of nitrogen in the soil and factors limiting it are described, after which especial attention is given the morphology and physiology of the tubercles on the roots of the Leguminosæ and of the organisms which they contain. The literature on the culture of these organisms is reviewed at considerable length, and suggestions are given for the growth of the bacteria in nitrogen-containing and nitrogen-free media. The biological forms and physiological characteristics of the organisms are described and the various factors controlling nitrogen assimilation are reviewed. Accounts are given of various attempts in the utilization of the bacteria by applying them to practical use in the field, particularly on the use of pure cultures.

In addition to the Leguminosæ the author shows that tubercles of a similar nature occur on the roots of alders, Eleagnus, Podocarpus, Myrica, Datisca, etc.

A chapter is devoted to the fixation of free atmospheric nitrogen through symbiosis between algæ and bacteria by mosses, etc.

An extended bibliography of literature completes the volume, about 500 titles being cited.

Effect of differences in solar radiations on the transfer of albuminoids in wheat, J. DUMONT (*Compt. Rend. Acad. Sci.* [*Paris*], *141* (*1905*), *No. 18, pp. 686-688*).—It having been claimed that light is necessary for the formation of albuminoids in plants and that the more refrangible rays are most active in this respect, the author investigated the subject and reports experiments carried on during 2 different

seasons to test the effect of blue, black, red, and green colored screens on the production of grain and chaff of wheat.

In 1904 the wheat grown under the black screen was richest in nitrogen, followed by the specimens grown under green, blue, and red screens. In 1905 the experiments were repeated, and in this case the highest amount of nitrogen was found in the plants grown under the green screens, followed by those under the black, blue, and red.

Incidentally the effect of these different colored screens on germination was tested, and out of 100 grains selected, 92 germinated in the check, 94 under the black, 97 under the red, and 99 under the blue and green screens.

Anatomical and physiological changes produced in tropical plants by change of environment, D. BOIS and I. GALLAUD (*Compt. Rend. Acad. Sci.* [*Paris*], *141* (*1905*), *No. 24, pp. 1033-1035*).—Attention is called to the marked physiological and anatomical changes which take place in various economic tropical plants when taken from one region to another, and the failure to secure the successful economic introduction of many plants, such as rubber, fiber plants, etc., is attributed to these changes.

Wound stimuli, parasitism, and gum flow of the Amygdalaceæ, M. W. BEIJERINCK and A. RANT (*Centbl. Bakt.* [*etc.*], *2. Abt.*, *15* (*1905*), *No. 12, pp. 366-375*).—On account of the frequent occurrence of gum flow associated with certain diseases of species of Prunus, the authors have investigated the theories of the effect of wound stimuli to gum flow and the relation of parasites to wound stimuli.

The principal experiments were made with young shoots of the peach and of a reputed hybrid between the peach and almond. The effect of wounding the cambium in both young and old twigs is shown and comparisons are made with the stimulus caused by poisons, heat, etc. The influence of species of fungi in inducing wound stimuli is described, and gum flow is reported as associated with a considerable number of species. In conclusion comparisons are drawn between this form of gum secretion and the resins and gums produced by other plants.

Some experiments in the control of color in plants, H. KRAEMER (*Abs. in Science, n. ser.*, *23* (*1906*), *No. 585, pp. 423, 424*).—In a previous publication (E. S. R., 16, p. 540) the author shows that the unorganized or cell-sap color substances in plants readily react with various chemicals, producing in many instances marked changes in color. It was found that the majority of plant-color substances turned green when under the influence of calcium hydrate, deep red with organic acids, rich purple with potassium and aluminum sulphate, and blue with iron sulphate.

In 1904 the author carried on a series of experiments in this Department for the purpose of determining the effects of certain chemicals on the color principles of plants, the material studied being carnations, roses, and pansies, which were grown in the presence of a large number of chemicals. The results published are considered only preliminary, but it was found that in the case of La France roses the petals became of a uniform pink color when the plants were supplied with iron citrate and citric acid. Maroon roses became dark red when the plants were supplied with phosphoric acid, iron and ammonium sulphate, or sulphuric acid. The maroon roses when treated with sulphuric acid were found to take on a crimson color and they also tended to produce single flowers.

Some factors concerned in color production in a species of Fusarium, J. B. POLLOCK (*Abs. in Science, n. ser.*, *23* (*1906*), *No. 585, pp. 422, 423*).—A series of experiments was carried on with species of Fusarium obtained from the cut ends of corn stubble.

One of the characteristics of the fungus is the bright salmon-pink color which develops on many artificial media under proper conditions. Among the conditions necessary for its development are direct sunlight, in the absence of which only a pale cream color is produced, generally without a tinge of red. Moisture is also an impor-

tant factor in the development of color, and various media were found to influence the color produced by the fungus in a marked degree.

The induction of new species, D. T. MacDougal (*Abs. in Science, n. ser., 23 (1906), No. 585, p. 422*).—The effect of some chemical agents on the development of new species is briefly described in an account of experiments in which the ovaries of Raimannia were stimulated immediately previous to fertilization.

Among the seeds secured were a number which produced plants differing from the normal or typical species, and the series of experiments seems to demonstrate that factors external to the protoplast may exert a profound influence upon the hereditary characters, developing qualities not hitherto exhibited in the parent plants.

FIELD CROPS.

Report of the agriculturist, B. C. Buffum (*Colorado Sta. Rpt. 1901, pp. 20–31, pl. 1*).—A brief report of the work of the agriculturist during the season of 1901 is given. Several varieties of wheat grown for a number of years at altitudes of 7,000 ft. showed a remarkable deterioration when planted at the station. In a field experiment with potatoes, untreated selected clean seed gave the largest yield. The shrinkage of 8 lots of potatoes during 4½ months ranged from 5.2 to 8.5 per cent. Notes are given on a number of varieties of macaroni wheats tested in 1901.

The results obtained with Hanna barley indicated that the variety is well adapted to Colorado conditions. Black oats from Colorado seed gave 71 bu. per acre, North Finnish 60.5 bu., and Silesian 52.4 bu. Three acres of Russian spelt, sown at the rate of 100 lbs. per acre, yielded 181 bu., machine measure. The crop weighed 5,386 lbs., or about 30 lbs. per bushel.

A report of the cooperative grass and forage plants experiments with the U. S. Department of Agriculture at the Colorado Agricultural Experiment Station in 1901, A. H. Danielson (*Colorado Sta. Rpt. 1901, pp. 32–38, pls. 4, dgm. 1*).—The grass garden of the station is described and the species making a good growth, a moderate growth, little growth, or dying out after coming up, and those not germinating are listed and the more important and successful ones briefly noted. The grasses and forage plants under field culture are also briefly discussed.

Succotash as a soiling crop, R. S. Shaw (*Michigan Sta. Bul. 235, pp. 113–127, figs. 4*).—The advantages and disadvantages of several crop mixtures grown for forage from 1903 to 1904, inclusive, are pointed out and notes on their culture and uses are given.

On May 8, 1903, a mixture of 1 pk. of corn, 1 pk. of peas, 1 pk. of oats, and 6 qts. of barley was drilled at the rate of 2½ bu. per acre. The cutting and feeding of this crop to pigs was begun June 24 and lasted 12 days. The yield was at the rate of 22,887 lbs. of green crop per acre. Owing to abundant rainfall, the growth was exceedingly dense and tall. The objection to this mixture was that it did not contain plants making a second growth after cutting.

In 1904 corn, peas, oats, rape, and millet were sown May 7 on two different plats. Pigs were turned in one plat on June 20 and kept there for 32 days. The second growth of rape and millet in this mixture was good.

In 1905 corn, oats, peas, rape, and clover were sown May 1 on one plat and May 20 on another. Floods interfered with the crop, but the data secured from the early sowing showed a yield of green forage of 12.16 tons per acre. Samples taken from 4 representative areas each 2 ft. square showed that these 16 sq. ft. had produced the following number of plants: Oats, 61; peas, 68; rape, 55, and corn 22, their weights being 10.6, 4.2, 2.75, and 0.5 lbs., respectively. The second sowing yielded at the rate of 12.62 tons of green forage per acre and the 4 representative areas, including 16 sq. ft., in this case contained the following number of plants: Corn, 74; peas, 82; oats, 43, and rape 10, the respective weights being 6.9, 1.7, 4.3, and 0.3 lbs. The cutting of this sowing began July 22 and was completed August 11. The composition of samples taken in 1904 and 1905 is recorded.

[Experiments at the agricultural experiment station at Vienna, 1905], O. Reitmair (*Ztschr. Landw. Versuchsw. Oesterr., 9 (1906), No. 3, pp. 148–179*).—The work of the department of agronomy is reviewed and the results secured are briefly reported.

The average results of several fertilizer tests with potatoes, sugar beets, winter rye, and winter wheat show that of the total increase in yield secured from the complete application the following percentages were due to the use of nitrate of soda: Potatoes 48.7, sugar beets 38.2, winter rye 57.5, and winter wheat 40 per cent. The hoed crops received 200 kg. of nitrate per hectare and the cereals 150 kg. These comparatively small applications are regarded in general as the most profitable for the soils under test.

Potash was applied in the form of kainit and potash salt in quantities furnishing 100 kg. of potash per hectare, and the effect of this single application observed for 3 years. The first year the increase in the different crops due to potash was medium and regular, but where kainit was applied to oats no increase was secured. The second year the effect of potash on all crops excepting clover was weak, being weakest with oats. The third year the residual effect was still quite noticeable with clover, where the potash salt showed a better growth than the kainit, while the year before the kainit produced the better crop. The potash requirements of barley did not seem greater than those of other cereals.

Fertilizer experiments on meadows and inoculation experiments with different leguminous plants, together with other work of the station are also reviewed.

Fertilizer experiments on meadows, A. Grete (*Landw. Jahrb. Schweiz, 20 (1906), No. 2, pp. 117–148*).—The results of cooperative experiments carried on from 1898 to 1900, inclusive, are reported. The plats, each containing 100 square meters, were given various combinations of phosphoric acid, potash, nitrogen, and lime at the rate of 0.8, 1, 0.45, and 2 kg. per plat, respectively. Lime was applied only in 1898.

It was found that the soil was very much in need of phosphoric acid while its potash requirement was small, the yields with phosphoric acid alone being almost as large as where the 2 elements were given together. Nitrogen gave a small increase in the yield of dry matter, but the production of protein was smaller than without it. The increase in dry matter was insufficient to pay for its use. Phosphoric acid and potash favored the growth of clovers and proved most profitable, although the potash added comparatively little to the increase in yield.

Some suggestions relative to alfalfa growing in Ohio, C. G. Williams (*Ohio Sta. Circ. 49, pp. 3*).—Brief general directions for alfalfa culture are given.

The station found that on soil derived from sandstone the use of a ton of lime per acre was much more effective than other kinds of treatment, while on a limestone soil the application of lime gave no beneficial results. In some plat experiments on a limestone soil the use of 200 lbs. of steamed bone per acre seemed to have increased the yield over 148 per cent, while an application of 8 tons of stable manure per acre apparently gave an increase of 210 per cent.

Alfalfa seed: Its adulterants, substitutes, and impurities and their detection, H. F. Roberts and G. F. Freeman (*Kansas Sta. Bul. 133, pp. 51–111, figs. 44*).—The impurities commonly occurring in alfalfa seed are enumerated and described, and the results of purity and germination tests made by the station are recorded.

Seed of yellow trefoil (*Medicago lupulina*) was found to be the chief adulterant, but in a number of samples bur clover (*M. denticulata*) and sweet clover (*Melilotus alba*) also occurred. It is pointed out that the seeds of these 3 species, unless present in large quantities, can not be readily distinguished from the seeds of alfalfa. Yellow trefoil and bur clover injure the quality of the forage produced, and on account of their being annuals die out after the first year and thus reduce the stand. Sweet clover is a biennial, and is generally distasteful to stock.

The chief impurity in western alfalfa seed is the dead seed of the alfalfa itself, and the obnoxious weed seeds most commonly present were chiefly those of species of docks and English plantain (*Plantago lanceolata*).

The range of germination in the samples ran from 60 to 96 per cent, with an average of about 83 per cent. The separation of dead alfalfa seed was not found practically possible, and it is recommended that the grading of alfalfa seed be based upon actual germination tests.

Correction of a very unfavorable ratio of lime to magnesia in a soil for the culture of barley, G. Daikuhara (*Bul. Imp. Cent. Agr. Expt. Sta. Japan, 1 (1905), No. 1, pp. 13-16, pl. 1*).—The soil originally contained 0.64 per cent. of calcium oxid and 1.91 per cent of magnesium oxid, representing a ratio of 0.34 : 1. By adding sufficient lime to make the ratio of these two substances 1 : 1 the yield of barley was doubled on well-manured soil, and even more than doubled when the manuring was one-sided or when no application at all was made. This result is attributed not only to the regulation of the ratio of lime to magnesia, but also to the improvement of the physical and chemical condition of the soil resulting from raising the lime content.

Buckwheat, J. L. Stone (*New York Cornell Sta. Bul. 238, pp. 179-193, figs. 5*).—This bulletin gives a general account of the buckwheat plant, with directions for its culture and uses.

An experiment was made by the station in 1901 to determine whether better results could be secured by turning rye under early in the season or by allowing it to grow until shortly before drilling in buckwheat. The results indicated that early plowing and subsequent harrowing to produce a thorough settling of the soil gives the better results. It is recommended that if early plowing is impracticable greater attention should be given to a thorough fitting of the seed bed.

The average yields in a variety test were as follows: Japanese 27.5 bu., Common Gray 26.8 bu., and Silver Hull 19.5 bu. per acre. In cooperative tests by 14 farmers in various parts of the State the average yield of Japanese was 21.29 bu. per acre and that of Silver Hull 20.05 bu.

Buckwheat, E. Haselhoff (*Landw. Vers. Stat., 63 (1906), No. 5-6, pp. 375-406, figs. 11*).—A general description of the buckwheat plant, directions for its culture, a review of experiments conducted with the crop, and a discussion of the chemical composition of the grain, straw, and mill products, together with their feeding value, are given. A bibliography of 17 references is listed.

The cassava industry, L. Colson and L. Chatel (*Culture et industrie du manioc. Paris: A. Challamel, 1906, pp. 95, figs. 7, map 1, dgm. 1*).—This book treats of the culture of cassava on the Island of Réunion, and gives a résumé of the different operations necessary in the manufacture of starch and tapioca. Estimates are given on the cost of production of the crop and the manufactured food materials.

Adulteration of red clover seed, J. Wilson (*U. S. Dept. Agr., Office Sec. Circ. 18, p. 1*).—Of 521 samples of seed of red clover obtained in the open market 116 contained dodder and 5 were found to be adulterated with seed of yellow trefoil. These samples contained from 18.29 to 52.64 per cent of yellow trefoil.

Corn, W. H. Scherffius (*Kentucky Sta. Bul. 122, pp. 155-189, pls. 3*).—A method of selecting seed corn is outlined and a chemical study of the composition of a number of varieties of Kentucky corn is reported. Each variety is described and the results of analyses are given in tables.

These results show that the percentage of nitrogen does not differ materially in the individual whorls of grain on the ear, beginning at the butt, until after the middle is passed, when there is a gradual falling off in the nitrogen content toward the tip. In some instances, however, the grains at the tip contained a higher percentage of nitrogen than the grains in any part of the ear, while in other cases they contained the lowest.

In 3 samples of yellow corn with white-tipped grains scattered about over the ears, possibly due to cross fertilization, there was no material difference in the percentage of nitrogen of the white tipped and the yellow grains. The author concludes that this indicates that there is no change in the nitrogen content from the first year's cross fertilization. Longitudinal rows of grains on opposite sides of the ears gave approximately the same percentage of nitrogen.

Experiments with corn, C. G. WILLIAMS (*Ohio Sta. Circ. 53, pp. 11, dgms. 2*).—The tabulated results of varieties of corn tested for 3 years show that many of them are not adapted to Ohio conditions. Experiments in thick and thin seeding pointed out that the increase in yield was very pronounced up to an average stand of 3.62 plants per hill, the rows being 42 in. apart each way, but that it was accompanied by a decline in average weight per ear, which was especially marked when more than 3 plants were grown per hill.

From field counts made in 63 counties by 328 correspondents it was estimated that the stand of corn in the State for 1905 was 83.6 per cent. The method of conducting an ear-row test plat is described in detail and the total yields of each row of a duplicate test of this kind is shown in a diagram. The yields from the different ears varied from 50 to 115 bu. per acre. Notes are given on a score card for dent corn and on the selection of seed ears.

Cooperative fertilizer experiments with cotton in 1901, 1902, 1903, and 1904, J. F. DUGGAR (*Alabama College Sta. Bul. 131, pp. 17-74*).—In these cooperative experiments the station furnished material and instruction to farmers upon the agreement that the tests be made. The first year 10 reports were received, the second 13, the third 10, and the fourth 21. The conclusions and suggestions are based on these experiments and on earlier work.

The use of acid phosphate was found almost universally beneficial. Kainit, which was less frequently of benefit than acid phosphate, gave its best results where the crop was attacked by black rust. One hundred pounds of this substance per acre was usually found sufficient. The results indicated that on soils containing much clay kainit was unprofitable.

Cotton-seed meal proved to be very effective on all soils except on new land, or on soil rich in vegetable matter. For old lands a mixture of acid phosphate and cotton-seed meal, or of these two substances and kainit, is recommended. A small growth of stalks under favorable conditions of climate and culture is regarded as showing a deficiency of nitrogen in the soil, and a rank growth as indicating that only a small quantity or no nitrogen at all need be applied. The use of phosphates hastened maturity and the freshness of the land reduced the need for nitrogen. After a luxuriant growth of cowpeas or a recent heavy dressing with stable manure or cotton seed, applications of cotton-seed meal were superfluous. Fertilizer formulas for the cotton crop on various kinds of soils in different parts of Alabama are suggested.

The great millet or sorghum in Madras, C. BENSON and C. K. SUBBA RAO (*Dept. Agr. Madras Bul. 55, pp. 122*).—This bulletin gives a popular description of the crop and of the methods of its culture in Madras.

Four-year culture tests with oats, 1901-1904, W. EDLER (*Arb. Deut. Landw. Gesell., 1906, No. 114, pp. 370*).—The individual tests of cooperative experiments for the different years are described and notes are given on the 13 varieties compared. Strube oats gave in general the highest yields of grain, and especially good returns were secured under favorable moisture conditions.

In dry seasons Leutewitz Yellow ranked first in yield of grain, but in seasons with a greater moisture supply several varieties gave better yields. Beseler II succeeded only with a good supply of soil moisture, while Beseler III gave average results for the different years as compared with all the varieties tested. Duppau, Heine Prolific, Heine Trauben, and Anderbeck gave medium yields and were apparently not very readily influenced by weather conditions. Probstei and Fichtelgebirg produced medium yields under unfavorable conditions, but otherwise they were out

ranked in productiveness by a number of sorts. Beseler I gave the lowest yield of grain, but with Strube ranked first in all years in straw production. Anderbeck and Selchow side oats were also heavy yielders of straw, while Selchow Panicle, Fichtelgebirg, Probstei, and Beseler III stood last in this regard.

A high percentage of grain was produced by Selchow Panicle, Beseler III, Duppau, Leutewitz Yellow, Probstei, and Beseler II, and a low percentage by Selchow side oats and Beseler I. Beseler II, Strube, Anderbeck, Probstei, and Duppau produced the heaviest grain, and Heine Trauben, Fichtelgebirg, Selchow side oats, and especially Leutewitz Yellow, the lightest. The liter weight of the grain varied considerably in different years and was quite irregular. Leutewitz Yellow and Beseler III were lowest in percentage of hull and Beseler II, Strube, and Fichtelgebirg highest.

The grain of Beseler I, Selchow side oats, Anderbeck, and Beseler II was richest in protein, while that of Fichtelgebirg and Leutewitz Yellow was poorest. Selchow side oats and Leutewitz Yellow outranked all other varieties in the fat content of the grain, and Leutewitz Yellow also ranked first in ash content. On the average, Fichtelgebirg ripened earliest, but showed the greatest tendency to lodge. Duppau, Strube, and Heine Prolific stood up well, and Selchow Panicle apparently produced the strongest straw. The Beseler varieties, together with Leutewitz Yellow, Heine Trauben, and Strube, proved quite smut-resistant.

The strong stooling varieties were Fichtelgebirg and Leutewitz Yellow, and the weak stooling sorts Strube, the Beseler varieties, Heine Prolific, and Selchow Panicle. The Beseler varieties produced the longest straw, and Fichtelgebirg, Strube, and Leutewitz Yellow the shortest. Anderbeck, the Beseler oats, and Strube were characterized in comparison with the other varieties by thick stems.

A preliminary report on growing Irish potatoes, C. M. CONNER (*Florida Sta. Bul. 82, pp. 387-406, pls. 4*).—A brief discussion of potato culture in Florida is given and the results of experiments in 1905 are tabulated but no conclusions are drawn from the data. The work consisted mainly of fertilizer tests to determine the best sources and the best quantities of the essential plant food elements.

Of different varieties tested Rose No. 4, grown from blossom ends, yielded 215 bu. and grown from stem ends, 225 bu. of marketable potatoes per acre. These were the heaviest yields secured. This same variety grown from Massachusetts seed yielded 160 bu., from Virginia second-crop seed 179 bu., and from seed grown at the station during the previous fall from small potatoes left from the spring crop, 89 bu. per acre.

Some results of potato investigations in 1905, T. C. JOHNSON ([*Quart.*] *Rpt. W. Va. Bd. Agr., 1 (1906), pp. 41-50*).—Potato culture as carried on in West Virginia in the counties bordering on the Ohio River is described with reference to its extent on the bottom lands along the river, the fertilizer applications and crop rotation, the soil and its preparation, planting and cultivating the crop, harvesting and marketing, and the attacks of fungus diseases.

The principal varieties grown are Early Ohio, Carmen No. 1, Carmen No. 2, Green Mountain, and Sir Walter Raleigh. Experiments in spraying with Bordeaux mixture indicated that this was a profitable operation, a marked gain being shown in the production of the highest grade of tubers. With reference to that part of the crop consisting of small tubers spraying was unprofitable.

A rough skin in its relation to the starch content of potatoes, R. KRZYMOWSKI (*Jour. Landw., 54 (1906), No. 1, pp. 57-64*).—Work on this subject by different investigators is reviewed and the author's own results are presented. The rough and smooth skinned tubers of 15 different varieties were analyzed and in 14 cases the rough-skinned tubers were richer in starch. The starch content of the smooth-skinned potatoes ranged from 16 to 19.2 per cent and that of the rough from 17.1 to 21.6 per cent.

On the application of magnesia in the form of magnesium sulphate for the needs of the rice plant, G. DAIKUHARA (*Bul. Imp. Cent. Agr. Expt. Sta. Japan, 1*

(1905), No. 1, pp. 23-29, pl. 1).—The results of pot experiments are reported which "show that in the presence of lime as carbonate the necessary amount of magnesia, when applied as crystallized sulphate for paddy rice in sand culture, is so small that the best ratio CaO : MgO becomes 30:1, while in the form of natural carbonates the best ratio would be 1:1 as Aso [E. S. R., 15, p. 1062] had ascertained. This conclusion will hold good also for various sandy soils, while for clayey soils the best ratio $\frac{\text{CaO as carbonate}}{\text{MgO as sulphate}}$ will differ."

Additional experiments, making comparative tests of sodium nitrate and ammonium sulphate, showed that the application of nitrogen as sodium nitrate was not favorable to rice plants, its relative value as compared with ammoniacal nitrogen being as 40 to 100.

The anatomical structure of the stems of spring rye grown on moor soils and its change under the influence of manurial treatment, P. VAGELER (*Jour. Landw., 54 (1906), No. 1, pp. 1-30*).—The thickness of the stem wall was found to decrease from the base toward the top of the stem. All parts of the stem not protected by the leaf sheaths showed an evenly developed cuticle, but the epithelium was much strengthened in the upper parts of the stem and in the internodes.

At the lower joints of the internodes the stomata under the leaf sheaths remained inactive and there was practically no development of chlorophyll. The hypoderma was found strongest in the lower parts of the stems and in the internodes. The development of the parenchyma was greatest in the lower portions of the stem and in the upper parts of the internodes. The tissue through which protein is translocated prevailed near the head. The proportion of lumina to cell walls in the stem increased from below toward the spike, corresponding to the lesser strength requirements in the upper portions near the head.

The results of experiments to determine the influence of the fertilizer applications used showed that all manurial treatment, excepting the use of phosphoric acid by itself, tended to increase the size of the stem by enlarging the cell lumina at the expense of the cell walls. The parenchymatic tissue also increased with the quantity of fertilizer applied. Potash, without weakening the stem, favored the production of parenchyma and assimilative tissue and a reduction of unproductive tissue. Its use also resulted in a marked strengthening of the cuticle.

Nitrogen remained indifferent toward the length of the stem and the development of the fibro-vascular bundles, but it reduced the quantity of hypoderma, especially in the lower internodes. This result, coupled with a greater production of chlorophyll in the lower parts of the plant and a reduction in percentage of cell wall, weakens the stem. When nitrogen and potash were applied together the effect of weakening the cell wall was quite marked. Phosphoric acid given in excess produced exceptionally low yields. While acting favorably on the development of the framework of the plant, phosphoric acid reduced the total quantity of cell wall, but when applied with potash and nitrogen it had a strengthening effect on the plant.

Experiments with sugar beet, G. CLARKE (*Essex Ed. Com., County Tech. Labs., Chelmsford, 1906, Jan., pp. 22, pl. 1, figs. 3*).—Experiments were conducted at 5 different points. The average yield of sugar beets per acre was 18.3 tons, the percentage of sugar in the beet 16.7, and the purity 84.7. The results with Redtop sugar beet were not included in the average figures just given. This variety gave an average yield of 24.5 tons per acre, with 11.8 per cent of sugar and 79.2 purity.

Seedling canes and manurial experiments at Barbados, 1903-1905, J. P. D'ALBUQUERQUE and J. R. BOVELL (*Imp. Dept. Agr. West Indies, Pamphlet 40, 1906, pp. 119*).—A summary of part of the work with sugar cane carried on under the direction of the Imperial Department of Agriculture is given.

The varieties of canes were grown on black soils in 12 cases and on red soils in 3. Cane B. 208 again gave good results as plant canes, especially on red soils. B. 147

outranked all the other varieties tested on the black soils. Of the newer varieties B. 1,529 stood second on both black and red soils. The results indicated that the application of nitrogen both to plants and rattoons is profitable. Sulphate of potash was also profitable, but phosphatic fertilizers either had no effect or decreased the yield.

Report on experiments with varieties of swedes, 1902–1905, W. ALLAN (*Edinb. and East of Scot. Col. Agr. Bul. 7, pp. 15*).—Twenty-four varieties of swedes were tested for 4 years. The varieties varied in productiveness and quality, productiveness being more inherent in the variety than quality.

The quality of the crop was influenced by the kind of soil, the size of the roots produced, and the variety grown. Wet and cloudy seasons reduced quality more than quantity. The best producing variety was Premier, which gave on an average fully 1½ tons per acre more than Conqueror, which stood next in the tests. In quality Kinaldie stood first, Stirling Castle second, and New Arctic third.

In the production of dry matter per acre Magnum Bonum and Queen ranked first and second, respectively, with an average difference of ½ cwt. per acre in favor of Magnum Bonum. Next to these varieties in the production of feeding material stood Premier, Paragon, and Stirling Castle.

On the lime factor for the tobacco plant, G. DAIKUHARA (*Bul. Imp. Cent. Agr. Expt. Sta. Japan, 1 (1905), No. 1, pp. 17–22, pls. 3*).—In order to determine the best ratio of lime to magnesia in a soil used for the growth of tobacco a series of pot experiments was made in which ratios of 1, 2, and 4 parts of lime to 1 of magnesia were used. The best results were obtained with a ratio of 4 parts of lime to 1 of magnesia. In all cases the tobacco plants were benefited by the application of lime.

The results of seed tests at the German seed control stations (*Mitt. Deut. Landw. Gesell., 21 (1906), No. 11, pp. 121–123*).—The number of samples tested and the average germination and purity at different seed control stations where this kind of work has been in progress for from 10 to 28 years are given in a table and briefly discussed.

Attention is called to the fact that salable beet seed must come up to the following requirements: A kilogram of beet seed must produce at least 70,000 sprouts in 14 days after planting, and of this number at least 46,000 must be produced in the first 6 days. Of 100 seed bolls not less than 75 must have sprouted in this time. The water content of the seed is considered normal up to 15 per cent, inclusive, and up to 17 per cent, inclusive, the seed may still be sold but a deduction in weight for the extra moisture content must be allowed.

Standard seed may contain 3 per cent of foreign matter, but when the content reaches 5 per cent a deduction in weight must be allowed. Over 17 per cent of moisture or more than 5 per cent of foreign matter in a beet sample makes it unmarketable according to the law.

Report of the seed control station at Vienna for 1905, T. VON WEINZIERL (*Ztschr. Landw. Versuchsw. Oesterr., 9 (1906), No. 3, pp. 279–382, pl. 1*).—A review of the work of the station during the 25 years of its existence is given. During this period 200,867 determinations were made.

A list of 83 seed firms cooperating with the station is given, together with a register of the demonstration fields and forage plant and grass seed culture investigations established and in progress since 1898. The work conducted in the Alpine regions from 1890 to 1905 is described and the different investigations carried on in 1905 are noted.

Studies of weeds. I, Some common thistles, J. PERCIVAL (*Jour. Bd. Agr. [London], 12 (1906), No. 12, pp. 705–715, figs. 10*).—The 4 common thistles *Carduus crispus*, *Cnicus lanceolatus*, *C. palustris*, and *C. arvensis* are described and figured and directions for the extermination of each species are given.

HORTICULTURE.

Pineapple culture. III, Fertilizer experiments, H. K. MILLER and A. W. BLAIR (*Florida Sta. Bul. 83, pp. 405–437, pls. 8, dgms. 3*).—This bulletin contains the detailed plan and results of fertilizer experiments with pineapples, extending over a period of 5 years.

The purpose of the experiment was "to find out from what source or sources it is best to obtain fertilizing materials for pineapples; the proper quantity to use for the best results as regards quantity, quality, and shipping properties; best method of applying; ratio of phosphoric acid, nitrogen, and potash; the effect of shading, and to determine any other conditions which will prove of advantage to the industry."

The experiment contained 96 separate plats, with as many variations and combinations of the fertilizers commonly used for this crop. Each plat contained 100 plants and occupied $\frac{1}{130}$ of an acre. All the plats were covered with a lath shed, furnishing $\frac{1}{2}$ shade. Preliminary to the work pineapples were analyzed with reference to the fertilizer constituents contained to determine the proportion in which they exist normally in the plant and fruit. The ratio of the constituents was found to be practically as follows: Phosphoric acid 0.8, nitrogen 1, and potash 2. The results secured on the different sections of the plats are discussed in considerable detail and illustrations given of the plants on many of the different plats.

Acid phosphate was found to have an injurious effect upon pineapples which could be corrected by the use of lime. It is thought that the acid phosphate itself was not the cause of the injury, but rather the sulphate of iron and aluminum which it contained, since acid phosphate derived from bone black did not have any injurious effect on the plants. Since, however, acid phosphate is occasionally colored to represent dissolved bone black, it is recommended that one not experienced in the use of fertilizers should not use any form of acid phosphate whatever for pineapples, but rely upon bone meal or slag.

On the whole the best results have been obtained by the use of about 3,750 lbs. per acre of fertilizer, analyzing 4 per cent available phosphoric acid, 5 per cent nitrogen, and 10 per cent potash, and this formula was perhaps best compounded by the use of bone, blood, and high-grade sulphate.

A number of fruits were analyzed to see if increasing amounts of fertilizer would affect their composition. The results obtained are tabulated, but the data are not considered sufficiently satisfactory to warrant conclusions.

Among the recommendations and conclusions drawn from the whole work, it is shown that as a source of phosphoric acid fine ground steamed bone, bone meal, and slag have given the best results. If acid phosphate is used lime should be added every year or two at the rate of 750 lbs. to the acre. "As sources of nitrogen, dried blood, cotton-seed meal, and castor pomace may be used. Nitrate of soda may be used for the first 6 months and possibly, to a limited extent, for the first year, but after the first year it will probably be safer to eliminate it entirely. Considerable caution is required in its use.

"Of the potash salts used, high and low grade sulphate have given the best results, the latter seeming slightly the better. Muriate has given fair results, though the sulphate undoubtedly gives better results. Kainit should not be used. High-grade tobacco stems, though not used in this experiment, have been used by a number of growers with good results.

"For most of the east coast soils we would recommend 3,500 to 4,000 lbs. to the acre annually of a fertilizer analyzing 4 per cent available phosphoric acid, 5 per cent nitrogen, and 10 per cent potash, to be applied at the rate of four applications a year for the first 18 months, and after this two applications a year; one in February or March, as the conditions may require, and one soon after the removal of the summer crop."

The use of a growing fertilizer on pineapples at the beginning of winter has been found objectionable, since when the plants are started into growth at this time, they are more easily injured by cold weather which may follow in January or February. Ground tobacco stems may be used in the fall, since this material does not cause much growth, but tends to the production, rather, of hardy plants, better able to withstand the cold.

"Within 3 weeks, or as soon as possible after setting out, the plants should have a light application of cotton-seed meal in the bud, about a tablespoonful to the plant. The first regular application should be put on broadcast about 6 weeks later, and be thoroughly worked in with the scuffle hoe." The experiment brought out clearly that when the quantity of fertilizer was increased from a little more than a ton to nearly 2 tons per acre, the number of larger sizes of pineapples was increased to a very profitable extent.

The pineapple crop was injured in 1905 by a frost in February, and some observations were made to determine the relation between the different fertilizers and the frost-resistance of the crop, but no satisfactory conclusions could be drawn.

Pineapple culture. IV, Handling the crop, H. H. HUME (*Florida Sta. Bul. 84, pp. 441–457, pls. 5, fig. 1*).—In the 3 preceding bulletins on this subject, soils, varieties, and results of fertilizer experiments have been considered (E. S. R., 14, p. 459; 15, p. 468; 17, p. 1154). In the present bulletin the author considers the subject of packinghouses and their equipment, field equipment for the harvesting of pineapples, pineapple packages, harvesting, grading, shipping, and marketing fruit with special reference to Florida conditions.

Relative to the picking of pineapples the author states that before reaching full maturity the pineapple is dark, black-green in color and the eyes somewhat pointed and angular. As maturity advances the eyes flatten down somewhat in the center and become slightly elevated around the margins, and the color changes to a very pale green. "The opening and spreading of the crown may be taken as one of the best indications of maturity. . . . As the fruit ripens the stem elongates, the slips grow rapidly and their leaves spread out." In summer fruit intended for short-distance shipments and immediate consumption the basal eyes may be allowed to retain some color. "If considerable time is to elapse between picking and consumption, the fruit should not be quite so mature."

The mango in Hawaii, J. E. HIGGINS (*Hawaii Sta. Bul. 12, pp. 32, pls. 10*).—A popular treatise on the culture of mangoes in Hawaii. In some experiments made to determine the longevity of mango seeds it was found that of seed 31 to 41 days old, 43.5 per cent germinated and produced good plants. These figures indicate that the seed can be preserved much longer than is generally supposed. An analysis is given of the mango, which shows it to contain 82.51 per cent water, 0.39 per cent ash, 0.01 per cent fat, 1.45 per cent fiber, 0.84 per cent protein, and 14.80 per cent carbohydrates.

Directions are given for the manufacture of chutney, marmalade, and jelly from mangoes, and notes are given on mango breeding, diseases and insects affecting mangoes, varieties of mangoes, and mango seedlings in Hawaii.

Vegetable novelties, F. W. RANE and H. F. HALL (*New Hampshire Sta. Bul. 125, pp. 155–180, figs. 27*).—The results are given of tests of some of the more recent varieties of beans, beets, cabbage, carrots, sweet corn, cucumbers, lettuce, watermelons, pumpkins, squash, potatoes, and tomatoes, with brief descriptive notes. Nitro-culture was used without success in the growing of beans and peas.

Horticultural division, G. S. SCOTT (*Orange River Colony Dept. Agr., Ann. Rpt., 1 (1904–5), pp. 169–181*).—Notes on a large number of fruits planted at various government forestry stations, and of the growing of certain vegetables, particularly potatoes, on the same area.

Flower biology and productiveness of fruit trees, EWERT (*Landw. Jahrb.*, 35 (1906), No. 1-2, pp. 259-287, pls. 2).—Results of extensive experiments are given in which the productiveness of apples and pears, as related to the biology of flowers, was investigated. The special point studied was whether there is anything to fear from the standpoint of self-sterility in making large plantings of a single variety. The following conclusions from the author's work, which extended over a period of 3 years, will show the problems on which data were secured:

Numerous seeds and increased size of fruit accompany each other. Seedless fruits occur not only on such seedless varieties as Vaterapfel and Rihas Seedless, but frequently on trees that usually produce fruit with seeds. Seedless fruits grown on the same tree in competition with seeded fruits are smaller than the latter and frequently misshapen. If foreign pollen is withheld from a tree and only seedless fruits produced, these fruits reach the same size as fruits with seeds. In plantings of a single variety the number of seedless fruits and fruits with but few seeds is relatively high. More fruits with than without seeds are found, however, which indicates that even under such difficult conditions, foreign pollen is carried to the blooms in considerable quantities. Waite's division of fruits into self-fertile and self-sterile sorts requires revision, since fruits may be formed in the absence of pollen.

The experiments which have been made to determine the effect of self-pollination on individual branches of a tree are often of negative value because the enclosing of the blooms results in an unfavorable physiological condition and seedless fruits formed on such branches must compete for nourishment with the seeded fruits on other branches.

There is no basis for the fear that large plantings of a single variety in Germany will result in a decreased yield. The ability of pollen to germinate is variable, but may endure for more than 3 weeks.

Fruits and other food products of Jamaica, E. J. WORTLEY (*Jamaica: Gleaner Co., Ltd.*, 1906, pp. 73, pls. 2).—Brief descriptions and notes are given on the more usual fruits and vegetables grown in Jamaica, as well as such subjects as cloves, coffee, kola, vanilla, sugar cane, etc. The plates show the fruits of all the different plants described.

Influence of colored light on the preservation of ripe fruit (*Mark Lane Express*, 94 (1906), No. 3889, p. 399).—In an article abstracted from the *Bulletin of Agricultural Information*, the results of some experiments are given in which it is shown that ripe fruit can be kept for a longer time under blue glass than under ordinary circumstances. In the experiments cited strawberry plants were grown in pots, and when ripe, part of the pots were placed under red glass and part under blue glass. After a couple of days the fruit under the influence of red light was completely spoiled, while those under blue light kept in good condition for 7 days.

Orchard notes, W. M. MUNSON (*Maine Sta. Bul. 128*, pp. 65-80, pls. 4).—Under the above heading notes are given on spraying, insects and diseases affecting apples, winter injuries to apple trees, mice injuries, and suggestions given as to pruning trees and handling fruit.

The injuries to apples following the severe winters of 1903-4 and 1904-5 were thought to be due to the overbearing of the trees following a dry season and the very cold winter. Trees which were well cultivated and fertilized started a vigorous growth near the base of the main limbs from which it will be possible to build a new top. In neglected orchards or where the thrifty trees were left in sod, the injured trees continued to deteriorate and many have died. In order to prevent future winter injury it is suggested that the trees be not allowed to overbear.

If tar paper is used to protect trees from mice injuries, it is considered important that the paper be removed in the spring; otherwise there is danger of the tree scalding. The cost of sufficient wire screen to protect 400 young trees was $7.50. The tar paper for an equal number cost 84 cts. Strips of wood veneer, which cost

$5 per thousand, were also used successfully, but in applying them the work must be done before freezing weather comes or many of them will crack and be useless. A still cheaper form of protection is a coat of paint, providing pure materials are used.

An obscure physiological disease of apple trees, apparently due to the excessive use of nitrogenous fertilizers and the lack of available potash, is briefly described.

The apples of New York, II, S. A. BEACH, N. O. BOOTH, and O. M. TAYLOR (*New York State Sta. Rpt. 1903, pt. 2, pp. IV + 360, pls. 84*).—This volume is similar in make-up to the preceding (E. S. R., 17, p. 559), and is devoted to summer and fall apples which have originated or are grown in New York. It contains an index of the varieties mentioned in the volume, and also a combined index to volumes 1 and 2.

Apple districts of New York with varieties for each, U. P. HEDRICK, N. O. BOOTH, and O. M. TAYLOR (*New York State Sta. Bul. 275, pp. 61, map 1*).—An alphabetical catalogue is given of the apples that have grown or have originated in New York, in which the characteristics and season of each variety are noted, its suitability for different sections of the State pointed out, and general remarks given on its usefulness.

In addition a discussion is given of the distribution of varieties of apples and the adaptation of groups of apples. Under the latter heading a large number of varieties of apples have been classified into groups, such as Aport Group, Baldwin Group, Early Harvest Group, Fameuse Group, etc. New York State is divided into 9 pomological districts, and lists of varieties which may be successfully cultivated for different purposes given for each. A list of varieties of apples which are unworthy a place among the apples of New York is included in the bulletin, as well as a list of those which have not been sufficiently tested to justify comment on them.

Peach and plum culture, A. B. MCKAY (*Mississippi Sta. Bul. 93, pp. 16, figs. 3*).—An account of the laying out, planting, and yields of a 9-acre peach orchard, 6 acres of which was planted for commercial purposes with 900 Elberta and 50 Triumph peach trees, and the remaining 3 to numerous varieties of peaches and plums.

The orchard was planted during the first days of January, 1898. In 1899 the trees were severely frozen, so that the bark from the ground to the crotches of the lower branches could be easily pulled away from the tree. They were severely headed back and entirely recovered.

Three crops of peaches have been secured from the commercial orchard. The yield in 1901 was 550 bu.; 1902, 520 bu.; and in 1904, 1,575 bu. The total net returns from the shipment of these fruits to St. Louis, Chicago, and St. Paul were $2,500. The first year the orchard was set out sweet potatoes were grown between the rows, and yielded at the rate of 100 bu. to the acre. The next season peas were planted between the rows, and yielded at the rate of 20 bu. per acre. The total receipts from these crops amounted to $390. The cost of the trees and the expense of preparing the land and planting was $66.75. The care of the orchard is placed at $270, making a total expense of $336.75.

There was, therefore, a profit on the crops grown in the orchard of $53.25, which may be regarded as a good rental value on the land for 3 years, at the end of which time the orchard was ready for fruit-bearing, free from encumbrances. For the next 4 years the average returns from the orchard and fruit were $625, or $104.16 per acre. The annual expense of caring for the orchard during this period is placed at $30, leaving a clear gain of $74.16 for each acre during the 4 years.

Brief descriptions are given of 20 varieties of peaches, and of 7 varieties of plums grown in the experimental orchard. Relative to the fruit produced on different kinds of soil, the author states that trees on the stiff, heavy clay over a light-colored, sticky and poorly drained subsoil made a rather unhealthy growth, a large percentage of the trees died, and the fruit lacked color and flavor. "On the deep, strong clay loam

over an orange-colored clay subsoil the trees have grown rather too vigorously." It has been difficult to keep wood growth within proper limits, but "rather more fruit has set on these trees than in other parts of the orchard."

On light, grayish-colored soil the trees are medium sized, require but little pruning, and produce a fair amount of fruit of good quality, but show signs of nearing the end of their period of usefulness. On red clay over deeper red subsoil "the trees are of medium size, but healthy, well shaped, and require but little pruning. The fruit on this section is invariably more highly colored, freer from defects, more uniform in size and shape, and more highly flavored than that from other parts of the orchard."

Peaches for home and market, W. J. GREEN and F. H. BALLOU (*Ohio Sta. Bul. 170, pp. 157–186, figs. 35*).—Popular directions are given for the culture of peaches, including recommendations as to the soil and its preparation, location, trees, planting, cultivation, fruit thinning, etc., with brief descriptions of 30 of the better sorts.

Varieties of strawberries and cultural directions, O. M. TAYLOR (*New York State Sta. Bul. 276, pp. 63–79*).—The author describes 27 of the standard and newer varieties of strawberries which have been grown at the station, and gives brief cultural directions for strawberries.

In 1905 the season was specially favorable at the station for a good strawberry crop. Fairfield and Weston No. 1 were among the earliest of the desirable kinds. Weston No. 1 produced large fruit of desirable size to the close of the season, but Fairfield appeared to be valuable only on account of its earliness. Among the latest sorts were Cardinal, Mark Hanna, Mead, President, Ridgeway, and Rough Rider. All of these, except Cardinal, produced large fruit of desirable size to the close of the season. The author suggests that the varieties Joe and Mead should be planted closer than other varieties. Mark Hanna was the most productive, though low in quality. President was of largest size and an excellent show berry, but deficient in quality. Mark Hanna yielded at the rate of 12,400 qts. per acre, while Midnight, the least productive variety, produced but 1,114 qts. per acre.

Strawberries, O. M. TAYLOR (*New York State Sta. Bul. 276, popular ed., pp. 8*).—A popular summary of the bulletin noted above.

Marketing strawberries (*Country Gent., 71 (1906), No. 2780, pp. 450, 451*).—An account of a successful cooperative society for marketing strawberries, located at Neosho, Mo., with some details as to methods of marketing and doing business.

Longevity of grapes of various varieties and species in north Texas, T. V. MUNSON (*Texas Farm and Ranch, 25 (1906), No. 7, p. 5*).—The author gives the results of growing 69 varieties and species of grapes for 19 years in Texas, on a light sandy soil from 6 in. to 3 ft. deep and resting on red and yellow clay subsoil. The data are largely given in tabular form. They show the names of each variety, its specific blood, the number of vines of each variety planted 19 years before, number and percentage of vines now alive, degree of profitableness, diseases affecting and present condition of each variety.

The author considers the native Post grape (*Vitis lincecumii*) the most valuable of all American species in many respects. It therefore has been used extensively in hybridizing. The article refutes the statement of H. M. Stringfellow to the effect that the Aestivalis types of grapes are the most reliable in the interior of Texas. The tabular data given show a number of varieties superior to these.

Varieties and species of cultivated cacao, M. A. FAUCHÈRE (*Jour. Agr. Trop., 6 (1906), No. 57, pp. 76–79*).—Brief descriptions of varieties and species of cacao, with an account of their respective uses.

Second report on pecan culture, H. H. HUME (*Florida Sta. Bul. 85, pp. 463–501, pls. 8, figs. 14*).—This is a popular bulletin on the pecan, dealing with its botany and culture in Florida. Such matters as propagation, grafting, nursery growing, topworking, preparation of soils, the planting of the orchard, cultivation, fertilizers to use, methods of pruning, harvesting, marketing, and varieties, are considered in

detail. It is similar in character to the two previous bulletins issued on this same subject (E. S. R., 11, p. 57; 12, p. 559).

Relative to budding the author states that the buds now commonly used are those which have been formed just previous to the time of budding. The recommendations of Oliver (E. S. R., 14, p. 968) that dormant buds of last season be used, has not met with favor in Florida because of the large amount of wood which must be sacrificed to secure a few buds. The best trees for planting in the pecan orchard are well grown 1-year-old trees, from 3 to 5 ft. high. The best time to plant is in the latter part of November to the first of February. The 10 varieties which the author believes worthy of cultivation in Florida are described and notes given on their origin.

All the spireas worth growing, J. DUNBAR (*Gard. Mag.* [*N. Y.*], *3* (*1906*), *No. 4, pp. 206–210, figs. 8*).—Of the 50 species of spireas in cultivation in the United States only 14, in the author's opinion, are worth cultivating, and these belong to two great natural groups, the early bloomers, which are white flowered, and the late bloomers, which are some shade of pink, with two exceptions.

The first group is pruned in June; the second in winter. These 14 species are divided into 5 flowering types, each of which is illustrated. The culture of spireas is given, with descriptions of each species of importance. A systematic key or guide is given to the horticultural value of these species.

The American carnation, A. HEMSLEY (*Gard. Chron., 3. ser., 39* (*1906*), *No. 1002, pp. 145, 146*).—The author states that the introduction of the variety Mrs. T. W. Lawson in England has led to the extensive cultivation of American carnations in England, and that the American varieties are far in advance of the English. A number of varieties are described and methods of cultivation discussed.

Further experiments on inheritance in sweet peas and stocks, W. BATESON, E. R. SAUNDERS, and P. C. PUNNETT (*Proc. Roy. Soc.* [*London*], *Ser. B, 77* (*1906*), *No. B 517, pp. 236–238*).—Some of the peculiarities in color inheritance among sweet peas and stocks are pointed out as the result of experimental investigation.

FORESTRY.

The forestry work of the Ohio Experiment Station, W. J. GREEN and C. W. WAID (*Ohio Sta. Circ. 50, pp. 11, figs. 5*).—A considerable amount of cooperative forestry work with farmers is being undertaken. In all 355 plats have been planted to forest trees in different parts of the State under the supervision of the station.

The plan is to give aid to those who wish to help themselves rather than to carry on large forestry operations independently. Some forestry work is being done at the station. In all about 9 acres have been planted to *Catalpa speciosa*, black or yellow locust, Osage orange, white ash, green ash, larch, black walnut, and mulberry. Seedling trees are furnished by the station to farmers without cost.

It is stated that in a catalpa grove 23 years old, the timber value was $326, or $14.17 per acre for each year since planting. In the case of the locust grove 19 years old, the value was $341.76, or $17.98 per acre for each year since planting.

Forest planting in the sand-hill region of Nebraska, G. PINCHOT (*U. S. Dept. Agr., Forest Serv. Circ. 37, pp. 5*).—The results of experiments in growing pine trees on the sand hills of Nebraska seem to indicate that western yellow and jack pine can be successfully used in this region.

The best of the jack pine trees set out on the Bruner plantation in 1890 are now 18 to 30 ft. high. The western yellow pine (bull pine) although not as fast growing as jack pine, is longer lived and is a more valuable tree when matured, and is equally well adapted to the region for planting. Suggestions are given on where to secure planting material and methods of planting. The cost of wild jack pine seedlings is placed at $5 per thousand delivered, and of yellow pine $6 to $15 per thousand. The cost for material and labor is placed at $2.30 per acre.

Review of forest administration in British India, S. EARDLEY-WILMOT (*Rev. Forest Admin. Brit. India, 1903-4, pp. 63, maps 2*).—In addition to the usual data regarding forestry affairs in 1903-4, a 5-year review is given of forestry conditions in India, in which it is shown that the forest area has increased from 81,869 square miles in 1899 to 96,466 square miles in 1904. The working plans at the end of 1904 covered 33,680 square miles. The total cubic feet of timber and fuel cut during this period was 236,016,000. At the same time 214,505,000 bamboos were cut, and the minor forest products amounted to 4,756,000 rupees. The total revenue for the 5-year period was 19,658,000 rupees; the total expenses, 11,269,000 rupees.

Relative to the Imperial Forest School, it is shown that, since its establishment in 1899, 673 students have gone out of the school, of whom 418 are now in government service, 135 in that of native states, etc. The average cost of education per head is 2,606 rupees, without taking into consideration the cost of the buildings.

The appendixes contain the usual data in regard to the forest survey operations, expenditures, receipts, etc. Two large maps of India are given, one showing the distribution of forest lands in India, and the other the forest survey working plans now in operation.

How shall forests be taxed? A. GASKILL (*Forestry and Irrig., 12 (1906), Nos. 3, pp. 119-122; 4, pp. 172-177*).—A paper read before the Society of American Foresters, in which inequitable taxation is held responsible for much of the present forest destruction. Suggestions are given as to the principles which should be applied in the taxation of forests. European systems of taxation are briefly noted.

The author holds that forests should be assessed apart from the land on which they stand, and since they are of public benefit the commonwealth should bear a part of the cost of maintaining them—that is, the State should be made to contribute its share of the cost, as well as the counties in which the forests are located. The greater part of the tax on the forest should fall due when the timber is sold, and the deferred tax should bear a fair relation to the net yield of the property. The owner is entitled to a fair annual return on his investment.

In the enactment of future tax laws relative to forest property, three considerations should enter. "(a) Necessity—the support of the local government; (b) equity—an assessment based upon the actual yield, collection of the tax (on the trees, not on the land) deferred until the crop is sold, and a recognition of the peculiar risks—fire, trespass, etc.—to which forests are subject; (c) encouragement—a special rating of the property to compensate the owner for whatever expense attaches to maintaining the forest in a condition that best serves the public interest."

Kealia forest reserve (*Hawaii. Forester and Agr., 3 (1906), No. 2, pp. 61-68*).—This proposed forest reserve contains 9,935 acres. Its purpose is to protect the natural forest covering the watershed of the northern end of the Puna District of Kauai. A description is given by the superintendent of forestry, R. S. Hosmer, of the lands and forests included.

Ewa forest reserve (*Hawaii. Forester and Agr., 3 (1906), No. 2, pp. 68-79*).—Recommendations, with resolutions relating to the establishment of Ewa forest reserve, are given, with a report by the superintendent of forestry on the area of land included, and an account of the forest. The purpose of the reserve is to insure the continuance of the forest on the Koolau Mountains, and to increase its efficiency as a protection forest by bringing the area under a system of forest administration. The total area of the whole reservation is approximately 28,550 acres.

The black wattle in Hawaii, J. G. SMITH (*Hawaii Sta. Bul. 11, pp. 16, pls. 3*).—The results are given of harvesting a 6-acre grove of Australian black wattle (*Acacia decurrens*) about 13 years old, and directions given for the cultivation and harvesting of this tree in Hawaii. Some data are also given on the influence of climate on the tannin content of black wattle, the production of tan-bark extracts, details of

tanning processes, and suggestions on what to do with the wood. The insect enemies of black wattle in Hawaii are briefly enumerated by D. L. Van Dine.

The wattle appears to thrive best in Hawaii on rather heavy soils at an elevation of 800 to 3,000 ft., where the rainfall ranges from 80 to 150 in. per annum. The 6-acre tract harvested grew on a steep slope at an elevation of 600 to 800 ft. It yielded 38 tons of bark. The 36 tons which were sold brought $839.44, and in addition 500 fence posts and 88 cords of firewood were secured. The firewood was sold for $689.25, making the total value of the tract a little over $1,600. The trees at this time had reached their full development and during the preceding 4 years about 20 per cent of them had died, some because they had reached their limit of growth, and others on account of injury from stock and insects.

Under methods of cultivation, it is stated that 1 lb. of seed will plant 10 acres. Before planting, the seed should be either covered with boiling water and allowed to stand 24 hours, or scorched in hot ashes to soften the hard outside skin to facilitate germination. It is considered more economical to plant the seed in place than to sow in nursery rows and transplant. The trees on good soil should be ready to cut in 10 years. In the station grove trees of the same age varied from 18 in. at the butt, when growing on rich soil with heavy rainfall, to only 6 in. in diameter on rocky thin soil at a lower and drier elevation. Ten-year-old trees should yield at least 100 lbs. of green bark, equal to 50 lbs. of dry bark. It is considered doubtful whether black wattle can be profitably cultivated except on land of fairly good character.

The best bark was obtained by drying under roofs. The main point seems to be to dry in such a manner that the bark will not mold. Where sufficiently large areas are to be harvested, the author believes it would pay to build a large drying house carrying temporary slatted floors 18 in. apart, on which the green bark, cut into lengths of 2 or 3 in., could be uniformly distributed for drying.

In investigating the influence of climate on the tannin content it was found that in the case of koa bark (*Acacia koa*), that taken from trees above Hilo showed 17 per cent tannin, while samples taken from a much drier district showed only 12 per cent. Samples of wattle bark taken from trees growing in a very wet district showed fully as high tannin content as trees growing in a very dry district. The range of tannin in this bark varied from 25 to 36 per cent. No apparent relation was found between the tannin content and the soil or season. The highest yield, therefore, of tannin per acre can be secured from lands on which the trees during the normal growth will produce the largest amount of bark, and this is likely to be obtained where the rainfall is sufficiently heavy to afford the trees uninterrupted growth.

The wood is stated to be hard and tough, and comparable with algeroba in fuel value, but somewhat more difficult to split. It checks in drying. Some suggestions are given on its use in making wood alcohol. It is estimated that 200 acres of ground planted to black wattle would yield 500,000 cu. ft. of wood in 10 years. By distillation this would give a minimum of 1,650 tons of charcoal, 15,000 gal. of wood spirits, 380 tons of acetate of lime, and a large amount of wood tar and creosote, having a total value of $44,000, while the cost of production should not exceed $20,000.

How to prune young locust and catalpa trees, W. J. Green and C. W. Waid (*Ohio Sta. Circ. 51, pp. 6, figs. 3*).—Locust trees are nearly self-pruning. They have a tendency to produce one fork and if this is removed, no attention need be paid to the smaller limbs. With the catalpa the authors recommend the cutting off of the tree to the level of the ground when 2 or 3 years old and allowing but one sprout to develop from the stump. If the trees have made a good root growth, they may be cut back the second year, but if not, pruning should be deferred until the third year. Late winter or early spring is considered the best time for cutting back.

Northern limit of the papaw tree, C. A. WHITE (*Science, n. ser., 23 (1906), No. 593, pp. 749–751*).—A discussion of the distribution in the United States of the papaw (*Asimina triloba*), persimmon, and pecan.

Packing seeds for the Tropics, J. H. HART (*Gard. Chron., 3. ser., 39 (1906), No. 1010, pp. 275, 276*).—The author calls attention to the necessity of packing seeds intended for the Tropics in dry air and in tinfoil packets in order to preserve their ability to germinate. He cites an instance in which English peas imported into Trinidad in ordinary packets gave a 95 per cent germination when first sown. The sowing a month later gave 75 per cent. At the third sowing, 30 days later, the percentage of germination was 40, and at the fourth sowing the percentage of germination was but 20.

Suitability of New South Wales timbers for railway construction (*Indian Forester, 32 (1906), No. 2, pp. 74–77*).—This is a review of the report of the forestry branch of New South Wales for 1904–5.

It appears that the timber area of commercial value in New South Wales is about 20,000,000 acres, or 10 per cent of the area of the State. Up to 1904 about 7,503,200 acres of the forest area had been examined and reserved from sale. The value of the timber exported has risen from $225,145 in 1895 to $794,230 in 1904. Ironbark is used largely for piles, trams, girders, and transoms of bridges because of its strength and durability. Tallowwood, gray and red gum, blackbutt, and Sydney blue gum for decking and light scantling, and turpentine and ironbark for jetty and pier work.

Under favorable conditions ironbark has lasted 40 years as bridge timber, and turpentine piles have been found perfectly sound after standing 40 years in salt water. It is stated that Australian hardwoods last much longer in the track than the timbers commonly used in Europe and North America.

Report on the turpentine industry in the United States, BELL (*Diplo. and Cons. Rpts. [London], Misc. Ser., No. 647, pp. 17*).—A report on the turpentine industry in the United States by the British commercial agent, the data for which are largely based on the reports of the U. S. Department of Agriculture.

DISEASES OF PLANTS.

Notes on miscellaneous diseases, K. MALKOFF (*Ghodishen Otchet Drzhavnata Zeml. Opitna Stantziya Sadovo, 2 (1904), pp. 156–233 [German Summary], pp. 19–22, pls. 3*).—Notes are given on a number of diseases and insect injuries of economic plants.

Among the subjects treated are the spot disease of chick-peas due to *Ascochyta pisi*, which the author says may be controlled with Bordeaux mixture; the control of plum pockets with 3 per cent Bordeaux mixture; combating rose rust with Bordeaux mixture; the brown rot of plums (*Monilia fructigena*); a bacterial disease of mulberries; the use of Paris green, tobacco extracts, etc., against insects; and critical notes on plant diseases observed in Bulgaria in 1904.

Laboratory notes, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt., 13 (1905), pp. 405–428, pls. 19, figs. 5*).—Brief descriptive notes are given on a number of diseases of plants. Among them are a disease of Swedish turnips (*Phoma napo-brassicæ*), apple and pear canker (*Nectria ditissima*), apricot coral spot (*N. cinnabarina*), onion mildew (*Peronospora schleideni*), bean anthracnose (*Colletotrichum lindemuthianum*), broad bean rust (*Uromyces fabæ*), hollyhock rust (*Puccinia malvacearum*), a number of diseases of roses, club root of cabbage (*Plasmodiophora brassicæ*), etc.

Contribution to the life history of some Uredineæ, E. FISCHER (*Centbl. Bakt. [etc.], 2. Abt., 15 (1905), No. 7–8, pp. 227–232*).—Notes are given on *Pucciniastrum padi* and *Puccinia liliacearum*.

Investigations on the stinking smut of wheat and its control, K. MALKOFF (*Ghodishen Otchet Drzhavnata Zeml. Opitna Stantziya Sadovo, 2 (1904), pp. 139–149,*

[*German Summary*], *pp. 12-14*).—The author investigated the effect of time of seeding on smut production, seed treatment with fungicides, and varietal resistance. No striking differences could be noted in the amount of smut that could be attributed to the time of seeding.

In the experiments for seed treatment the effect of hot and cold ashes, dry air, cold water and milk of lime, Bordeaux mixture, hot water, copper sulphate solutions, formalin, and corrosive sublimate solutions were tested. All the treatments reported diminished the germinative ability of the wheat to some extent, the least injury reported being with the lots of seed treated with 0.1 per cent formalin, followed closely by the lot soaked for 5 minutes in Bordeaux mixture. The seed of the different lots was sown and counts made of all smutted stalks and heads.

Practically all smut was prevented by the treatments with Bordeaux mixture, formalin, and 0.5 per cent copper sulphate solution, each treatment being about the same in efficiency. Mixing the grain with dry ashes immediately after thrashing was next in efficiency, only 3.5 per cent of the plants and 2.5 per cent of the heads being smutted.

Marked differences in varietal susceptibility are noted.

Investigations on the mosaic disease of tobacco, F. W. T. HUNGER (*Ztschr. Pflanzenkrank., 15* (*1905*), *No. 5, pp. 257-311, fig. 1*).—A review is given of the various theories regarding the cause of the mosaic disease, particular attention being given the bacterial theories of Mayer, Iwanowski (E. S. R., 13, p. 361), and Prillieux and Delacroix (E. S. R., 5, p. 1019), and the theories of Beijerinck (E. S. R., 10, p. 1058), and Woods (E. S. R., 13, p. 146; 14, p. 264), after which the author states and elaborates his theory regarding the causes of this disease.

According to the author's view any disturbances in the normal metabolism of the plant may result in the variegation characteristic of the mosaic disease. He holds that the immediate cause of the disease is an unorganized ferment of the toxophore group of Oppenheimer rather than oxidizing enzyms, as proposed by Woods and others. The mosaic disease must not be confused with variegation as it occurs in ornamental plants, which has been shown to be a not infrequent phenomenon in certain species of Nicotiana. It is also said to differ from the disease described by Sturgis under the name "calico" (E. S. R., 11, p. 755).

Some of the factors favoring the mosaic disease are described and the results of investigations on meteorological conditions and soils in Java are given. A bibliography of literature relating to this subject completes the article.

Combating the mosaic disease of tobacco, H. JENSEN (*Centbl. Bakt.* [*etc.*], *2. Abt., 15* (*1905*), *No. 13-14, pp. 440-445*).—In commenting upon the possibility of combating the mosaic disease through breeding experiments, the author briefly describes an experiment which he thinks shows the impossibility of producing resistant races within a single year, as has been claimed by others.

The author believes it will be possible to develop resistant varieties, but that it will be found best to work with resistant races within varieties of known quality, rather than attempt to develop new types whose chief recommendation is hardiness or resistance.

Potato diseases, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt., 13* (*1905*), *pp. 346-363, pls. 6, figs. 2*).—A brief account is given of spraying experiments which successfully reduced the percentage of loss due to various potato diseases, and descriptions are given of the following diseases of potatoes: Late blight (*Phytophthora infestans*), early blight or leaf curl (*Macrosporium solani*), bacteriosis (*Bacillus solanacearum*), scab (*Oospora scabies*), dry rot (*Fusarium oxysporum*), a wet rot which is believed to be of bacterial origin, and brown spot, which is of an uncertain cause. Where known, suggestions are offered of means for preventing these diseases.

Note on the facultative saprophytism of Alternaria solani, A. H. COCKAYNE (*New Zeal. Dept. Agr. Ann. Rpt., 13* (*1905*), *pp. 428-430*).—A report is given of a

series of experiments with *Alternaria solani* to determine whether it has lost its power of developing saprophytically.

Healthy leaves and leaves infected with *Phytophthora infestans* were inoculated with conidia of *A. solani*, and after developing, the spores were gathered and sown on leaves attacked by the late blight. These infections were repeated for six generations, when the conidia were sown on healthy leaves and kept in a damp chamber. The conidia germinated freely, but the mycelium was poorly developed and no spotting of the leaves resulted, the mycelium appearing to live almost entirely on the surface of the leaves.

It appears that through a space of six generations this fungus, which has become parasitic, was so reduced through gradual adaptation as to be converted into an obligate saprophyte.

Heart rot of beets, mangels, and Swedish turnips (*Jour. Bd. Agr.* [*London*], *12* (*1906*), *No. 10, pp. 596–598, fig. 1*).—A description is given of a disease, attributed to the fungus *Sphærella tabifica*, which is said to be not uncommon in France, where it causes considerable damage to sugar beets. In England the fungus has recently made its appearance, being particularly destructive to mangels and Swedish turnips.

The disease rarely appears before the middle of August, and first attacks the stalks of the largest leaves. Its presence is indicated by the wilting of the leaves, such as follows a hot, dry day; during the night the diseased leaves do not recover, but remain lying on the ground, turn yellow, and decay. Later in the season, when the leaf stalks are dead and dry, a second form of fungus fruit appears on the bleached patches, and some time later the mycelium of the fungus passes into the crown of the root, gradually extending downward. Finally the entire root is reduced to a blackish decayed mass.

The fungus seems to be able to pass the winter in diseased roots left in the field, and where the disease appears, it is recommended that the crop should be harvested immediately and all diseased leaves and roots gathered and burned or deeply buried.

Yellow varieties of mangels appear to be more susceptible to disease than others, as shown by infection experiments.

The drop disease of cabbage, J. RITZEMA BOS (*Tijdschr. Plantenziekten, 11* (*1905*), *pp. 105–117, pls. 3*).—A description is given of a disease of cabbage said to be due to *Phoma oleracea*. It has appeared in some of the most important cabbage growing districts of Holland and is proving quite destructive.

Three fungus diseases of the cultivated ginseng, H. S. REED (*Missouri Sta. Bul. 69, pp. 43–66, figs. 9*).—According to the author, ginseng plantations have increased in number and extent so that ginseng now constitutes an important crop in the State.

The first occurrence of disease on ginseng plants was reported in 1904. At that time the disease seemed to be due to a leaf-spot fungus, and it was thought that spraying with Bordeaux mixture might keep it in check. Later investigations showed that a number of diseases were present and they were not similar to those described from New York (E. S. R., 16, p. 271). On this account the author made a detailed study of the diseases and the fungi causing them. The diseases described are stem anthracnose, leaf anthracnose, and wilt.

The stem anthracnose is due to the fungus *Vermicularia dematium*, and it makes its appearance about 30 days after the plants appear above the ground, producing numerous black scars on the stems of the plants. The stalks are frequently so badly attacked that they break off before the upper portions become wilted. The direct injury is due to the filaments penetrating the cortical and sclerenchyma layers, disintegrating them, and later breaking through the epidermis and forming black spore-producing bodies This disease can be readily checked by the use of Bordeaux mixture.

The leaf anthracnose, caused by *Pestalozzia funerea*, made its appearance early in July, when black, velvety patches were observed at the bases of the leaves and flower stalks causing them to die and fall off. This form of anthracnose caused the death of thousands of young plants, and it was found that it also could be kept in check by spraying with Bordeaux mixture.

The wilt disease described is due to *Neocosmospora vasinfecta*, and this trouble has proved a very serious one, whole plantations often being destroyed in a single week. As the name suggests, the disease is to be recognized by the wilted appearance of the plants, and in this respect it greatly resembles the wilt of cotton, watermelon, and cowpeas. In fact, the fungus is considered identical with that causing the wilt of those plants.

The author investigated the entrance of the fungus through the roots, but a careful examination failed to show any signs of fungus infection. There was evidence, however, for believing that the fungus enters the plant at the base of the stem through the lesions caused by the stem anthracnose. This is shown from the facts that careful microscopical examination failed to reveal the presence of any fungi in the young parts of the roots, that where as a result of spraying there was no anthracnose fungus the plants were not affected by the wilt, and that the wilt disease never appeared until about 2 months after the stem anthracnose had made its appearance.

The fungus is not found except in the fibrovascular bundles while the plant is alive, while it is very customary to find the spore balls in the interior of dead, hollow stems, etc. The observations of the author have led to the conclusion that the wilt disease can be controlled by keeping the plants free from anthracnose and other fungi which produce lesions on the stems.

A technical account is given of the diseases and of the fungi causing them.

A Phytophthora rot of apples, etc., A. OSTERWALDER (*Centbl. Bakt.* [*etc.*], *2. Abt.*, *15* (*1905*), *No. 13–14*, *pp. 435, 440*).—Following a severe rain and hailstorm in June, 1904, apples were found affected with an unusual rot. Upon investigation the cause was determined to be *Phytophthora omnivora*, and inoculation experiments showed the possibility of its causing the rotting of apples and pears within a relatively short time.

Notes on the so-called closed canker of apple trees, K. VON TUBEUF (*Naturw. Ztschr. Land u. Forstw.*, *3* (*1905*), *No. 2*, *pp. 92–94*, *figs. 2*).—The author describes an unusual form of apple-tree canker, in which the fungus stimulates the tree into the production of large knotty outgrowths. When sawed through, the perethecia of *Nectria ditissima* were found inside the knots.

A bacterial disease of cherry trees, R. ADERHOLD and W. RUHLAND (*Centbl. Bakt.* [*etc.*], *2. Abt.*, *15* (*1905*), *No. 12*, *pp. 376, 377*).—A preliminary note is given on a bacterial disease of cherry trees that has been quite destructive in some of the Rhine provinces of Germany.

This disease appears to have been hitherto confused with that described as due to the fungus *Valsa leucostoma* (E. S. R., 15, p. 270), but it lacks the characteristic outgrowths of that disease. The organism has been isolated and cultivated, and inoculation experiments show that it is capable of causing the trouble. The bacterium is described by the authors as *Bacillus spongiosus*. The disease is believed to be widely distributed throughout Germany. The authors intend further studies upon it, and suggest that it may also attack other stone and pomaceous fruit trees, as similar appearances have already been noticed on plum and apple trees in the vicinity of Dammkrug.

Observations on the biology of the olive-tubercle organism, E. F. SMITH (*Centbl. Bakt.* [*etc.*], *2. Abt.*, *15* (*1905*), *No. 7–8*, *pp. 198–200*, *pl. 1*).—The author was led to investigate the organism causing the olive knot (*Bacillus oleæ*), to confirm statements by Schiff (E. S. R., 16, p. 987) relating to the biology of the bacillus.

The organism was isolated from olive knots from California, and studied under various conditions, comparisons being made with organisms plated out from material received from two different sources in Italy. In all of the material examined there

were found to be in addition to *B. oleæ* a number of other organisms. Successful inoculation experiments were made with the organisms from California and Italy.

The author failed to find resemblances between his bacteria and that described by Schiff, and he concludes that no olive knots can be produced with pure cultures of the spore-bearing organisms described by Schiff.

Investigations on olive tuberculosis, R. SCHIFF (*Centbl. Bakt.* [*etc.*], *2. Abt., 15* (*1905*), *No. 7–8, pp. 200–211*).—The results of the author's investigations on the cause of the olive tuberculosis and studies on the biology of the organism are given, a preliminary account of which has been noted elsewhere (E. S. R., 16, p. 987).

The occurrence and prevention of gooseberry mildew, R. EWERT (*Naturw. Ztschr. Land u. Forstw., 3* (*1905*), *No. 5, pp. 200–204*).—Attention is called to the occurrence of *Glœosporium ribis* on gooseberries, the fungus causing serious injury to the plants.

An experiment in preventing the mildew was carried on in which the shrubs were sprayed with ordinary Bordeaux mixture, milk of lime, iron-free Bordeaux mixture, Bordeaux mixture to which varying proportions of iron sulphate were added, and soda Bordeaux. The shrubs were sprayed twice during the season, and the effect as shown on the bushes is described. The author recommends in general the spraying of the shrubs with a 1 per cent solution of ordinary Bordeaux mixture. He also recommends that resistant varieties, as far as possible, be planted, and that they be stimulated to rapid growth by means of cultivation and the use of fertilizers.

The American mildew of gooseberries, J. RITZEMA BOS (*Tijdschr. Plantenziekten, 11* (*1905*), *pp. 170–176*).—Notes are given on the gooseberry mildew (*Sphærotheca mors-uvæ*), which has recently appeared in a number of places in Europe, where it seems to be very destructive. The fungus and its effect on the host are described, and suggestions given for its prevention.

Further investigations on the bacterial disease of sesame, K. MALKOFF (*Ghodĭshen Otchet Drzhavnata Zeml. Opītna Stantzīya Sadovo, 2* (*1904*), *pp. 149–156,* [*German Summary*], *pp. 14–19, pls. 5*).—In continuation of a previous note (E. S. R., 16, p. 65) the author gives additional accounts of the biology of the organism causing the wilt of sesame.

The disease is still poorly known but may be recognized by the stems of badly infested plants being wilted and affected with a sort of black rot, while those less seriously attacked are checked in their growth and as a result the crop yield is considerably lowered. Repeated experiments in the isolation and cultivation of the organism and the results of inoculation experiments are described in detail. Field experiments showed that plants from early-sown seed seemed more subject to disease, and moist soils also favored its development. Treating the seed grain with a 0.1 per cent solution of formalin seemed to restrict the spread of the disease in some of the experiments.

Concerning witches brooms of pear trees, F. MUTH (*Naturw. Ztschr. Land u. Forstw., 3* (*1905*), *No. 2, pp. 64–76, figs. 11*).—A description is given of witches brooms occurring on wild pear trees, the outgrowths being attributed to attacks of *Exoascus* sp.

Witches brooms of Quercus rubra, SOLEREDER (*Naturw. Ztschr. Land u. Forstw., 3* (*1905*), *No. 1, pp. 17–23, fig. 1*).—A description is given of witches brooms found upon the American red oak in a garden at Erlangen, Bavaria.

These growths have previously been reported as occurring on *Quercus ilex*, caused by the fungus *Exoascus kruchii*, and on *Q. lobata*, due to *E. quercus lobatæ*, but the cause of the witches brooms on the red oak is thought to be an entirely distinct species of fungus from those mentioned above. A list is given of trees known to be subject to these growths and, so far as known, the fungi which cause them.

[illegible] subsequent note, by K. von Tubeuf (same journal, No. 7, pp. 309, 310, figs. [illegible]ccurrence of these growths on red oak in other localities is mentioned.

Witches brooms of fir trees, K. von Tubeuf (*Naturw. Ztschr. Land u. Forstw., 3 (1905,) No. 6, pp. 253–260, figs. 5*).—Illustrated descriptive notes are given on a number of forms of witches brooms observed on fir trees.

Notes on Thelephora laciniata, K. von Tubeuf (*Naturw. Ztschr. Land u. Forstw., 3 (1905), Nos. 2, pp. 91, 92, fig. 1; 4, pp. 187–189, figs. 3*).—Brief accounts are given of attacks of *Thelephora laciniata* on young fir trees. The fungus, while not a true parasite, surrounds the lower parts of the seedling, ultimately causing its destruction. Very small seedlings are especially subject to attack. Moisture favors the development of the fungus. The seedlings should be thinned and stimulated by the use of fertilizers to make rapid growth. The same fungus is reported as injuring one-year-old beech seedlings.

Further studies on Melampsora occurring on willows in Switzerland, O. Schneider (*Centbl. Bakt. [etc.], 2. Abt., 15 (1905), No. 7–8, pp. 232–234*).—The results of inoculation experiments with *Melampsora ribesii-grandifoliæ* and *M. larici-reticulatæ* are given, in which notes are presented on the teleutospore and Cæoma stages of the fungi.

The occurrence of timber dry rot in Russia, L. von Lubimoff (*Ztschr. Österr. Ingen. Architekt. Ver., 1905, p. 363; abs. in Centbl. Bakt. [etc.], 2. Abt., 15 (1905), No. 9, pp. 269, 270*).—The rapid extension of railroad building, in which construction timber so largely enters, has served to call attention to the timber dry rot caused by *Merulius lachrymans*. The loss due to this fungus is said to be very great. To prevent its attack various preservatives have been employed, such as carbolineum, creosote, various tar oil and proprietary compounds, corrosive sublimate, etc., and notes are given on their use and relative efficiency.

A sclerotium disease of Forsythia, A. Osterwalder (*Ztschr. Pflanzenkrank., 15 (1905), No. 6, pp. 321–329, pl. 1*).—A description is given of a disease of the ornamental shrubs *Forsythia intermedia* and *F. suspensa* which is attributed to *Sclerotinia libertiana*, and the relation of certain conidia to the fungus is discussed. The stems, leaves, and flowers of the shrubs appear to be subject to attack of the fungus, which has proved quite destructive. The disease has been noticed for several years, but a careful search made in the spring of 1905 failed to show the wintering form of the fungus through the development of germinating sclerotia.

The resistance of various varieties of roses to rust, R. Ewert (*Naturw. Ztschr. Land u. Forstw., 3 (1905), No. 6, pp. 249–252*).—In 1903 investigations were begun at the Botanical Institute of Proskau on the rose rust due to *Phragmidium subcorticium*, and observations were made on the relative susceptibility of various classes and varieties of roses to the fungus, the observations being extended to cover the years 1903 and 1904.

Except in the hybrid perpetual class there was relatively little disease either year, and during 1904 there was much less than was observed the previous season. The meteorological data show that the rainfall from April to August in 1904 was only about one-third of the amount recorded in the previous year. The results of the observations are tabulated, from which it appears that the hybrid perpetuals as a class are more subject to attacks of *P. subcorticium* than any of the others studied.

A competitive test of spraying apparatus, J. Ritzema Bos (*Tijdschr. Plantenziekten, 11 (1905), pp. 81–96, pls. 2, figs. 8*).—A report is given of the jury designated to award the prizes of the Pomological Society of Holland for hand, knapsack, and power sprayers. The jury in making its award took into consideration the size, weight, apparent durability, cost, relative efficiency, fineness of spray, etc. First and second prizes and honorable mention were awarded in each class.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Bark ringing by woodpeckers and its relation to forest insects, G. FUCHS (*Naturw. Ztschr. Land u. Forstw., 3 (1905), No. 8, pp. 317–341, pl. 1, figs. 7*).—It has been shown by various authors that woodpeckers may attack healthy trees making a ring of punctures around the trunk and causing an outgrowth of a shelf-like structure at such points.

It appears that some of the species of woodpeckers are fond of the sap obtained in such outgrowths. It has also been observed that these ring structures may become infested with insects and are visited by woodpeckers in search of food. The author believes that on the whole woodpeckers are of more benefit in the destruction of injurious insects than harm as a result of injury to trees.

The pine squirrel as a forest pest, RUDOLF KOCH (*Naturw. Ztschr. Land u. Forstw., 3 (1905), No. 7, pp. 298–303, fig. 1*).—The author presents details regarding the nature of injury to the twigs of pines and fir trees by pine squirrels. The idea that these injuries are more often due to the attacks of *Garrulus glandarius* is without foundation.

The loss of terminal twigs through the agency of pine squirrels, K. VON TUBEUF (*Naturw. Ztschr. Land u. Forstw., 3 (1905), No. 11, pp. 476–478, fig. 1*).—According to observations made by the author all of the terminal twigs of pine trees eaten off by pine squirrels were subsequently replaced by lateral twigs which, however, grow considerably less rapidly than uninjured terminal twigs. The injury from pine squirrels is, therefore, considered as a serious matter.

Cases of bark injury due to the pine squirrel (Sciurus vulgaris), K. EPPNER (*Naturw. Ztschr. Land u. Forstw., 3 (1905), No. 3, pp. 112–120, figs. 3*).—According to the author's observations various species of pine are at times greatly injured by the pine squirrels gnawing off the bark and biting off the terminal branches. Several illustrations of this work of the pine squirrel are given which indicate that the injury from this squirrel may assume a serious character.

The determination of generic types, and a list of roundworm genera, with their original and type species, C. W. STILES and A. HASSALL (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 79, pp. 150*).—Much confusion has prevailed in zoological literature on account of the uncertainty regarding scientific names and the authors believe that this is partly due to a failure to designate type species for genera at the time of their erection. The discussion presented in this bulletin is designed to prevent, as far as possible, further confusion.

A historical review is given of the principles of type designation, together with copies of the British Association Code, the Dall Code, the code of the American Ornithologists' Union, and of the German Zoological Society, as well as other rules proposed by the various individuals and associations. The principles maintained in the bulletin are illustrated by application to a list of genera of roundworms.

The synonymy of Tænia, T. crassicollis, T. marginata, T. serrata, T. cœnurus, T. serialis, and Echinococcus, C. W. STILES and E. C. STEVENSON (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 80, pp. 14*).—This bulletin contains a detailed synonymy of species contained in the subgenera Tænia and Tæniarhynchus as well as the species socialis in the genus Multiceps.

International catalogue of scientific literature. N—Zoology (*Internat. Cat. Sci. Lit., 3 (1905), pp. XI + 438*).—The bibliographical references included in this volume are based mainly on literature published in 1903. It includes also certain articles published in 1901 and 1902. The bibliographical titles are grouped according to zoological classification.

The fauna of British India including Ceylon and Burma. Butterflies, I, C. T. BINGHAM (*London: Taylor & Francis, 1905, pp. XXII + 511, pls. 10, figs. 94*).—This volume is the first of a series of three which are being prepared by the author to

contain information regarding all the butterflies known to occur in British India. This work has been undertaken to supplement and complete that of de Nicéville. In the introduction to the volume the anatomy and classification of butterflies are briefly discussed. The families considered in this volume are Nymphalidæ and Nemeobidæ.

Report of the entomologist, C. P. GILLETTE (*Colorado Sta. Rpt. 1901, pp. 13-18, figs. 10*).—A summary is presented of the work thus far done at the station on codling moth. It appears that the eggs of the spring brood are deposited both on the fruit and leaves. Two applications of Paris green resulted in the saving of 25 to 90 per cent of the apples.

An examination has been made of a large number of bees with reference to the length of the tongue. The author has thus far been unable to find any evidence of a long-tongue race of Italian bees although several so-called long-tongue and red-clover bees have been examined. The length of the tongue in various races of bees ranges from 0.23 to 0.27 in. Brief notes are also given on sugar-beet insects and on a number of miscellaneous insects including Howard's scale, apple aphis, plum gouger, etc.

Dangerous insects and diseases and their treatment, L. R. TAFT (*Mich. Bd. Agr., Nursery and Orchard Insp. Bul. 1, pp. 16*).—The author briefly describes the purpose of the Michigan nursery and orchard inspection law and presents notes on San José scale, European fruit scale, scurfy scale, oyster-shell bark-louse, apple and peach aphis, cankerworm, crown gall, black knot, pear blight, peach yellows, little peach, and methods of fumigating nursery stock.

Insect pests in West Australian orchards and vineyards, F. LOWE (*Jour. Dept. Agr. West. Aust., 12 (1905), Nos. 4, pp. 302-307; 5, pp. 425-432*).—Attention is called to the climatic and other conditions which may exert an influence in determining the prevalence of insect pests and in affecting the relative abundance of parasitic insects. The subject of importation of parasitic insects is also discussed.

Particular attention is given to an account of the habits, life history, and means of combating the codling moth. In spraying for this insect the author recommends the use of Paris green at the rate of 1 oz. in 10 gal. of water to which 8 oz. of lime are added.

A preliminary list of the more injurious insects of Texas, with notes on distribution (*Texas Agr. and Statis. Rpt., 18 (1905), pp. 261-276*).—Some insect pests of the State are listed under the head of the plants which they affect.

Entomological notes, J. KOTINSKY (*Hawaii. Forester and Agr., 3 (1906), No. 1, pp. 8-11*).—Brief notes are given on the use of soap washes in the destruction of scale insects. A soap wash made in the proportion of 1 lb. of soap to 4 gal. of water has been used against the purple scale with satisfactory results in nearly all cases. Recommendations are also made regarding spraying apparatus.

A yearly programme in entomological practice for the orchard, H. A. GOSSARD (*Ohio Sta. Circ. 52, pp. 4*).—Recommendations are made regarding various insecticide operations to be applied in various months to apple, pear, quince, peach, plum, and cherry trees.

Spraying calendar, S. A. BEACH and E. E. LITTLE (*Iowa Sta. Bul. 85, pp. 39-53, figs. 2*).—In an introduction to this bulletin attention was called to the extent of damage caused by insects and fungus diseases in Iowa. The bulletin contains definite recommendations regarding the time for applying various insecticide and fungicide treatments and the materials and formulas to be used. The methods of preparing various spray mixtures are described.

The mealie stalk borer, C. W. MALLY (*Agr. Jour. Cape Good Hope, 27 (1905), No. 2, pp. 159-168, pl. 1*).—*Sesamia fusca* is a regular pest of corn in South Africa. The insect feeds upon corn, Kafir corn, and occasionally on other products. There appear to be only two well defined broods annually.

In controlling this pest it is recommended that old stalks should not be left in the field, but should be burned. In this manner the winter protection for the pest will be removed. Cornstalks may also be plowed under, but this is less effective, since they may not all be buried to a sufficient depth. Losses from the insect in question can not be materially reduced by late planting. A number of parasitic enemies are known, but they are not capable of reducing the number of the pest materially.

The preservation of maize during transport by the Clayton process (*Sci. Amer. Sup., 61 (1906), No. 1571, pp. 25177, 25178, figs. 10*).—Brief notes are given on the various uses of corn and the methods of transporting it from one country to another. In such transportation maize may be attacked by beetles, and for destroying insect pests in corn sulphur fumigation by means of the Clayton apparatus has been found very efficient. The apparatus is suited to disinfection of dwelling houses and other buildings as well as ships. The apparatus in question distributes sulphur dioxid, sulphur trioxid, and other gases through the infested material, and destroys insects in such material.

The control of micro-lepidoptera injurious to grapes in France, J. DEWITZ (*Centbl. Bakt. [etc.], 2. Abt., 15 (1905), No. 15-16, pp. 449-467*).—The most important micro-lepidoptera which attack grapes in France are *Tortrix pilleriana, T. ambiguella,* and *Eudemis botrana.*

In treating infested grapes in winter good results have been obtained from spraying with boiling water. Grapevines may also be sprayed with good results by the use of a mixture of lime, coal tar, caustic soda, and carbon bisulphid in water. Some of the insects in the winter stage may be destroyed by scraping the bark from grape trunks or by inclosing the trunks and fumigating with sulphur. Infested trunks may also be sprayed with a mixture of 10 kg. coal tar, 2 kg. oleic acid, 0.5 kg. caustic soda in 90 liters of water. In controlling these pests in summer some success has been had from the use of lantern traps, sticky substances, and various insecticides in weak solutions.

Combating phylloxera in 1904, D. CAVAZZA (*Ann. Uffic. Prov. Agr. Bologna, 11 (1904), pp. 41-74*).—A meeting was held in Imola at which measures were adopted regarding the control of phylloxera. As a result of this meeting measures were taken to determine the present status of infestation and the results of previous work in controlling the phylloxera. A committee was also appointed to study the distribution of American grape roots in the infested region and measures concerned with the control of the pest.

The grape phylloxera in Hesse, W. SCHUSTER (*Ber. Oberhess. Gesell. Nat. u. Heilk., 34 (1905), pp. 105-127, figs. 2*).—A brief historical statement is given regarding the introduction of the grapevine phylloxera into Hesse and its subsequent distribution. Particular attention is given to a statistical account of the prevalence of this pest from 1878 to 1902.

Natural enemies of the fruit fly, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 27 (1905), Nos. 3, pp. 309-319; 4, pp. 457-469*).—A visit was made to Brazil for the purpose of investigating fruit flies and their parasites with a view to the importation of possible beneficial parasites. The author and Mr. Fuller spent considerable time studying the conditions of the problem in localities where Mr. Compere had previously worked.

As a result of the investigations it is concluded that the efficiency of natural enemies of the fruit flies found in Brazil has been greatly overestimated by Mr. Compere. The fruit fly *Ceratitis capitata* is a serious pest in various parts of Brazil and appears not to be held in check by its natural enemies. Another serious fruit fly pest is *Anastrepha fratercula* and is also not greatly affected by natural parasites. The staphylinid beetle reported by Mr. Compere as an important enemy of the fruit fly was not found at all by the author.

In search of parasites, G. Compere (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 6, pp. 547, 548*).—A short popular account is given of a recent visit to China in search of the parasites of red scale and purple scale and the announcement is made that in the near future an attempt will be put forth to secure parasites of the potato moth and woolly aphis.

Some tree and wood-infesting insects. Cabbage snakes, H. Garman (*Kentucky Sta. Bul. 120, pp. 45-81, pls. 4, figs. 6*).—The elm-leaf beetle has gradually spread over the eastern part of the State, where it has destroyed many neglected elms, particularly the imported species.

The use of bands about the trunks of elms is without effect in keeping the insects away from foliage, but sticky bands or other obstructions may be used for attracting the insects at the time of pupation. In one case more than 13,000 beetles were destroyed in this way about the base of a single tree. Just as effective work, however, may be accomplished by the use of scalding water or kerosene from time to time. The beetles on the foliage may be destroyed by the use of Paris green at the rate of 1 lb. per 100 gal. of water, together with 1 lb. of slaked lime or arsenate of lead at the rate of 3 to 4 lbs. per 100 gal. of water.

Notes are presented on insects affecting oak and other trees. Oaks are attacked by leaf miners and *Kermes pubescens*. The latter may be destroyed by spraying with lime-sulphur-salt wash. Brief accounts are presented of walnut worm, cottonwood leaf beetle, vagabond gall louse, poplar leaf tyer, willow leaf beetle, willow flea beetle, willow slug, apple-tree measuring worm, cicadas, June bugs, and other forest insects.

Considerable injury is reported to casks from the attacks of bark beetles, particularly *Monarthrum fasciatum* and *M. mali*. The wood of vinegar barrels, beer kegs, wine casks, etc., was perforated by small holes which were most numerous near the hoops and at the joints between the staves. Since these insects bore into the wood in hope of finding fungus upon which to live, it is desirable to treat the casks so as to destroy the fungus. For this purpose Bordeaux mixture, copper sulphate, lime-sulphur wash, or bisulphite of lime are useful. The attack of the beetles is largely prevented by scalding the casks and treating them with lime.

On account of the unusual popular interest aroused in cabbage snakes, some attention was given to this subject. The term "cabbage snake" appears to have been applied to a slender species of Mermis which is parasitic in the bodies of a number of insects. In some localities the term has also been used for *Geophilus bipunticeps*.

The black locust tree and its despoliation, C. A. White (*Pop. Sci. Mo., 68 (1906), No. 3, pp. 211-218*).—On account of the fact that the black locust is a rapidly growing tree it has recently been planted on an extensive scale for the production of railroad ties and for other purposes. The author believes, however, that on account of an attack of three especially injurious insects on the plantations, these trees are doomed to failure.

These pests are a leaf miner, gall insect, and the locust borer (*Cyllene robiniæ*). The last-named insect is the most injurious, burrowing through the trunk and larger branches, and rendering the wood unfit for use. Infestation by this pest is not observed at once; in fact the tree may be practically ruined for economic purposes without injury to the bark. The locust borer is exceedingly injurious wherever the black locust occurs in this country except in parts of California. Notes are given on the habits and life history of this pest and on possible remedies.

No effective remedies, however, have been devised. The application of repellent washes to the trunks of trees is suggested, but would be rather expensive.

The root-louse of the Norway spruce, A. Jacobi (*Tharand. Forstl. Jahrb., 55 (1905), No. 3, pp. 177-197, pl. 1*).—The habits and life history of *Rhizomaria piceæ* are described in considerable detail.

This insect appears on the roots of the Norway spruce, and, when present in large numbers, sucks the juice from the roots to such an extent that the trees are greatly weakened, or, in some cases, killed outright. In combating this pest, the best results have been obtained from the use of carbon bisulphid mixed with molasses and placed in the soil about the roots of infested trees. The molasses serves to hold the carbon bisulphid for some time, allowing it gradually to escape and produce its effect upon the insects. The insecticide may be injected into the soil by means of a syringe or placed in a furrow around the trunk.

The number of annual generations among the bark beetles, E. Knoche (*Naturw. Ztschr. Land u. Forstw., 3 (1905), Nos. 9, pp. 353–368; 10, pp. 401–415*).—The literature relating to the biology of various species of bark beetles is critically reviewed.

The author concludes from the study of literature and from his own observations that the question whether a given species of bark beetle produces 1 or 2 generations annually depends not so much upon the species as upon the temperature of the locality where the beetle is found. Nevertheless under given conditions different species do not vary in this respect, but each one shows the same number of generations from year to year.

Tomicus typographus, O. Nüsslin (*Naturw. Ztschr. Land u. Forstw., 3 (1905), Nos. 11, pp. 450–468; 12, pp. 481–493, fig. 1*).—This insect is described in its various stages with special notes on its occurrence in Herrenwies and Pfullendorf in 1905. In order to control this beetle it is very desirable that infested trees should be cut and removed from the forest before the beetles have emerged. This and the maintenance of trap trees are about the only practical remedies for the control of the pest.

Pissodes harcyniæ, G. Fuchs (*Naturw. Ztschr. Land u. Forstw., 3 (1905), No. 12, pp. 507, 508, pl. 1*).—This insect is reported as occurring in large numbers in June on pine trees. As a result of the injury due to the beetle, infested trees became subsequently diseased through the attacks of *Trametes pini*.

Lophyrus similis, W. Baer (*Naturw. Ztschr. Land u. Forstw., 4 (1906), No. 2, pp. 84–92, figs. 3*).—This sawfly is described with notes on some related species and on anatomical features which serve to distinguish it from the other species. Particular attention is given to the biological and morphological differences between *L. similis* and *L. pini*.

Progress made in exterminating the fever tick in North Carolina, T. Butler (*Raleigh: N. C. Dept. Agr., 1906, pp. 4, figs. 3*).—The attention of cattle raisers is called to the fact that during the past 4 years 10 counties in North Carolina have been freed from cattle ticks and placed above the Federal quarantine line. The author considers that his experiments have demonstrated the feasibility of exterminating cattle ticks in all sections where stock laws prevail. It is believed that the ticks may be exterminated at a smaller cost than the annual loss due to cattle ticks in the affected regions.

Fowl tick experiments, F. H. Robertson (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 6, pp. 561–563*).—It was found that fowl ticks remain alive at least 2 years and 3 months without the presence of any fowls from which to derive nourishment. In these experiments the ticks were maintained in small pill boxes which were practically air tight. In the nymph stage ticks may live for 2 months without food.

A classification of the mosquitoes of North and Middle America, D. W. Coquillett (*U. S. Dept. Agr., Bur. Ent. Bul. 11, tech. ser., pp. 31, fig. 1*).—On account of the requests received by this Department from students of entomology, physicians, and sanitary officials regarding the identification of mosquitoes in various parts of the country, the present bulletin is prepared to furnish information along this line. The external anatomy of mosquitoes is briefly described, together with notes on the subfamilies, a table for identifying these subfamilies, and also analytical

tables for the identification of the genera and species of mosquitoes recognized in North and Middle America

Household insects, W. LOCHHEAD (*Canad. Ent., 38 (1906), No. 3, pp. 65-70, figs. 3*).—Notes are given on the habits and life history of house flies, mosquitoes, fleas, bedbug, carpet beetles, clothes moths, larder beetles, mites in cheese, ham, and flour, flour beetles, meal worms, and red ants. Practical methods of combating these pests are suggested for each species.

Report of the committee on apiary, J. W. NELSON (*Ann. Rpt. Penn. Dept. Agr., 10 (1904), pp. 381-383*).—The winter of 1904 is said to have been one of unusual severity for bees. Notes are given on the quality of honey obtained from various kinds of plants with particular reference to its color and taste. Attention is called to the desirability of a stringent law in Pennsylvania regarding the eradication of foul brood.

Apiculture in Cuba, E. W. HALSTEAD (*Estac. Cent. Agron. Cuba Circ. 20, pp. 11, pls. 3, fig. 1*).—Brief historical notes are given on the development of apiculture in Cuba, the management of bees, artificial swarming, introduction of queens, extraction of honey, foul brood, and other diseases of bees.

Age at which bees first carry pollen, C. C. MILLER (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 3, pp. 245, 246*).—The difficulty experienced in determining this matter is considerably increased by the fact that bees so often attempt to rob honey from other colonies and in many instances become confused and enter the wrong hives. The author made a number of observations on this subject and will continue his investigations.

Japan's three silk crops, F. A. VIVANTI (*Yokohama: Japan Gazette Press, 1905, pp. 10*).—The great increase in the silk industry in Japan during the past 30 years is attributed by the author to the improved methods which have been adopted, so that three crops of silkworms may be fed annually.

Formerly sericulture was confined almost entirely to the northern provinces of Japan, but now this industry flourishes throughout the islands. The method by which the three crops of silkworms are fed annually is based on the use of cold storage. A large supply of eggs are placed in cold storage in the fall and carried over to the following spring. In May, when the first mulberry leaves appear, about 65 per cent of the eggs are taken out of cold storage and hatched. After about one month one-half of the remaining eggs are in turn taken out and hatched, thus producing the summer crop of cocoons which are ready for reeling in July or August. About a month later, the rest of the eggs are taken from cold storage and hatched, so as to produce the autumn, or third crop.

Streptococcus bombycis in relation to emaciation and flaccidity of the silkworm, S. SARTIRANA (*Centbl. Bakt. [etc.], 1. Abt., Orig., 40 (1905), No. 2, pp. 207-211; 40 (1906), No. 3, pp. 331-336*).—The author studied the morphology and biology of this micro-organism with special reference to its connection with emaciation in silkworms.

As a result of numerous inoculation experiments, it is concluded that the micro-organism in question must be considered as the only specific cause of this disease. It is found chiefly in the alimentary tract, and causes local lesions, which lead to chronic enteritis. Flaccidity, however, can not be considered as a peculiar disease caused by one micro-organism alone; it is rather a mixed infection due to a number of micro-organisms, including streptococci.

FOODS—HUMAN NUTRITION.

Food and diet in health and disease, R. F. WILLIAMS (*Philadelphia and New York: Lea Bros. & Co., 1906, pp. X+392, fig. 1*).—This volume, which is designed as a text-book for students, has two main divisions, the first treating of food in health and the second of food in disease.

Available data are summarized regarding the chemistry of foods, the physiology of digestion, the changes brought about by cookery, the characteristics of different food groups, feeding in infancy and old age, as well as special diets suited to different diseases, preparation of foods for invalids, and related questions, the volume as a whole constituting a concise summary of the subject of nutrition from the physician's standpoint.

In his introduction the author states that the first half of the volume, which deals with nutrition and food in health, is largely based on the results of the nutrition investigations which have been carried on under the auspices of the Office of Experiment Stations.

A new method of indicating food values, I. FISHER (*Amer. Jour. Physiol., 15 (1906), No. 5, pp. 417–432, figs. 23*).—A system of expressing the nutritive value of food is described in which a quantity yielding 100 calories is selected as the basis for comparison. The author believes that this gives a better idea of the relative nutritive value of different foods than the usual method of expressing percentage composition.

A method is described in which a right-angled triangle is divided in such a way that composition is expressed graphically. The author has devised an instrument by which the nutritive value of a food or diet may be estimated according to his system.

An inquiry into the extent of underfeeding amongst the school children of Blackburn, A. GREENWOOD (*Blackburn, Eng.: Times Printing Works, 1905, pp. 76*).—From a careful study of the existing conditions it is stated that probably not more than 1.3 per cent of the Blackburn school children are underfed. The author believes that "considerable waste occurs in many homes through a lack of knowledge as to cheap nutritious articles of diet and economical cooking. . . . It is important that the elder girl scholars should be taught the preparation and cooking of such meals as are available in a workingman's home."

The function of cellulose in the diet of man, I, H. LOHRISCH (*Ztschr. Physiol. Chem., 47 (1906), No. 2–3, pp. 200–252*).—A large amount of experimental data is reported on the digestibility of cellulose supplied by a number of common food materials.

The results obtained showed that with normal digestive apparatus cellulose is more or less well digested, and indeed under some circumstances is thoroughly digested, the thoroughness of digestion being indirectly proportional to its hardness. On an average the normal subjects studied by the author digested 57.9 per cent of the cellulose, patients suffering from chronic constipation 81.4 per cent, and those suffering from other diseases amounts to considerably less than normal.

The question of cellulose digestion, the author believes, will not be understood until the ferments inducing it, at present unknown, are identified and studied. The article contains a review of earlier investigations and a bibliography.

The influence of the dietary on the constituents of the urine, A. DESGREZ and J. AYRIGNAC (*Compt. Rend. Soc. Biol. [Paris], 60 (1906), No. 13, pp. 616–618*).—The proportion of different constituents of the urine and their relation to each other was studied on an absolute and mixed milk diet, milk and egg diet, vegetarian diet, and mixed diets containing large and small amounts of meat.

The ratio of nitrogen of urea and total nitrogen reached its minimum in the vegetarian diet and its maximum in the absolute milk diet. The ratio of uric acid to urea was greatest on a vegetarian diet and least on a mixed diet containing large

amounts of meat. The phosphoric acid and sulphur constituents of urine were also studied.

The effect on metabolism of overfeeding protein, M. SCHREUER (*Arch. Physiol.* [*Pflüger*], *110* (*1905*), *No. 3-4, pp. 227-253*).—The investigations showed that feeding large quantities of protein did not permanently increase the protein content of the body. An increased oxygen consumption was noticed in experiments with dogs when large amounts of protein were taken, which indicated an increased cell activity, but this increase in the material stored in body cells was not found to be permanent.

Protein feeding and the estimation of glycogen, E. PFLÜGER (*Arch. Physiol.* [*Pflüger*], *111* (*1906*), *No. 7-8, pp. 303-308*).—For exact estimations of glycogen the author insists that his cuprous-oxid method should be used.

Some considerations on proteid diet, L. F. BARKER and B. A. COHOE (*Jour. Biol. Chem.*, *1* (*1906*), *No. 2-3, pp. 229-238*).—Using Hausmann's method, the amid, melanoidin, diamino, and monamino nitrogen was determined in veal cutlet, pork chop, beef sirloin, beef tenderloin, beef neck, heart, liver, thymus, chicken, and trout, with a view to determining something regarding composition and differences in food value. The various forms of nitrogen were rather evenly distributed in the foods analyzed.

The chemistry of flesh, IV. A study of the proteids of beef flesh, P. F. TROWBRIDGE and H. S. GRINDLEY (*Jour. Amer. Chem. Soc.*, *28* (*1906*), *No. 4, pp. 469-505*).—The conclusions drawn from an extended chemical study of the proteids of beef flesh were in effect as follows:

The total acidity of aqueous extracts of flesh varies between comparatively wide limits, the minimum being 0.66 per cent, the maximum 1.07 per cent, and the average 0.85 per cent, calculated as lactic acid and expressed in terms of the fresh substance of the meat. The residues of flesh which are left after the complete extraction with cold water are distinctly acid to litmus and to phenolphthalein. On the other hand, the insoluble proteids of flesh upon digestion with decinormal hydrochloric acid at ordinary temperature combine with it and neutralize its acid properties.

Analyses made by the authors show that 13.56 per cent of the total proteid existing in lean beef flesh is soluble in cold water. Of this total soluble proteid 90.04 per cent is in a form which is coagulable by heat from a neutral solution, 8.40 per cent exists as albumoses and a very small quantity apparently exists in the form of peptones. Presumably, the albumoses and peptones do not exist as such in the original flesh. During the coagulation of an aqueous extract of flesh there is an increase in its acidity. Reduction of the acidity of aqueous extracts of flesh facilitates coagulation of the proteids.

There are no well-defined degrees of temperature at which different coagula of aqueous extracts of flesh separate. The complete removal of the proteid coagulating at any fixed definite temperature requires long application of heat. Further, the lower the temperature at which a coagulum is separated, the longer the time of heating required to effect complete coagulation.

The chemical composition of the different fractional coagula of the aqueous extracts of raw flesh is remarkably constant. They are also quite similar as regards their chemical constitution judging from the results of their hydrolysis.

Raw flesh which has been completely freed from proteids soluble in cold water contains two classes of proteid substances, those which are soluble in a 10 per cent solution of ammonium sulphate and those which are insoluble in this medium.

For earlier work see E. S. R., 17, p. 886.

The globulin of muscle fibers, L. MOROCHOWETZ (*Physiol. Russe*, *4* (*1905*), *No. 61-67, pp. 42-52*).—A historical account is given of the globulin of lean meat (myoglobin), the chemistry of the subject, and related questions, and the results of studies of preparation, characteristics, and properties reported. According to the author,

if repeatedly dissolved in ammonium-sulphate solution and precipitated with this or some other salt a product is finally obtained which, after dialysis, contains only an inappreciable quantity of ash.

The globulin of egg yolk, L. MOROCHOWETZ (*Physiol. Russe, 4 (1905), No. 61–67, pp. 53–59, fig. 1*).—Historical and other data are summarized regarding globulin of egg yolk (vitelloglobin) and studies of its preparation and properties reported. When free from fat and other contaminating bodies, this globulin did not differ from other globulins in respect to its solubility in a solution of common salt or other salts.

The liver as a storehouse for protein, W. SEITZ (*Arch. Physiol. [Pflüger], 111 (1906), No. 7–8, pp. 309–334*).—In experiments with chickens the conclusion was reached that protein is stored in the liver.

The effect of constituents of low-grade flour on the extraction of gluten and upon bread-making properties, LINDET and L. AMMANN (*Ann. Chim. Analyt., 10 (1905), No. 12, pp. 454–456; 16–17, pp. 1005–1014*).—The difficulty experienced in extracting gluten of low-grade flour, according to the investigations reported, is due to its acidity and to the presence of a mucilaginous substance and of small carbohydrate particles derived from the bran, which become mixed with the gluten particles and prevent agglutination. To facilitate the determination of gluten this bran material should be removed by the action of ferments and the acid and mucilaginous material by extraction with water.

In the second paper, which gives a more extended account of the investigations, the authors conclude that glutenin is made up of fine particles which are not very coherent embedded in a mass of gliadin which imparts the agglutinating properties. The effect of heating at different temperatures and related questions are considered.

The acidity of bread and its causes, H. STIEGELER (*Pure Products, 2 (1906), No. 4, pp. 183–186*).—The acid reaction of bread is due either to free organic acid or to acid potassium phosphate. The formation of acid in flour and leaven, as pointed out, must be attributed to micro-organisms and particularly to bacteria, and a number of sorts of bacteria which produce acid in bread are described.

"When pure yeast is employed in the preparation of the bread, the product exhibits a low acidity; the dough is then so rapidly raised by the growth of the yeast cells and of their fermenting power, that the acid-forming bacteria have no chance to develop. This is the case also with rye bread, whose normally rather high acidity is not derived from the flour. It is the use of impure yeasts, of sour milk and of rancid butter which produces the high acidity in bread leavened with yeast. The acids of bread do not appear to lower its nutritive value, yet a very sour bread will interfere with the digestion of many persons."

The nutritive value of Corsican chestnut flour, P. COMTE (*Jour. Pharm. et Chim., 6. ser., 22 (1905), No 5, pp. 200–210, fig. 1*)—Composition, charateristics, and microscopical structure of Corsican chestnut flour are considered, as well as its nutritive value and place in the diet. According to analyses it contains somewhat less protein and somewhat more nitrogen-free extract than wheat flour. The author considers it a palatable and valuable food product.

Study of apple marc, W. D. BIGELOW and H. C. GORE (*Jour. Amer. Chem. Soc., 28 (1906), No. 2, pp. 200–207*).—The data reported show that the hot-water extract, constituting 40 per cent of apple marc, consists of one carbohydrate complex, a galacto-araban.

"The carbohydrate complexes in case of the alcohol precipitate of apple must, and in case of the alcohol precipitate of second pressing ciders, are both higher in galactan, relative to the pentosan content, than the hot-water extracts of apple marc. The treatment with boiling water lessens the yield of crude fiber and cellulose, and at the same time gives a purer fiber and a purer cellulose." (See also E. S. R., 17, p. 465.)

Changes in the composition of the fruit of cucurbits, LECLERC DU SABLON (*Compt. Rend. Acad. Sci. [Paris], 140 (1905), pp. 320, 321*).—The sugar, starch, and

water content of different sorts of cucurbit fruits was determined before, during, and after maturity. The sugar, which was abundant in the unripe fruit, diminished during the ripening processes, increased after the fruit was ripe and again diminished. The starch content increased until the fruit was harvested and then diminished, while the water content first increased, then diminished markedly at maturity, and afterwards increased.

The chemistry of celery (Apium graveolens), I, M. Bamberger and A. Landsiedl (*Monatsh. Chem., 25 (1904), pp. 1030–1034; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 10 (1905), No. 10, p. 619*).—In the roots of tuberous rooted celery the authors report 0.48 per cent asparagin, and a smaller amount of tyrosin in addition to mannit. Leucin was not found.

The absorption of sulphurous acid from the air by meat, A. Kickton (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 6, pp. 324–328*).—The experiments showed that when sulphurous acid was present in air meat would absorb it, the surface containing considerably more than the interior.

Evaporated cream (*Mo. Bul. Bd. Health Mass., n. ser., 1 (1906), No. 3, p. 61*).—Determinations of fat showed that so-called evaporated creams were merely unsweetened condensed milks, having somewhat the consistency and appearance but neither the taste nor physical characteristics of cream.

The artificial coloring of mustard, P. Köpcke (*Pharm. Centralhalle, 46 (1905), p. 293; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 6, pp. 349, 350*).—The method of detection suggested depends upon the extraction of the coloring matter with ammonia and showing the presence of artificial coloring matter by dyeing a sample of woolen goods.

Honey vinegar, J. J. Hofmann (*Pharm. Weekbl., 42 (1905), pp. 704, 705; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 6, p. 356*).—Honey vinegar is manufactured on a commercial scale in Holland. A number of samples were examined and found to possess an agreeable aroma and taste.

Report of work in the food and drug laboratory, H. E. Barnard and J. N. Hurty (*Mo. Bul. Ind. Bd. Health, 7 (1905), No. 11, pp. 130–144; 8 (1906), No. 1, pp. 5–21*).—Over 50 per cent of the foods, condiments, and beverages examined under the provisions of the State pure food laws were found to be adulterated.

The pure food and drug laws of the State of Indiana (*Mo. Bul. Ind. Bd. Health, 7 (1905), Nos. 7, pp. 75–88; 8, p. 95*).—The legislative enactments regarding pure food and drugs in the State of Indiana and the food and drug rules of the State Board of Health are quoted.

The pure food law in Germany, its origin and growth, and its effect upon the commercial food industry and upon diet, A. Juckenack (*Deut. Vrtljschr. Öffentl. Gsndhtspflege, 37 (1905), pp. 678–688; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 6, pp. 358, 359*).—The growth, development, and results of the German pure food law are discussed. In the author's opinion this law is responsible for a great improvement in the quality of food products and in food considered from a sanitary standpoint.

ANIMAL PRODUCTION.

The composition of some Hawaiian feeding stuffs, E. C. Shorey (*Hawaii Sta. Bul. 13, pp. 23*).—Proximate and ash analyses are reported of a number of samples of sorghum, sugar cane tops, millet, Kafir corn, wild and cultivated grasses, alfalfa, wild cowpea, cowpea, 2 sorts of Desmodium, pigweed, sow thistle, *Commelina nudiflora*, *Bidens pilosa*, prickly pear, *Acacia farnesiana*, banana tops and butts, taro tops, sweet potato tops, ti leaves (*Cordyline terminalis*), cassava roots, brewers' grains, molasscuit, algeroba beans (whole beans—pods and seeds), rice bran, rice polish, and cocoanut meal. In addition to the usual constituents the percentage of total, proteid, and amid nitrogen was determined.

A fact of special interest brought out by the bulletin is that a number of Hawaiian feeding stuffs, particularly those belonging to the grass family, are deficient in lime, and that the failure to obtain the best results, which has sometimes been noticed with a ration which was apparently well balanced, may be attributed to this cause. In order to secure the best results in bone development, health, etc., the author believes that such feeding stuffs should be supplemented by others richer in lime, as leguminous plants, algeroba beans, and sugarhouse by-products, or by the use of more lime either in the drinking water, mixed with the feeds used, or applied to the soils producing the forage crops.

"While the analyses reported in this bulletin are not considered sufficiently numerous to warrant any extended comparison of Hawaiian feeding stuffs with one another or with those of other regions, or to justify elaborate discussion of the best ways of utilizing the various feeding stuffs in Hawaiian practice, they do show that the Hawaiian feeder has at his command a quite large and varied assortment of feeding stuffs, many of which are of high nutritive value, and it is believed that the information given in the bulletin will aid the feeder in selecting from the feeding stuffs available those which will give him the cheapest and most efficient rations for his stock."

Analysis of fodder plants, E. A. MANN (*Jour. Dept. Agr. West. Aust., 13 (1906), No. 2, pp. 142–145*).—Among the plants analyzed were black boy leaves, grass tree leaves, African wonder grass, and *Eragrostis pilosa*.

Feeding stuff inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 129, pp. 81–100*).—Under the State feeding stuff law analyses were made of a number of samples of cotton-seed meal, cotton-seed feed, linseed meal, viscid oil meal, gluten meals and feeds, distillers' grains, molasses feeds, mixed and proprietary feeds, corn meal, hominy meal, wheat bran, wheat middlings, mixed wheat feed, oats, beef scrap, and similar goods.

With the exception of samples of cotton-seed meal submitted by jobbers for the purpose of learning their quality, the authors state that they found no cotton-seed meal which was below the Cotton-seed Crushers' Association standard for prime goods.

Inspection of concentrates, J. B. LINDSEY ET AL. (*Massachusetts Sta. Bul. 108, pp. 51*).—The concentrated feeds analyzed under the State law include blood meal, cotton-seed meal, linseed meal, oil meal, viscid oil meal, gluten meal and feed, brewers' and distillers' dried grains, malt sprouts, wheat middlings, mixed wheat feeds, wheat bran, dairy feeds, sugar feeds, rye feeds, buckwheat feeds, calf meal, corn meal, hominy meal, provender, corn and oat feeds, oat feeds, dried beet pulp, corn bran and similar goods, cereal breakfast food by-products, meat scraps and similar goods, dried fish, granulated milk, poultry feeds, and alfalfa and clover meals.

The various corn and oat feeds, the authors state, may be divided into two classes, namely, those consisting largely of oat refuse with some corn, frequently of low quality, and occasionally a little red dog middlings, and those consisting principally of hominy, to which has been added more or less oat offal. The feeding stuffs included in the first class have a rancid, bitter taste, while those in the second group are generally sweet and more attractive. Such goods are inferior to clean, bright corn or hominy meal, yet, as the authors point out, they cost nearly or quite as much.

"Alfalfa [meals], as well as clover meals, are now obtainable for winter feeding. The former should carry 18 per cent protein, and the latter 12 per cent. Preference should be given to bright, clean lots, free from excess of coarse, woody stalks. The price ($1.80 a hundred) is rather in excess of their value. Poultrymen, by raising corn and clover, can considerably reduce their outlay for food. . . .

"Molasses may constitute one-sixth to one-fourth of the grain ration for horses ([illegible] pint to one quart daily). A larger quantity tends to make them logy. The [illegible] amount may be fed daily as a constituent of the grain ration for dairy stock."

The inspection of feeding stuffs in 1905, F. W. MORSE (*New Hampshire Sta. Bul. 124, pp. 147–152*).—Analyses are reported of 84 samples of cotton-seed meal, linseed meal, gluten meal, gluten feed, distillers' grains, hominy feed, compounded cattle foods, vegetable poultry foods, animal meal and similar poultry foods, and bone meal.

The following statements are quoted from the discussion of the analytical data:

"There were found to be 3 distinct classes of cotton-seed meal, according to the percentage of protein, being guaranteed, respectively, to contain 38.5 per cent, 41 per cent, and 43 per cent. . . . The prices were practically alike for all three grades. This is an injustice to the consumer because the lowest grade contains more lint and hulls than the highest grade. The consumer, however, can protect himself by reading the tags on the sacks. . . . Two brands of so-called mixed feed were collected, which were not pure wheat products. One contained corncob and gave an exceptionally high fiber, while the other was made up largely of screenings, finely ground. They complied with the law in bearing proper labels, but one was inferior to its stated composition. . . .

"There are no failures on the part of any of the poultry foods to reach the percentage guaranteed, while some of the animal meats and scraps overrun heavily, especially in fat. Excessive amounts of fat would not seem advantageous for laying hens, however."

Licensed concentrated feeding stuffs, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Bul. 134, pp. 17–23, 27–30*).—A list of the feeding stuffs licensed for sale during the calendar year 1906 is given, together with the guaranty of their protein and fat content. The text of the State feeding stuff law is quoted.

The nutritive value of the nonproteid nitrogen compounds in feeding stuffs, E. SCHULZE (*Jour. Landw., 54 (1906), No. 1, pp. 65–81*).—A summary and discussion of available information concerning the nonproteid constituents of feeding stuffs. The author considers that many of these constituents possess considerable nutritive value, while others are of little or no importance in nutrition. In the latter group, asparagin and perhaps glutamin are included.

Experiments on the value of asparagin and lactic acid in the feeding of Herbivora, O. KELLNER (*Verhandl. Gesell. Deut. Naturf. u. Aerzte, 76 (1904), II, 1. Abt., p. 145; abs. in Centbl. Agr. Chem., 35 (1906), No. 1, pp. 45–48*).—From experiments with sheep the conclusion was reached that neither asparagin nor lactic acid bore any part in the gains which were made. The author believes that asparagin has a value in that it tends to prevent the lowering of digestion noted with a very low proteid diet and so acts indirectly and in a limited way as a protector of protein.

Digestion experiments with forage plants, H. G. KNIGHT (*Wyoming Sta. Rpt. 1905, pp. 52–60*).—Experiments on the digestibility of alfalfa hay by sheep gave the following average coefficients: Dry matter, 63.39; protein, 79.67; fat, 41.20; ether extract, 74.08; crude fiber, 44.84, and ash, 56.17 per cent.

Feeding beef cattle in Mississippi, A. SMITH and C. I. BRAY (*Mississippi Sta. Bul. 92, pp. 24, figs. 10*).—To study the relative merits of feeding in a warm stable and an open yard and to compare a mixed ration of hay and grain with one of cotton-seed meal and hulls only, a feeding test was undertaken with 5 lots of steers. Three of the lots were made up of 5 animals, one of the lots of 7, and one of 3 animals. The cattle in the latter lot were scrubs and the others thrifty animals and medium feeders. Three of the lots were fed in a stable and two in yards, one with and one without an open shed for shelter, the mixed ration and the cotton-seed meal and hull ration being so arranged that each was tested under the 2 conditions of feeding. The test covered approximately 14 weeks.

Considering the thrifty animals fed in stalls the average gain on the mixed ration was 201 lbs. per steer and on the ration made up of cotton-seed products 185 lbs. per steer, the cost of a pound of gain in the 2 cases being 8.5 cts. and 6.1 cts. The scrub

steers fed in a stall made an average gain of 130 lbs. at a cost of 10.7 cts. per pound. The steers fed the mixed ration in a yard gained on an average 196 lbs. at a cost of 9.13 cts., and the similar lot fed the ration of cotton-seed products gained 146 lbs. at a cost of 8.2 cts.

The manure may be more readily saved when the steers are fed in stalls. Its estimated value in the test reported was $80.

Following are some of the authors' conclusions:

"The comparison between the stable versus open yard system while showing some advantage in favor of the stable method really indicates that a combination of the best features of both systems is preferable. This could be done by allowing the cattle to run in large sheds with a solid tight floor which should be well bedded, and the manure all saved. If desired, outside yards connected with these sheds could be provided, so that the cattle could have some exercise and plenty of fresh air. One of the secrets of successful cattle feeding is in making them as comfortable as possible.

"Where cotton-seed meal and hulls can be purchased at a reasonable price, they prove to be very cheap feeds for fattening steers. No bad effects result from feeding cotton-seed meal for such short periods as this, and it remains to be seen whether any ration can be compounded exclusive of good silage, which can equal it as an inexpensive feed.

"Dairy farming has many points of superiority over beef raising, but to farmers who are not close to a good market and are handicapped by lack of available and steady labor, the breeding and feeding of cattle will offer many inducements. That it is a profitable business in the South is shown by the low cost of raising cattle, economy in producing suitable feeds, and the inexpensive buildings required. With a good pure-bred beef sire, a herd of native cows, and plenty of pasture land, a farmer may in 2 or 3 years' time develop a good grade beef herd, which will largely increase his profits and maintain the fertility of the soil."

Summary of swine feeding, 1904-5, G. E. Morton (*Wyoming Sta. Rpt. 1905, pp. 44-47*).—Many believe that corn is necessary for pork production, and a comparison of wheat and corn was made with 2 lots of 3 pigs each. In 11 weeks the total gain on wheat was 342 lbs. and on corn 229 lbs.

In a second test wheat and alfalfa hay with and without roots were studied with 2 lots of 2 pigs each. In 13 weeks the lot fed roots gained 183 lbs. and the lot without roots 185 lbs. "Evidently the roots fed did no good in anyway; they were simply an additional expense."

Judging by both tests "straight wheat feeding gives the best gains of any of the rations tabulated, but it also involves very heavy grain feeding [8 to 24 lbs. per day at the end of the test] to get the gain."

"An answer to the question whether this extra gain and less amount of concentrates is offset by the cost of the alfalfa hay depends upon the comparative cost of the feeds in a given locality."

A sow weighing 341 lbs. was fed for 14 weeks beginning December 3, alfalfa hay and roots only, consuming on an average 6 lbs. of the hay and 6 to 24 lbs. of the roots per day. At the end of the period she had lost 7 lbs

Three sows fed corn, shorts, and alfalfa hay gained 122 lbs. in 6 weeks. "The gain shown . . . is good and the sows were apparently put in good condition for pigging by this ration. One sow gave birth to 7 living pigs and 1 dead pig; the other gave birth to 5 living and 3 dead. Further experimentation will be required to determine whether the ration was responsible for the stillbirths."

Corn and shorts, corn and alfalfa hay, and wheat and corn each with alfalfa hay chopped in swill were compared with 4 lots of 3 pigs each, averaging 65 lbs. each in weight. The gain on corn and shorts 1:2 was 61 lbs., and on corn and alfalfa 1:2, 19 lbs. On each of the rations made up of grain, alfalfa hay, and swill there was a loss

of 3 lbs. "The alfalfa rations for young growing pigs were lamentable failures. The pigs grew scrawny and lost weight."

Supplements to corn for fattening hogs, E. B. FORBES (*Missouri Sta. Bul. 67, pp. 19*).—Using 15 lots of 4 or 5 pigs each concentrated feeds in varying proportions and combinations were compared as supplements to corn meal for dry-lot fattening. Ear corn was also compared with corn meal, both being fed with linseed oil cake.

The tests were made in the winter and covered 29 to 90 days, being preceded by preliminary periods of 4 to 6 weeks. The pigs were confined in small pens with a shed, but were not protected from wind and cold. The grains were ground and mixed to a slop with water except in the comparison of ear corn and ground corn.

When corn meal was supplemented by wheat middlings and linseed meal with and without germ oil meal and gluten meal and feed for 90 days, the gain ranged from 0.971 lb. per head per day on corn meal and wheat middlings 2:1 to 1.430 lbs. on corn meal and linseed meal 5:1, and the grain eaten per pound of gain from 4.45 lbs. on the latter ration to 5.18 lbs. on the former.

When linseed meal and wheat middlings were compared in varying proportions as supplements to corn meal in short periods (29 to 45 days) both the smallest and greatest gains, 1.269 and 1.776 lbs. per head per day, were noted with lots fed corn meal and linseed meal 5:1. The grain required per pound of gain was least with one of these lots being 3.85 lbs. and greatest, 4.75 lbs., with a lot fed corn meal and wheat middlings 2:1.

"The rations of linseed oil meal and corn meal in proportion of 1:5 were eaten in larger quantity than any other feeds tested and made more pork with smaller expenditure of feed than any other ration involved."

The estimated cost of pork made from the oil-meal rations averaged 11.3 per cent less than from the rations of corn meal and wheat middlings.

"Of the three corn products, gluten feed, gluten meal and germ oil meal, the first mentioned seems to be more useful than the others when fed with corn and linseed oil meal. None of them, however, in this combination are as useful as linseed oil meal by itself.

"Gluten meal is richer than gluten feed, differing from it only in lacking the corn bran with which it is ground to make the latter, but it does not seem to be as useful a supplement to corn and oil meal. The ration containing it was not so well relished and was not so efficient. It is possible that the usual recommendation that gluten meal be soaked before feeding to hogs would, if followed, have rendered it more valuable in comparison with gluten feed than it was in this experiment where it was fed immediately after wetting."

In 3 of the tests a mixture of corn meal and cotton-seed meal 8:1 was fed for 51 days. Cotton-seed meal fresh from the factory was fermented at living room temperature for 24 hours previous to feeding, sour milk being used as a starter. It was hoped that this fermentation would render the meal less toxic than it is reputed to be. The cotton-seed meal ration was mixed to a thinner slop than the other rations as it has been claimed that this is a desirable practice. The average daily gain per pig was 0.966 lb. and the grain eaten per pound of gain 4.97 lbs. Three of the 15 pigs included in these tests died at the end of the feeding period. "The gains up to that time had been moderate in extent and cost. The hogs did not relish this feed. A change to the corn and linseed oil meal ration induced much greater consumption of grain, increased the gains in weight 39 per cent and reduced the grain requirement per pound of increase to the extent of 13.1 per cent."

When ear corn and linseed cake 6:1 were compared with corn meal and linseed cake 5:1, the average daily gain per pig on ear corn during the 61 days of the test was 1.004 lbs. and the grain eaten per pound of gain 6.65 lbs. Similar values for the corn meal ration were 1.291 lbs. and 6.05 lbs.

Corn meal and oil cake "fed dry and mixed produced gains in weight with 9 per cent less grain than did ear corn and oil cake fed separately, both dry. The gain in the corn meal lot was 28.6 per cent greater than in the ear corn lot. The hogs receiving ear corn would not eat more than one-sixth as much oil cake as corn (the cob figured out) when both were allowed ad libitum."

In the opinion of the author the severity of the weather had an unfavorable effect on the gains made. The subject is discussed and data summarized regarding the influence of temperature on gains, indicating "that extreme heat of summer and extreme cold of winter act alike to the extent that they both occasion large energy expenditure on the part of the animal, in one case to keep warm, in the other to keep cool; and in either case occasion a great reduction in the profit from feeding in the dry lot when compared with results obtained in spring and fall. These results, however, do not apply to the feeding of hogs on pasture."

The poultry industry in Tasmania, R. J. TERRY (*Agr. and Stock Dept. Tasmania, Bul. 7, pp. 15, figs. 4*).—Various questions connected with profitable poultry raising under local conditions are discussed and some experimental data on fattening poultry are briefly reported.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Profitable dairying, C. L. PECK (*New York: Orange Judd Co., 1906, pp. XII+174, figs. 34*).—This is offered as "a practical guide to successful dairy management," and consists of 23 chapters in which are discussed the physiology of milk secretion, dairy breeds, feeding cows, milking, care of milk, butter making, and similar topics.

Breed, individuality, and heredity in the production of milk, M. FISCHER (*Landw. Jahrb., 35 (1906), No. 3, pp. 333-379, pls. 3*).—A study was made of the yield and composition of the milk with particular reference to the casein of 12 cows representing 6 different breeds, and also of 10 cows selected from a large herd with a view to showing the influence of individual characteristics and heredity.

The milk of the mountain breeds including the Brown Swiss and Simmental showed a higher percentage of fat, casein, and solids-not-fat than that of the lowland breeds including the Oldenburg, East Fresian, Angler, and Wilstermarsch. The average annual yield of the latter group, however, was greater, making the annual yield of fat and casein of the 2 groups practically the same. In producing milk for cheese making the Brown Swiss breed is considered especially valuable as compared with the other breeds mentioned.

Within the same breed the author finds in casein production as in fat production marked individual variations. The transmission of individual characteristics is discussed at some length.

A test of a fly repellent, C. H. ECKLES (*Missouri Sta. Bul. 68, pp. 35-39*).—The entire dairy herd was sprayed with a fly repellent each morning during alternate periods of 2 weeks each. The test was continued during the entire summer of 1903 and for 6 weeks in the summer of 1904. The yields of milk and fat during the periods when sprayed and when not sprayed are tabulated and show no important effects either upon the yield of milk or fat due to the use of the fly repellent. When applied every morning the material used was fairly effective in protecting the cows from flies, but the claim made that the material will protect cows if applied at intervals of several days is considered erroneous.

Milking machines, P. G. WICKEN (*Jour. Dept. Agr. West. Aust., 13 (1906), No. 4, pp. 301-303, pls. 2*).—This is a summary of a report on the use of milking machines in Western Australia, the author concluding that the Lawrence-Kennedy-Gillies machine is now beyond the experimental stage and is working in hundreds of places daily giving practical results.

The composition of milk, H. D. RICHMOND (*Analyst, 31 (1906), No. 363, pp. 176-180*).—The average composition of 14,828 samples of milk analyzed during 1905

was as follows: Specific gravity, 1.0323; total solids, 12.70 per cent; fat, 3.73 per cent; and solids-not-fat, 8.97 per cent. The average fat content of the morning milk was 3.54 per cent and of the evening milk 3.91 per cent.

Analyses are also reported of 1 sample each of human milk, ass's milk, adulterated cream, a butter adulterant, and a new preservative. The butter adulterant consisted mainly of casein and the new preservative was acid potassium fluorid.

The milk supply of Boston, New York, and Philadelphia, G. M. WHITAKER (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 81, pp. 62, figs. 4*).—In this account of the milk supply of each of the cities mentioned information is given on the magnitude of the business, source of the milk, means of transportation, freight rates, handling the milk in the city, sanitary regulations, and similar topics. Maps are given showing the source of the milk supply of each of the cities.

On the influence of milk control upon the composition of milk in Gratz, K. HELLE (*Arch. Hyg., 56 (1906), No. 1-2, pp. 205-207*).—Under the influence of milk control the average fat content of the market milk of this city increased from 2.6 per cent in 1898 to 3.54 per cent in 1905.

The rapidity of the absorption of odors by milk, F. BORDAS and TOUPLAIN (*Compt. Rend. Acad. Sci. [Paris], 142 (1906), No. 22, pp. 1204, 1205*).—Milk exposed for several minutes in an atmosphere containing formaldehyde in the proportion of 1:100,000 showed clearly a reaction for this substance. The fresher the milk the more rapid was the absorption.

Contribution to the study of the bacterial content of milk and of the udder, R. D'HEIL (*Arb. Hyg. Inst. K. Tierärztl. Hochschule Berlin, 1906, No. 7; abs. in Rev. Gén. Lait, 5 (1906), No. 13, p. 306*).—The author finds bacteria regularly present in the milk cistern and ducts and concludes that they gain entrance through the orifice of the teat. Glandular tissue which contains only a small number of bacteria is believed to possess considerable bactericidal power. The higher bacterial content of machine-drawn milk is considered due to the difficulty of cleansing milking machines.

The contamination of milk at the dairy, A. H. STEWART (*Amer. Med., n. ser., 1 (1906), No. 1, pp. 17-21, figs. 9*).—Six experiments are reported which show in a striking manner the value of sterile covered milk pails in lessening the bacterial contamination of milk.

On the frequency of streptococci in milk, M. KAISER (*Arch. Hyg., 56 (1906), No. 1-2, pp. 51-89*).—Streptococci were found in 76.6 per cent of 30 samples of milk collected in Gratz and vicinity from November, 1904, to July, 1905. The cultural tests are reported in detail.

On the streptococci of milk, P. T. MÜLLER (*Arch. Hyg., 56 (1906), No. 1-2, pp. 90-107*).—Twenty-one cultures of streptococci isolated from pathological products and 22 from milk samples were studied as regards their power of coagulating milk, hemolytic properties, and behavior toward agglutinating serum.

It was found that nearly all of the milk streptococci curdled milk at the end of 24 hours, while very few of the pathogenic streptococci curdled the samples even at the end of 48 hours. All samples in both series, however, were curdled in 72 hours. The more rapid production of acid by the milk streptococci, however, is not considered as showing any specific difference between the two groups of organisms.

In studying the hemolytic power of the various organisms the cultures were divided into 2 series, the first containing those recently isolated, and the second those grown for some weeks in the laboratory. Of the 13 pathogenic streptococci in the first series 7 showed hemolytic properties, and of 10 in the second series 4 were distinctly and 1 slightly hemolytic. Of 10 milk streptococci in each series, 5 in the first and 3 in the second possessed hemolytic properties. The results, therefore, showed no striking difference between the pathological and milk streptococci as regards hemolysis.

In the agglutination tests 7 out of 11 milk streptococci reacted with an immune serum in a dilution of 1:10, while 2 reacted in a dilution of 1:400. Eight out of 9 streptococci of the pathogenic group gave a positive reaction in a dilution of 1:10 and 4 in a dilution of 1:400. The results are interpreted as showing a close relationship between some of the milk streptococci and pathogenic forms, and this was emphasized by the fact that the milk streptococci which reacted with immune serum in high dilutions were the forms which produced hemolysins.

The author, therefore, concludes from the results of his own and other investigations, which are cited, that there can no longer be any doubt that pathogenic streptococci are present in milk. How frequently these are present is a question yet to be answered.

The reduction test as a means of determining the freshness of milk, P. T. Müller (*Arch. Hyg., 56 (1906), No. 1-2, pp. 108-204, figs. 5*).—In making this test in laboratory work the author uses 4 test tubes, in one of which is put 2 cc. of whole milk and in the others equal quantities of milk diluted with water in the proportion 1:2, 1:4, and 1:8. To each tube is added 0.2 cc. of a 0.2 per cent solution of methylene blue, and the liquid after mixing is covered with a layer of liquid paraffin about 2 cm. in thickness. The samples are then placed in a thermostat at 37° C. and the time required for the reduction of the methylene blue in the whole milk is observed.

This test was applied to numerous samples of market milk showing different degrees of acidity; mixtures of fresh and sour milk; dirty milk; milk to which soda, boric acid, salicylic acid, formaldehyde, and hydrogen peroxid had been added; and heated milk.

For fresh milk obtained in a cleanly manner the time required for the reduction of the methylene blue was 10 or more hours, and for milk delivered by producers directly to consumers during cold weather 6½ to 9 hours. The reduction test of milk obtained from small dealers during the forenoons was 5 to 6 hours during cold weather and 1 to 2¾ hours during warm weather, while that of the samples obtained during the afternoons was ¾ to 3 hours during cold weather and ⅓ to 1 hour during warm weather. Milk kept at a high temperature showed a shorter reducing period than milk kept at a low temperature.

Curdled milk reduced the methylene blue in a few minutes. The addition of small quantities of sour milk and also of manure to fresh milk shortened greatly the reducing period. The neutralization of milk with soda was without influence on its reducing properties, but the addition of soda to milk poor in bacteria lessened the time required for reduction until sufficient acid was produced to render the milk again neutral or acid.

The addition of preservatives such as boric acid, salicylic acid, and formaldehyde lessened or destroyed the reducing power of the milk. Milk heated for 15 to 30 minutes at 100° C. showed only a small reducing power, which, however, gradually increased the longer it was kept.

The author describes a modified form of the laboratory method which he considers suitable for household use in determining the freshness of milk. When reduction does not occur at the end of 1 hour the milk is considered suitable for infant feeding.

The testing of market milk, A. Lam (*Chem. Ztg., 30 (1906), No. 39, p. 467*).—This is an abstract of a paper presented before the Sixth International Congress of Applied Chemistry.

In testing market milk in regard to its sanitary condition the author determines what he calls the catalase number. Ten cc. of milk is treated with 5 cc. of a 1-per cent solution of hydrogen peroxid and allowed to stand for 24 hours at a temperature of 22 to 35° C. The number of cubic centimeters of oxygen gas liberated is designated the catalase number. For fresh pure milk this varies between 0.3 and 1. In cases of mastitis or tuberculosis of the udder this number is found to be increased. Milk showing a catalase number of over 3 is considered unfit for use.

The author has also found polarization of the milk serum of value for this purpose. While the normal index of refraction lies between 5 and 5.5, it was found to be 1.2, 1, and 0.73 in the case of diseased animals. The freezing point, however, remained constant.

The care of composite milk samples, I. C. WELD (*New Hampshire Sta. Bul. 126, pp. 181–184, figs. 5*).—Brief notes are given on the taking of composite milk samples and on preserving them with formalin, potassium bichromate, or corrosive sublimate.

On the combination of lactic acid with casein in lactic fermentation, C. RICHET (*Compt. Rend. Soc. Biol.* [*Paris*], *60* (*1906*), *No. 14, pp. 650, 651*).—When milk was allowed to coagulate spontaneously the curd was found to fix about 5 times the amount of lactic acid contained in the same volume of whey.

A test of tin can separators, C. H. ECKLES (*Missouri Sta. Bul. 68, pp. 23–34, figs. 4*).—Tests were made of 3 forms of so-called separators which consist of 2 cans one within the other. The milk is placed in the inner can and cold water in the outer can surrounding the milk.

The average results of 42 trials with these cans showed that the skim milk contained 1.39 per cent of fat, equivalent to a loss of 22.56 per cent of the fat. The 3 patented cans were compared with shallow pans, a dilution can, the centrifugal separator, and a homemade can. Under the conditions of the comparison the shallow pans gave better results than either the dilution or double cans. The homemade can costing $1.50 gave equally good results as the patented cans costing from $6 to $10.

Creamery problems, C. L. BEACH (*Connecticut Storrs Sta. Bul. 40, pp. 38–47*).—Of 1,362 patrons of 18 creameries in 1903, 256, or 19 per cent, were using centrifugal separators, while the remainder were using the Cooley system of cream raising. Comparative tests were made of these 2 methods.

The average of 13 samples of skim milk by the Cooley system showed the presence of 0.27 per cent of fat, and the average of 36 samples of separator skim milk showed the presence of 0.056 per cent. It is estimated that with a herd of 10 cows the hand separator effects a saving of $25.48. Five types of centrifugal separators were compared, the fat content of the skim milk ranging from 0.038 to 0.076, which difference for a herd of 28 cows is estimated as equivalent to $7.95 for one year.

The fat content of 10 samples of skim milk was determined by gravimetric analysis and by the Babcock test, using 17.6 cc. and 25 cc. of acid. The average results for the 3 methods were, respectively, 0.144, 0.046, and 0.063 per cent. Even with the excess of acid the Babcock readings were much lower than the gravimetric determinations.

Readings of Babcock tests were made at temperatures of 130 and 180° F., the average difference on 10 samples being 0.42 per cent. This emphasizes the importance of making the readings at a uniform temperature.

Variations in the weight of 18 cc. of cream containing different percentages of fat are given in tabular form to show the importance of weighing samples.

In 14 experiments a starter made from a pure culture was compared with a skim milk starter. The average score of the butter from the 14 churnings when the pure culture starters were used was 94 and of the butter from the churnings ripened with skim milk starters 94.1. A table shows the bacterial content of 12 samples of butter, of the cream from which the butter was made, and of the starter used in ripening the cream.

Creamery cold storage, J. A. RUDDICK (*Canada Dept. Agr., Dairy Comr. Branch Bul. 10, pp. 14, pls. 2*).—This furnishes information on the subject of creamery cold storage and embodies the results of recent experiments conducted for the purpose of testing various materials used for the purpose of insulation. Specifications are given

for the construction of creamery refrigerators on both the air circulation and cylinder systems.

The manufacture of whey butter at Swiss cheese factories, E. H. FARRINGTON (*Wisconsin Sta. Bul. 132, pp. 32, figs. 17*).—This bulletin, which is published in both English and German, contains descriptions of the methods employed in making whey butter in Swiss cheese factories in Wisconsin, with suggestions for the improvement of these methods.

The cold process of skimming the whey is considered not only wasteful but unsatisfactory on account of the extremely sour condition in which the whey is returned to the farmers, and also because the cream so obtained is not suitable for the manufacture of good butter. It is believed that this method should be abandoned. The hot process is considered much superior to cold skimming in that much more fat is recovered and the cream is in a sweet condition, making it possible to produce butter of good flavor.

About 2 years ago some experiments were made at the University of Wisconsin dairy school in skimming whey with a centrifugal power separator, and since then this method has been tried on a practical scale in a number of factories. According to the author's observations centrifugal separation is much superior to the other methods. The separator removes nearly all of the fat and permits the making of butter equal in quality and water content to creamery butter. The objections made to installing separators in cheese factories are their cost and the expense for power. Results have shown, however, that with improved methods of skimming and churning the surplus whey butter may more than pay for the additional cost.

In addition to the separator there is needed in the Swiss cheese factories, according to the author, a cream vat of some sort in which the whey cream may be ripened and cooled before churning and improved methods of working the butter.

The suggestions made for improving whey butter cover skimming the whey, ripening the cream, making and using a starter, churning the cream, working the butter, and other topics.

Some facts about moisture and its effects on butter, G. L. McKAY (*Hoard's Dairyman, 37 (1906), No. 16, pp. 432, 433*).—In discussing this subject the author gives data obtained at the Iowa station and observations made abroad.

It is not believed that the poor keeping quality of butter is due to an excess of moisture so much as to unsanitary methods pursued and the use of overripe cream. The author considers that "there is no danger of any maker incorporating too much water who churns his butter in a granular condition and does not resort to abnormal methods, such as churning at high temperatures, washing with warm water, overchurning, or working the butter in water."

On the composition of Dutch butter made in the creameries placed under State control, T. VAN SILLEVOLDT (*Gen. Dir. Agr. Min. Agr., Indus. and Trade [Netherlands], [Circ.], 1905, No. 5, pp. 31; 1906, Jan., Feb., Mar., Apr., pp. 4 each*).—Of 4,340 samples of butter analyzed during October, November, and December, 1905, 78 showed a lower Reichert-Meissl number than 24. The analytical results are hereafter to be published monthly, with a special report every 6 months on the samples showing low Reichert-Meissl numbers.

Bacteriological examinations of the butter of Stuttgart, A. REITZ (*Arch. Hyg., 57 (1906), No. 1, pp. 1-28, figs. 5*).—This is a detailed report of the inoculation experiments with guinea pigs made to determine the presence of tubercle bacilli in butter, previously noted from another source (E. S. R., 17, p. 1109). Tubercle bacilli were present in 8.5 per cent of the samples.

Fungi in cheese ripening: Camembert and Roquefort, C. THOM (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 82, pp. 39, figs. 3*).—This reports in detail the mycological studies referred to in the previous bulletin (E. S. R., 17, p. 79) on the manufacture of Camembert cheese in the United States.

In the manufacture of soft cheese of the Camembert type the curd is rendered acid by the action of lactic-acid bacteria, and later alkaline by the growth of various species of fungi which, through the production of enzyms, break down the curd to a greater or less extent.

"The Camembert Penicillium (*P. camemberti*) is the only species so far studied with which the particular appearance and texture sought in the ripened Camembert can be produced from curd soured by lactic bacteria without producing any objectionable flavor.

"*Oidium lactis* is always found upon Camembert cheese and so closely associated with the presence of the flavor as to indicate its agency in flavor production, though only circumstantial proof of such function has been possible thus far. The participation of bacteria in flavor production is not excluded by these results.

"Other species of fungi have been shown to produce variations in this flavor such as have been often found in certain market cheeses."

The Roquefort Penicillium (*P. roqueforti*) is the only fungus found necessary to produce the typical flavor of Roquefort cheese. This mold has also been found in imported Stilton, Gorgonzola, and Brinse cheese as well as in the Roquefort.

Oidium lactis is the only fungus which has been found regularly upon Limburger, American Brie, Isigny, and related types of cheese.

Technical descriptions are given of the 2 forms of Penicillium under the new names *P. camemberti* and *P. roqueforti* and of *Oidium lactis*.

A new method of making dry red wine, F. T. Bioletti (*California Sta. Bul. 177, pp. 36, figs. 14*).—Wine-making experiments during the year have abundantly verified, according to the author, the claims made for the method given in Bulletin 167 of the station (E. S. R., 17, p. 183).

"The most important conclusion to be drawn from these experiments is that sound dry wine of fair quality can be produced in the upper San Joaquin Valley and similar regions from the varieties of grapes growing there, simply by ordinary attention to cleanliness, the sterilization of cooperage, and more than ordinary attention to the control of temperature.

"For white wines a thorough preliminary defecation of the must by means of sulphur fumes and the use of pure yeast or yeast starters is advisable.

"For red wines some form of cooling machine is essential, and the temperature of the fermenting wine should never exceed 95° F., and if possible should be kept below 92° F. This can be easily and perfectly done by means of the cooling machine described in Bulletin No. 174 (E. S. R., 17, p. 1110).

"The grapes both for white and red wines should be thoroughly ripe. Ripeness must be determined by the flavor and appearance of the grapes more than by the amount of sugar they contain. We can not hope to get the best results from imperfectly ripe grapes even if they contain 22 per cent of sugar. Some varieties in the climate of the San Joaquin Valley are not perfectly mature for wine-making purposes until they contain 25 per cent of sugar or more. Better results are to be obtained by diluting and, if necessary, adding tartaric or citric acid to over-ripe grapes in this region than by attempting to make wine from under-ripe grapes which have not developed the color, body, and flavor necessary for the production of good wine."

The cost of applying this method on a large scale is yet to be ascertained, and with this in view a plan is given of a cellar suitable for working 50 tons of red grapes per day along with an outline of the method of operation.

The artificial ripening of grapes, L. Mathieu (*Rev. Vit., 25 (1906), No. 640, pp. 313–316*).—The results are given of an experiment in which wine was made from grapes partially dried in an evaporator. The work shows that it is possible to partially evaporate grapes in order to concentrate the must without any injurious effects or cooked taste to the wine. The process favors the production of a wine of superior quality.

VETERINARY MEDICINE.

Proceedings of the American Veterinary Medical Association (*Proc. Amer. Vet. Med. Assoc., 42 (1905), pp. 506, pls. 20*).—This volume contains an account of the meeting of the forty-second annual convention of the American Veterinary Medical Association, held in Cleveland, Ohio, August 15–18, 1905.

As usual, in the proceedings lists are given of the officers, committees, resident secretaries, and honorary and active members of the society. The address of welcome was given by the mayor of Cleveland, T. L. Johnson, and was responded to by R. R. Bell. The president's address, by M. E. Knowles, contained references to various veterinary matters, particularly to the cooperation of veterinarians and physicians and the importance of the veterinarian in the promotion of general sanitation.

In the reports of resident State secretaries attention is called to the condition of health in domesticated animals in the various States and Territories. In Arizona and New Mexico, particular attention was given during the year to sheep scab; in Colorado to cattle mange, loco weed, and bovine tuberculosis; in Connecticut, Cuba, and Porto Rico, to the legislative control of animal diseases; in Maine, to tuberculosis and glanders; in Maryland, to anthrax and forage poisoning; in Michigan, to rabies; in Minnesota, to hemorrhagic septicemia and swamp fever; in Mississippi, to anthrax and Texas fever; in Nebraska, to various parasitic diseases; in Ohio, to tuberculosis and swine plague; in Ontario, to actinobacillosis and hog cholera; in Pennsylvania, to legislation regarding experimental veterinary work; in the Philippines, to surra, rinderpest, and foot-and-mouth disease; in Tennessee, to glanders and influenza; in Texas, to Texas fever and cattle mange; in Vermont, to anthrax and glanders; and in Wisconsin, to the present status of the veterinary practitioner.

The Report of the Committee on Intelligence and Education, by C. J. Marshall et al., contains a general review of matters of interest to veterinarians, a digest of recent veterinary literature, and a detailed account of the quality of instruction and the curricula in various veterinary schools in this country.

In the report of the Committee on Diseases, by C. H. Higgins et al., attention is devoted to methods of keeping the clinical history of cases, the need of more veterinary research work, and the discussion of rabies, *Bacillus necrophorus*, roup in chickens, and the State control of tuberculosis. The present status of the movement for securing legislation regarding army veterinarians was presented by a committee consisting of W. H. Lowe et al.

An unusual number of papers were read at the various meetings of the convention and are printed in the proceedings. It is impossible to refer to these except in the briefest manner. The Artificial Immunization of Cattle Against Tuberculosis was discussed by L. Pearson and S. H. Gilliland. The authors report considerable success in the use of various vaccinating methods and believe that these methods promise to become much more effective. Papers were also presented on The Pathology of Tuberculosis, by C. Schulin, and by R. H. Harrison on Unusual Lesions of Tuberculosis Found in Abattoir Inspection. The method of controlling glanders adopted by a French firm which employs a large number of horses was discussed in a paper by E. Lavalard. The method consists in the general use of mallein, furnishing as favorable conditions as possible for suspected horses in quarantine, and the exercise of great care in introducing strange horses into a healthy herd.

The Spavin Group of Lamenesses was discussed by W. L. Williams et al. This account is one of the most important thus far published on the general subject of spavin and enters, in great detail, into the pathology, peculiar forms, etiology, and treatment of the disease by different methods.

Mention should also be made of the following papers: The Clinical Examination of the Blood of the Dog, by S. H. Burnett and J. Traum; Cultivation of *Trypanosoma equiperdum*, by J. R. Mohler; Twenty-seven Years' Experience in Veterinary Practice, by J. V. Newton; Accidents and Sequelæ of Surgical Operations, by L. A. Merillat; Indications for Neurectomies of the Pelvic Limb of the Horse, by R. C. Moore; The Profession and the Advancement of Science, by D. A. Hughes; Stable Ventilation, by M. H. Reynolds; The Status of Therapeutics, by P. A. Fish; A Review and Criticism of the Eighth Decennial Revision of the Pharmacopœia of the United States, by E. L. Quitman; Hydrothorax in the Horse, by G. B. Jones; and A New Treatment for Gastro-Intestinal Catarrh of Milk-Fed Calves, by L. A. Klein.

Annual report of the State board of live stock commissioners of Ohio, P. FISCHER (*Ann. Rpt. Bd. Live Stock Comrs. Ohio, 4 (1905), pp. 71, figs. 14*).—The diseases which have occurred in Ohio to an extent which attracted the attention of the live stock board during the past 4 years included the most important diseases of horses, cattle, sheep, hogs, cats, and fowls.

The work of the board of the live stock commissioners has extended in many directions, until at present it is considered that the services of additional veterinarians are needed. As usual in these reports maps are given showing the location of anthrax, actinomycosis, foot-rot, glanders, hog cholera, swine plague, keratitis, nodular disease, rabies, mange in horses, tuberculosis, and Texas fever. In the case of each one of these diseases a brief account is presented of the work of the State veterinarian and his assistants in controlling the outbreaks.

In an appendix to the report copies are given of laws relating to live stock and the duties of the board of live stock commissioners of Ohio.

Abstracts of work done in the laboratory of veterinary physiology and pharmacology, III, P. A. FISH ET AL. (*Ithaca: N. Y. State Vet. Col., 1906, pp. 44*).—An account is presented of a case of urethral calculus in the dog (pp. 3–8), arecolin hydrobromate and its action upon dogs and cats (pp. 9–13), the effects of sulphurous acid upon peptic and tryptic digestion (pp. 14–21), ergot as an abortifacient (pp. 22–29), the status of therapeutics (pp. 30–34), the structure and function of the digestive tract of the chicken (pp. 35–42), and the effect of sulphurous acid upon the urinary constituents (pp. 43, 44).

In experiments with ergot in which cats were used, it was found that doses of this drug would produce abortion within 24 hours. In some cases the young were killed, while in others they seemed not to be affected. It is concluded, therefore, that ergot exercises an abortifacient action of considerable power. Attention is called to the present status of theraputics as a profitable subject of study for veterinarians. New drugs are constantly being put on the market, and from the great number thus offered for use the veterinarian must select, as a result of experiment, those which really give promise of good results. Some of the new remedies are superior to the old ones used for specific purposes, while others are no better or quite inferior.

The Bang method of controlling tuberculosis with an illustration of its application, H. A. HARDING, G. A. SMITH, and V. A. MOORE (*New York State Sta. Bul. 277, pp. 81–109*).—A general account is presented of the nature of tuberculosis, together with a description of the Bang method of controlling the disease and the use of tuberculin.

In December, 1900, one animal in the station herd was found to be tuberculous and on this account the tuberculin test was given to the whole herd. As a result of the test a reaction was obtained with 8 cows and 7 young cattle in a total of 28. These animals were kept under observation, and in 1901 the Bang system was put in operation for the purpose of determining its value under the conditions which prevailed in the station herd.

The method was applied to a total of 30 animals, 13 of which were healthy and 17 tuberculous. During the 4 years of the test this herd produced 23 heifer calves,

one-half of them coming from the tuberculous animals. The calves obtained from the tuberculous cows were not allowed to suck their mothers nor to drink tuberculous milk until after it had been pasteurized at a temperature of 185° F. The record of the tuberculous part of the herd is given in a tabular form and notes are also presented on autopsies on diseased animals and an examination of the meat of tuberculous animals killed for beef.

A healthy herd from a tuberculous herd, F. H. HALL, H. A. HARDING, G. A. SMITH, and V. A. MOORE (*New York State Sta. Bul. 277, popular ed., pp. 8, fig. 1*).—A popular summary of Bulletin 277, noted on page 1189.

Combating tuberculosis in farm animals, A. VAN LEEUWEN (*Tijdschr. Veeartsenijk., 33 (1906), No. 6, pp. 340–345*).—This is a controversial article in which the author takes the position that a governmental requirement of notification of all cases of tuberculosis in domesticated animals would work great hardship. It is frequently impossible for the owner to determine when an animal is affected with the disease, in fact the most experienced veterinarians sometimes have to make use of all means of diagnosis in order to determine the matter.

Distribution of tuberculosis in suspected and nonsuspected herds in Wisconsin, H. L. RUSSELL and E. G. HASTINGS (*Wisconsin Sta. Bul. 133, pp. 15, figs. 3*).—On account of the insidious nature of tuberculosis and also on account of the fact that the disease has been found very prevalent in certain dairy herds the present bulletin has been prepared for the purpose of furnishing a concise description of the tuberculin test and further data regarding the results obtained from this test and its reliability.

Brief summaries are presented of some of the previous work done by this station on tuberculosis, and recommendations are made regarding the disinfection of stables. For this purpose the authors recommend a whitewash made of fresh unslaked lime, and also saturated solution of copperas.

Are tubercle bacilli coughed up by cattle affected with pulmonary tuberculosis? J. A. KLAUNERS (*Tijdschr. Veeartsenijk., 33 (1906), No. 6, pp. 351–353*).—From statistics regarding the organs affected in cases of bovine tuberculosis it appears that the lungs were diseased in 40,306 cases among a total of 46,092. On the basis of these facts and the further fact of the frequent infection of the lymphatic glands of the throat and pharynx, the author justifies the conclusion that tuberculosis in cattle is very frequently contracted by inhalation and that, therefore, the tubercle bacilli which cause such infection probably come from other cows affected with the pulmonary form of the disease.

Serum vaccination against anthrax, G. GAZZANIGA (*Clin. Vet. [Milan], 29 (1906), No. 8, pp. 203–205*).—Brief notes are given on vaccination for the purpose of preventing anthrax by the method which requires the use of two vaccines. This method has given satisfactory results in the author's hands.

Blackleg, W. H. DALRYMPLE (*Louisiana Stas. Bul. 85, pp. 7, fig. 1*).—Inquiries are frequently received at the station regarding the nature of blackleg and suitable treatment for this disease. It is suggested that probably many young scrub cattle of little value die of blackleg from year to year without any investigation of the cause of the disease. This fact may account for the persistence of the disease in certain localities. Notes are given on the cause, symptoms, treatment, and preventive vaccination for blackleg.

Vaccination against blackleg, K. R. KUIPERS (*Tijdschr. Veeartsenijk., 33 (1906), No. 6, pp. 345–351*).—Various methods were tried in vaccinating calves against blackleg. The author used vaccine thread, dried vaccine, and material in solution. The best results were obtained from the last-named method. Brief notes are given on the pathological anatomy of blackleg based on a number of autopsies.

Texas fever with methods for its prevention, J. R. MOHLER (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 78, pp. 48, pl. 1, figs. 3*).—The author presents a valuable

summary of information relating to the nature of Texas fever and the practical means of its eradication.

The subject-matter includes a definition of the disease; notes on its history and distribution; etiology; life history of the cattle tick and its agency in distributing Texas fever; means of distinguishing between this tick and other species of ticks; the loss caused by ticks aside from their agency in carrying Texas fever; symptoms, course, and termination of Texas fever; and treatment and prevention of the disease. Definite and practicable plans are presented for the arrangement of farms so that cattle may be freed from ticks and the ticks ultimately eradicated by the system of feed lots and pasture rotation. The method of immunization by means of the blood of recovered cattle is also described.

Vaccination against foot-and-mouth disease, N. L. Buonsanti (*Clin. Vet.* [*Milan*], *29* (*1906*), *No. 6, pp. 145–148*).—Numerous experiments have been carried out in vaccinating cattle against foot-and-mouth disease by means of a mixture of 0.03 cc. of virulent lymph and 0.5 cc. of bovine serum. For vaccinating hogs and sheep the author has used a concentrated serum from a horse previously inoculated with the virus. The results thus far obtained are promising.

The treatment of epizootic abortion, E. Thierry (*Jour. Agr. Prat., n. ser., 11* (*1906*), *No. 7, pp. 208, 209*).—A number of investigators have found that good results may be obtained from the use of antiseptic solutions, such as the use of corrosive sublimate, 1:1,000 parts in water, and a solution of iodin and iodid of potash. An internal prophylactic treatment, with doses of 5 to 6 drams of iodid of potash, has also given satisfactory results.

The poisoning of cattle by tobacco decoction, F. Peuch (*Jour. Méd. Vét. et Zootech., 57* (*1906*), *Feb., pp. 78, 79*).—Two heifers which had become greatly infested with fleas were treated by the owner with tobacco decoction as obtained from the manufacturer and diluted with an equal amount of water. Within a few hours serious symptoms of poisoning occurred, the animals being unable to rise and in a state of extreme coma. Considerable irritation of the skin was also produced. Recovery took place on the following day.

Attention is called by the author to the fact that tobacco decoction, diluted with 10 parts of water, is effective in such cases and ordinarily does not produce poisonous effects.

Vaccination for hog cholera, L. Brusasco (*Gior. R. Soc. ed Accad. Vet. Ital., 55* (*1906*), *No. 6, pp. 123–125*).—References are made to some of the more important publications on this subject and a table is given showing the results of vaccination against hog cholera during 1905. From this table it appears that the percentage of mortality in nonvaccinated hogs was 79.6, while in vaccinated animals it was 17.4.

Combating swine plague, Foth (*Berlin. Tierärztl. Wchnschr., 1906, No. 7, pp. 115–123*).—From the standpoint of the veterinary police, swine plague includes hog cholera as well as swine plague proper.

Although these diseases frequently occur simultaneously in the same animal, the official veterinary police must depend largely upon the clinical symptoms and the infectiousness of the disease in reaching a diagnosis. The persistent spread of swine plague is attributed to its already wide distribution, the chronic course of many cases, the aversion to strict quarantine, traffic in live pigs, too early period of weaning pigs, neglect of hygienic precautions, and the extensive use of improved breeds, some of which are less resistant than grade hogs.

Antidotes for poisoning by Gastrolobium calycinum, E. A. Mann (*Jour. Dept. Agr. West. Aust., 13* (*1906*), *No. 1, pp. 50, 51*).—Feeding experiments were carried out with this plant in the case of sheep in order to test various antidotes for the alkaloid poison in the plant. Permanganate of potash in acidulated water appeared to have no influence in checking the poisonous effects. Negative results were also

obtained with sodium bicarbonate. The action of tannic acid, however, when given as a drench in doses of ½ oz. appeared to be quite satisfactory.

Suggestions as to dipping sheep (*Jour. Bd. Agr.* [*London*], *12* (*1906*), *No. 11*, *pp. 678-681*).—Directions are given for cleaning dipping tanks and catching pens, mixing dips, trimming the wool, and related matters, together with notes on the proper time of dipping and on the repetition of the process.

Infectious broncho-pneumonia of lambs, E. THIERRY (*Jour. Agr. Prat., n. ser.*, *11* (*1906*), *No. 4*, *pp. 110-112*).—Opportunity was had for studying a rather serious outbreak of pleuro-pneumonia of lambs. As a result of this study it appears that the disease is of bacterial origin, although the micro-organism was not isolated. In controlling the disease the usual procedure in cases of infections is recommended, viz, isolation of diseased animals and thorough disinfection.

Further notes on the pathogenic organism of pneumonia and its biology, LORENZ (*Berlin. Tierärztl. Wchnschr.*, *1906*, *No. 9*, *pp. 145-147*, *figs. 3*).—As reported in previous articles by the author, an organism was found in the skin of horses affected with pneumonia several days after recovery.

This organism was obtained under the observation of the strictest rules of asepsis and proved to be a streptococcus when cultivated on artificial nutrient media. The streptococcus appears to develop from minute rods. This organism when used in inoculation reproduces the disease. The author believes as a result of a further study of this organism that it is really a plasmodium or sporozoan, which may be observed in various forms, such as spores and rods, which may unite to form streptococcus.

The demonstration of the organism of pneumonia in horses and its biology, LORENZ (*Berlin. Tierärztl. Wchnschr.*, *1906*, *No. 7*, *pp. 113-115*, *figs. 8*).—On account of the irregular manner in which an outbreak of pneumonia usually progresses in a herd of horses it has been assumed by many investigators that the organism of this disease must require an intermediate host, and in this connection flies have been suggested.

The author finds, however, that the organism persists for a long time in the subcutaneous tissue. It has been found in considerable numbers in such locations and kept in pure cultures. When the virus thus obtained was inoculated into rabbits, cocci were found in the blood 20 hours after inoculation. Since the organism described by the author appears to be the true cause of pneumonia, it is believed that a method of vaccination can now be readily devised which will protect animals against the disease.

Pleuro-pneumonia, MOUQUET (*Bul. Soc. Cent. Méd. Vét.*, *83* (*1906*), *No. 4*, *pp. 114-117*).—Notes are given on the symptoms of pleuro-pneumonia in horses in which septic edema occurred and an ammoniacal fermentation in the thoracic cavity. A study was made of the reaction and chemical properties of the serous fluid in the pleural cavity and the gases developed by the ammoniacal fermentation in this fluid were studied.

Experiments with contagious coryza, with especial reference to the immunization of rabbits against this disease, J. LUDWIG (*Monatsh. Prakt. Tierheilk.*, *17* (*1906*), *No. 7-8*, *pp. 289-321*).—The literature on this disease is critically reviewed in connection with a short bibliography.

It appears from experimental work carried out by the author that rabbits may be actively immunized against contagious coryza. A number of methods are successful in accomplishing this result, but the best seems to be found in the use of cultures killed by means of heat or by the use of iodin trichlorid. The active immunization may be brought about rapidly and may be carried to a high degree by repeated inoculations. The organism of contagious coryza is practically nonvirulent for rabbits when inoculated hypodermically, but in intraperitoneal injections it rapidly produces death. From the blood of rabbits thus immunized a serum may be obtained which will protect other animals from infection.

Experiments in protective inoculation against contagious coryza with dead streptococci, T. KITT (*Monatsh. Prakt. Tierheilk., 17 (1906), No. 7-8, pp. 363-367*).—The experiments reported in this paper were carried out on colts. It was found possible to immunize colts to a considerable extent by inoculating them with dead cultures of the streptococcus of contagious coryza. The method, however, has little to recommend it in actual practice, since in order to obtain a protective immunity 6 or 7 treatments must be given. Passive immunity which may be produced by means of injections of serum has only a short duration.

Kimberley disease in horses, R. E. WEIR ET AL. (*Jour. Dept. Agr. West. Aust., 12 (1905), No. 1, pp. 60-63*).—This disease has a course of variable duration and is characterized by symptoms of congestion and derangement of the brain.

It appears that the extraordinary mortality which occurs from attacks of this disease can not be attributed solely to one cause. The presence of parasites, however, particularly *Spiroptera megastoma*, may be looked upon as a predisposing cause, in connection with coarse forage and the ingestion of large quantities of green food. In treating the disease the author recommends antipyrin 3 times daily in doses of 1 dram together with a mixture containing ½ dram calomel and ½ oz. ginger.

A skin disease in horses affecting only the white markings, E. E. MARTIN (*Vet. Rec., 18 (1906), No. 922, pp. 628, 629*).—In Calcutta the author observed a number of cases of skin disease in Australian horses which had just been landed. The white parts only were affected and appeared as if blistered. The disease was attributed to an attack of insects, but the exact species was not known.

Osteomalacia in Tonquin, J. SOURREL (*Rev. Gén. Méd. Vét., 7 (1906), No. 77, pp. 233-248, figs. 3*).—During the years 1901-1904 the author had occasion to study osteomalacia in horses and mules in Tonquin.

It was found that the disease appears after a varying period following upon exposure or introduction to an affected region. The usual period ranges from 6 months to 2 years. Animals first appear lame and depressed, later malformations may appear particularly in the form of enlargements of the flat bones and short articular bones. Fractures of the long bones in the leg may occur at any time during the course of the disease. Ultimately the stage of extreme cachexia results, so that prognosis is always serious.

It was found that osteomalacia occurs in regions where there is plenty of lime in the soil and in the forage plants as shown by analysis. The absence of lime could, therefore, not have been the cause in the cases observed by the author. It is believed that the disease is of infectious origin, but the organism has not been isolated. Therapeutic treatment is not very successful, but some benefit was derived from the use of pilocarpin, purgatives, strychnin, and feeding green forage plants, for which purpose the author recommends the use of *Panicum æquinum*.

Use of artificial impregnator in horse breeding, L. L. LEWIS and W. L. ENGLISH (*Oklahoma Sta. Circ. 5, pp. 8, figs. 6*).—The importance and general use of the artificial impregnator by stockmen led the station to send out a circular letter of inquiry regarding the methods in common practice.

It appears that there are two forms of impregnator in general use, the straight and the curved. The latter is preferred, and may be used with or without a vaginal speculum. If a breeding bag is used on the stallion a speculum will be found unnecessary. Before service it may be well to close the neck of the uterus with a rubber plug. After service the plug is removed at once, a part of the semen injected into the uterus and the rest used to impregnate other mares. Before transferring the semen the syringe should be warmed in water at a temperature of 100° F. and the transfer should take place without delay.

Experiments in preserving semen in vials for a period of 3 hours or more showed that a temperature of 100-103° F. is less favorable to the vitality of the spermatozoa than 85° F. In Oklahoma the breeding bag is used by about two-thirds of those who

impregnate mares artificially. As was to be expected, better success attends the efforts of the breeder the longer he practices the method.

The effect of experimental epilepsy on poisoning by tetanus toxin, L. CESARI (*Compt. Rend. Soc. Biol.* [*Paris*], *60* (*1906*), *No. 8, pp. 397–399*).—It has been claimed by a few investigators that the effects of tetanus toxin may be somewhat overcome by passing an alternating electro-current through affected animals.

This was tested on guinea pigs by the author with the result that little benefit was found from the practice. Guinea pigs inoculated with tetanus toxin showed the epileptiform crisis of the disease during the passage of an alternating current in the same manner as shown by normal animals. The muscular contractions disappeared for a few minutes after the epileptiform crisis but soon recurred again. Animals treated in this manner lived little longer than the control animals.

Treatment of demodectic mange, CEDÉAC (*Jour. Méd. Vét. et Zootech.*, *57* (*1906*), *Feb., pp. 80–83*).—Attention is called to the undesirability of attempting to treat all forms of mange and parasitic skin diseases by similar lines of treatment. In some forms of mange caused by demodectes as well as phlegmenous dermatitis it is usually best to scarify the affected parts and apply tincture of iodin.

The bacillus of mouse typhoid and related forms, R. TROMMSDORF (*Arch. Hyg.*, *55* (*1906*), *No. 3, pp. 279–298*).—An attempt was made to determine the relationship and independence or identity of various bacteria related to the mouse typhoid bacillus.

In experiments along this line a series of agglutination tests were made, but it was found that agglutination is a very uncertain method of determining the identity or specific individuality of bacteria of this group. Apparently *Bacillus enteritidis* is distinct from the other bacteria of this group, while there are various groups under the paratyphoid bacillus as well as of the hog cholera bacillus. It was impossible by means of agglutination tests to differentiate between the mouse typhoid bacillus, hog cholera, paratyphoid, and meat-poisoning bacillus.

Attention is called to the fact that the bacilli which have been used for the destruction of mice as well as the hog cholera bacillus may be pathogenic for man. The author believes, however, that there is no justification for prohibiting the use of cultures of mouse typhoid bacillus in the destruction of field mice.

RURAL ENGINEERING.

Irrigation from Snake River, Idaho, H. G. RASCHBACHER (*U. S. Dept. Agr., Office Expt. Stas. Circ. 65, pp. 16*).—The territory covered by this circular extends from the Wyoming line to Salmon River, a distance of about 200 miles. In this area there is about 800,000 acres at present under ditch, and the proposed works will cover about 200,000 acres additional. Probably not more than half of this land is at present under cultivation, leaving a large area which is awaiting settlement.

This circular is devoted to the conditions which a new settler will meet in making a home in this section. With few unimportant exceptions, the settlers must secure rights from companies building ditches, there being little if any opportunity for securing rights directly from the streams. Most of the canals are built either under the Carey Act, under which the lands and water rights are disposed of on terms specified in contracts with the State, or under the reclamation act, which provides for the payment by the settler of the actual cost of the construction of the works, the lands being taken up under the homestead law, which requires the payment of land office fees only.

The prices of water rights under these various projects vary from $15 to $25 per acre. The expense which must be met by the new settler during the first year is estimated as follows, the full price of the water right being included in this estimate.

This, however, need not be paid during the first year, but may be distributed over a series of years.

First cost of the land and water right	$25.50
Fencing material	3.00
Labor:	
Grubbing sagebrush	3.50
Plowing	2.50
Seeding	.50
Leveling and marking	1.00
Ditching	2.00
Irrigating	2.00
Total cost per acre	40.00

The circular contains also the record of a number of crop experiments made at Twin Falls during the season of 1905.

Results of experiments on irrigated meadows, TACKE (*Mitt. Deut. Landw. Gesell., 21 (1906), No. 9, pp. 96–101*).—The experiments described were started in 1900 on meadow lands belonging to the agricultural improvement association of Bruchhausen-Syke-Thedinghausen.

Three types of soil were selected, a clayey loam meadow with a layer 25 to 30 cm. deep, rich in humus, a low moor, and a light sandy heath. These tracts were subdivided and given varying quantities of Thomas phosphate meal and kainit, with and without irrigation. The plats were irrigated by running and still water so as to compare the methods.

The average yield per acre without fertilizers on the first tract was increased 77 per cent by irrigating with running water, and 50 per cent by flooding in checks. With the application of a small amount of Thomas phosphate (150 kg. per hectare annually) there was a further increase of about 33 per cent, while additional quantities showed very small increases in the crop. Kainit alone showed no increase at all when applied at the rate of about 500 kg. per hectare annually, as the lands were not deficient in potassium salts. The other tracts show quite similar results.

In all cases the method of irrigating with moving water appears to give larger yields than the check-flooding method, averaging on the first tract 28 per cent greater, on the second 34 per cent, while on the third the advantage is even more marked. The running water is applied by ridging the land, and apparently not by furrows as in the United States. The author urges independent local experiments and cautions against accepting the data given as applicable under different conditions of soil and ground water.

Irrigated lands in Idaho (*The State of Idaho. Boise, 1905, pp. 59–62*).—A summary of irrigation statistics is presented, showing 3,600 miles of canals costing nearly $10,000,000 and covering over 2,000,000 acres, of which 840,000 are now under cultivation. The publication contains also articles on projects under the Carey Act and the Reclamation Act, and brief descriptions of irrigation systems by counties. The report is profusely illustrated.

[Irrigation in Wyoming] (*The State of Wyoming. 1905, pp. 54–79, pls. 6*).—Under the titles Public Lands and Irrigation Projects, State Lands, and How to Obtain a Right to Use Water in Wyoming, a review is given of Reclamation and Carey Act projects, ditches built and projected by private parties, and the laws relating to public lands and water rights.

Method and cost of constructing cement pipe in place, H. P. GILLETTE (*Engin. Rec., 53 (1906), No. 10, pp. 349, 350, figs. 2*).—The Ransome method of making continuous cement sewer pipe in place, which is described here, suggests the use of the same machine for drain pipes.

The device consists of a core 10 ft. long, with a sectional sheet-iron mold. The cement is rammed into place by hand, and the whole machine is moved gradually forward by winding up a cable by a lever and ratchet windlass. The actual cost of laying 8-in. pipe at Rochester, N. Y., was 6.6 cts. per foot, and for 12-in. pipe 10.25 cts. per foot, 300 to 400 ft. a day being laid with a crew of 7 or 8 men. While the pipes laid are said to be as tight as cement-jointed vitrified pipe, it would not be difficult to make them porous enough for drainage by using less cement or by providing openings.

An investigation of the ancient hydraulic works in Algeria, S. GSELL (*Paris: Govt., 1902, pp. 143, figs. 27*).—This report consists of descriptions of hydraulic works of Roman origin found in the various provinces of Algeria, written by local administrative officers, engineers, or army officers familiar with particular localities. There are described about 80 barrages, 30 reservoirs, 20 aqueducts, and a large number of smaller hydraulic works formerly used for irrigation or city water supplies.

Strainers for driven wells, D. H. MAURY (*Engin. News, 55 (1906), No. 10, pp. 260, 261, figs. 3*).—While fine strainers have been generally favored because they exclude fine sand, their capacity and durability are low.

The principle of the coarse strainer is that fine sand is freely admitted and may be pumped out, thus washing all the fine material from a zone surrounding the strainer and creating what is virtually a strainer of clean gravel having a large capacity, and since a certain initial velocity is required to start fine material toward the well, no silt will be drawn in when pumping any less water than the maximum capacity of the sand pump.

The author describes several well-strainers and the methods of perforating well casings after driving.

Mountain road construction in Idaho, E. B. DARLINGTON (*Engin. News, 55 (1906), No. 11, pp. 282, 283*).—The legislature of Idaho in 1905 authorized the expenditure of $50,000 for mountain roads, under the supervision of a State commission, the cost of new roads to be divided with the community benefited.

Over 100 miles of road have already been built or are nearing completion under this law. It is the policy of the commission to spend only $500 to $1,000 per mile, the roads being 8 to 12 feet wide, with a maximum grade of 12 per cent. Turnouts are built every half mile. All running streams are bridged, culverts are built in dry channels, and swampy places are corduroyed, all such structures to be 12 ft. wide. The roads are carefully located with a view to future improvements.

Road maintenance, R. A. MEEKER (*Engin. Rec., 53 (1906), No. 13, pp. 424, 425*).—An article written for the annual report of the New Jersey commissioner of public roads. The problem of maintenance is to reduce wear and replace worn material cheaply. Good drainage is essential; the wearing surface should be hard, and should be kept free from dust by sweeping or scraping, if the rains do not keep it washed away. General repairs should be made in fall and spring, and prompt minor repairs at all seasons. The use of the best stone only is recommended.

RURAL ECONOMICS.

Depreciation in agricultural values, P. CAZIOT (*Jour. Agr. Prat., n. ser., 11 (1906), No. 7, pp. 203-206*).—The value of agricultural land in France advanced during most of the nineteenth century, but since 1880 there has been a very great decrease, the decrease being as great as 70 or 80 per cent in some instances.

In general the land of the peasant proprietors has decreased to a greater extent than that of large estates. The causes given for this depreciation are that capital invested in land yields smaller returns than formerly, due to changes in agriculture which make the land a relatively less important agent in agricultural production. Intensive cultivation has given to operating capital a greater importance than it for-

merly had in agricultural operations. A second cause assigned is the decrease in rural population, which has resulted in a rise in wages.

Report on the operation of agricultural insurance societies, A. DE CÉRIS (*Jour. Agr. Prat., n. ser., 11 (1906), No. 14, pp. 421, 422*).—The official journal of April 1 contains a report on the operation of mutual agricultural insurance societies.

There has been in the last 9 years a very great increase in the number of these societies. There were 1,484 such societies in 1897, and 6,556 in 1906. They insure live stock against death, agricultural buildings against fire, crops against hail, and farmers against accident. The total amount of risks carried is 3,920,100 francs (about $785,000). The government supervises the organization of the new societies, paying special attention that the rates are high enough to insure payment of indemnities. It also supervises in a limited way the operation of societies and aids them in case of special need resulting from epidemics.

The government has encouraged so far as possible the federation of the smaller societies in order that they may have greater stability.

The loans of the Credit Foncier for agricultural enterprises, A. DE CÉRIS (*Jour. Agr. Prat., n. ser., 11 (1906), No. 14, p. 422*).—The commission appointed by the ministry of agriculture to make a study of the Credit Foncier and recommend modifications to make its loans more popular, has recommended that loans for drainage and other agricultural improvement shall be made easier, that loans should be extended to agricultural societies organized under the laws of 1865–1888, that interest should be lowered, and that the system of guaranteeing reimbursement be revised.

Meat in foreign markets, tariffs of fourteen importing nations, and countries of surplus (*U. S. Dept. Agr., Bur. Statis. Bul. 39, pp. 95*).—This bulletin contains a summary of information concerning the export trade in American meat, animal and packing-house products, the customs tariffs of 14 of the principal countries importing these animals and products, and the conditions of production of these commodities for export in 12 countries which are, or may become, competitors of the United States in this industry.

Meat animals and packing-house products imported into eleven principal countries, 1895–1904 (*U. S. Dept. Agr., Bur. Statis. Bul. 40, pp. 92*).—The value of the meat animals and packing-house products imported into 13 European countries and Cuba in 1904 was $506,715,512. Of the total amount sent to 11 of the countries included, the United States supplied 40.38 per cent.

Norway, Sweden, and Russia as markets for packing-house products (*U. S. Dept. Agr., Bur. Statis. Bul. 41, pp. 21*).—Information obtained from published official reports is summarized and classified.

The value of meat and other packing-house products imported into Norway in 1902–1904 had a value of $4,585,000, an increase of 29 per cent over 1895–1897. In Sweden the total value of these products imported was $4,227,000 in 1901-1903, and in Russia $4,337,000. In Sweden the increase since 1895–1897 was 62.3 per cent. "Russia being primarily an agricultural country with an enormous export of grain, and the Russian people consuming very small quantities of meats, the imports of meat animals and packing-house products are very small and do not show any strong tendency to increase."

Cotton production and statistics of cotton-seed products, 1905 (*Bur. of the Census [U. S.] Bul. 40, pp. 72, maps 2*).—This bulletin gives cotton statistics of the United States for the years 1902, 1903, 1904, and 1905; sketches the history of the production of cotton throughout the world; discusses the possible increase of cotton growing in the United States and other countries; and describes the products made from cotton seed, giving statistics.

The total production of cotton in the United States in 500-lb. bales was 10,827,168 in 1902, 10,045,615 in 1903, 13,679,954 in 1904, and 10,804,556 in 1905. The estimated value of the cotton crop was $501,897,134.65 in 1902, $660,549,230.82 in 1903,

$652,031,635.97 in 1904, and $632,298,322.57 in 1905. The conclusion reached regarding the production of cotton in foreign countries is that only in the remote future is there a prospect of any other country than the United States producing any large amount of cotton for export.

There has been a very large increase in the establishments making cotton-seed products since 1900, the number in that year being 369, and 715 in 1905. The value of the products increased from $19,335,947 in 1890 to $96,407,621 in 1905. These products include linters, hulls, and oil.

An introduction to the history of sugar as a commodity, ELLEN D. ELLIS (*Bryn Mawr Col. Monographs, 4 (1905), pp. 117*).—This monograph presents a study of the statics and dynamics of sugar and of the history of the substance as a commodity in various countries of the world. A list of over 100 references bearing on the subject from a practical, historical, geographical, and technical standpoint is given.

AGRICULTURAL EDUCATION.

Higher agricultural education, E. A. BRYAN (*Pullman, Wash.: Author, 1905, pp. 16*).—An address delivered before the Educational Congress of the Lewis and Clarke Exposition at Portland, Oreg., in which the aims of pure and applied science are set forth, and the development of agricultural education in the United States is outlined. Agricultural education is characterized as genuine, real education which can not do without the old instruments of education, but which "has added new and better instruments for the purpose of mind growth along certain directions, namely, that of the life which the student is to lead."

Educational agriculture, W. R. HART (*Peru, Nebr.: Author [1906], pp. 16*).—This is a discussion of the pedagogics of agriculture based on the premise that "before agriculture becomes entitled to a permanent place in the common school course it must withstand three tests: First, the test of usefulness; second, the test of mental discipline; third, the test of humanizing culture." The conclusion of the author is "that from whatever point of view the subject is approached, agriculture gives an affirmative answer to every test that can be applied to any subject, not excepting the richest, in any course of study."

How can a college of agriculture keep close to the ground? L. H. BAILEY (*Cornell Countryman, 3 (1906), No. 9, pp. 207, 208*).—The writer discusses means of bringing the people and the college closer together, and among other things suggests the sending of college students to approved farms to learn advanced farm practice, and the bringing of experienced farmers to the college to lecture and consult informally with students.

Proceedings of the nineteenth annual convention of the Association of American Agricultural Colleges and Experiment Stations held at Washington, D. C., November 14–16, 1905, edited by A. C. TRUE, W. H. BEAL, and H. C. WHITE (*U. S. Dept. Agr., Office Expt. Stas. Bul. 164, pp. 189, dgms. 2*).—An account of this convention has been given (E. S. R., 17, p. 321).

Proceedings of the tenth annual meeting of the American Association of Farmers' Institute Workers, edited by W. H. BEAL, J. HAMILTON, and G. C. CREELMAN (*U. S. Dept. Agr., Office Expt. Stas. Bul. 165, pp. 95*).—This is a detailed account of the proceedings of the meeting held at Washington, D. C., November 9–11, 1905.

Animal husbandry—four-year course, R. S. SHAW (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 142–144*).—This is a syllabus of a course in animal husbandry for graduates of a good high school, followed by a discussion of some features of the syllabus. Out of a total of 382 hours in the course 129½ hours are devoted to animal husbandry subjects, 30 hours to other agricultural subjects, and 25½ hours to hygiene, anatomy,

and veterinary science. The remainder of the time is taken up with English, mathematics, chemistry, botany, bacteriology, and drawing.

Course in cheese making for movable schools of agriculture, L. L. VAN SLYKE (*U. S. Dept. Agr., Office Expt. Stas. Bul. 166, pp. 63*).—This is the first of a series of courses designed to give more extended and specific instruction in agriculture outside of regularly organized schools than is now being given in the farmers' institutes. A brief statement concerning the plan for the movable schools is given in a prefatory note by the farmers' institute specialist of this Office. The course outlined in this bulletin consists of 14 lectures accompanied by 14 practicums. The bulletin also contains a list of apparatus needed in giving the course in cheese making and lists of references to the literature of the subject.

Syllabus for a four-year course in horticulture, U. P. HEDRICK (*Rpt. Mich. Acad. Sci., 7 (1905), p. 141*).—This is a syllabus of a course in horticulture suitable for graduates of a good high school. Required horticultural subjects occupy 65 out of a total of 420 hours, and this number may be increased to 110 hours by choosing senior electives in horticulture.

Teaching horticulture in high schools (*Agriculture* [*Nebr.*], *5 (1906), No. 2, pp. 2–6*).—Reasons for teaching horticulture and topics best suited for horticulture in high schools are given, also some items of necessary equipment, the most important of which is the school garden.

Topics in horticulture for common schools, U. P. HEDRICK (*Rpt. Mich. Acad. Sci., 7 (1905), p. 140*).—Horticultural topics suitable for common schools are arranged under the three heads propagation of plants, vegetable gardening, and pomology.

Outline for a brief course in agricultural economics, K. L. BUTTERFIELD (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 149, 150*).

Outline for a brief course in rural sociology, K. L. BUTTERFIELD (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 150, 151*).

Courses in some phases of rural economy. Outline for a course in farm management, F. W. CARD (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 148, 149*).

Teaching agricultural economics in the agricultural high schools, E. VLIEBERGH (*Rev. Gén. Agron., 14 (1905), Nos. 10–11, pp. 444–452*).—The author states that agricultural economics might be held to include studies of agricultural practice and also studies of economic, social, political, and legal conditions, but confines his discussion to the latter. A complete course of instruction is outlined. It includes property rights in land; rents; statistics; land taxes; tariff; public regulations; size of land holdings; succession; subdivision of holdings; credit; capital; labor; insurance; agricultural associations; teaching of agriculture; sanitary regulations, etc. It is recommended that class work be supplemented by the preparation of monographs, students studying conditions in their home communities and by seminar work.

How to determine what to teach in nature study, L. A. HATCH (*Nature-Study Rev., 2 (1906), No. 1, pp. 13–17*).—An argument in favor of teaching nature study with a clearly defined object in view. The writer holds that in planning a course in nature study "(1) A vital human relation should be found in all the work undertaken; (2) the course should contain within itself a rich content that is worth studying; (3) there should exist an intimate relation among the parts, holding the same together in such a manner that the work covered from year to year will be progressive and united."

Nature study in its practical bearings, J. P. STEWART (*Nature-Study Rev., 2 (1906), No. 2, pp. 55–66; reprinted from* [*Ill.*] *Normal School Quart.*).—A discussion of the reason for teaching nature study, its relation to agricultural teaching, what it should include, the principles that should guide in its organization and presentation, and the place where it should be taught. The writer's answer to the last question is "The all-important place for nature study is in the country school." The two prob-

lems for discussion in reaching the country school are (1) how to reach the teacher and (2) what to do in these schools, and how.

The relation of nature study to manual training, W. A. BALDWIN (*Nature-Study Rev., 2 (1906), No. 2, pp. 41-48, figs. 2*).—The writer discusses the relationships between these two subjects from 2 standpoints, that of the subject taught and that of the child. In the first case he shows that while nature study and manual training were once wide apart, they have been modified until they come very near together. Secondly, from the standpoint of the child, "the only true line of approach," he finds that it is difficult to distinguish between the two—that with the child at home on the farm most of nature study is also manual training, and vice versa.

Experiences in school gardening, J. B. DANDENO (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 156-160*).—An argument against the feasibility and desirability of conducting school gardens in rural schools based on the experience of the writer in growing plants and trees in a country school, and against teaching elementary agriculture in such schools based on the premise that "agriculture is purely and necessarily an art," and that in order to teach it the sciences botany, zoology, chemistry, physics, mineralogy, and geology would have to be taught.

The school garden at Bowesville, Canada, E. A. HOWES (*Nature-Study Rev., 2 (1906), No. 2, pp. 48-55, figs. 2, dgm. 1*).—An interesting account is given of a successful experiment "to determine what might be accomplished along the line of nature study by means of a school garden in a large ungraded rural school, under stable conditions, by a trained teacher supposed to be interested in the work." While the work in the lower grades did not differ materially from other school garden work, that in the upper grade consisted largely of cultural and spraying experiments with potatoes, this crop being one of the leading staples of the region.

The preparation of teachers for the rural common schools, E. BURNHAM (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 152-155*).—After discussing some of the essentials of training for rural school teachers, the author considers the county normal training classes now in vogue in Michigan and the courses for rural teachers in the State normal schools.

The school garden and the country school, G. D. FULLER (*Ottawa Nat., 19 (1906), No. 12, p. 235-246, dgm. 1*).—An account of school garden work in connection with a Macdonald rural school at Brome, Quebec, giving particulars regarding the conduct of the garden work during the winter and spring terms, and in the summer vacation.

True nature study: Its fundamentals and its relation to some other subjects, J. V. CRONE (*Nature-Study Rev., 2 (1906), No. 5, pp. 177-184*).

Nature study and gardening, ESTELLE REEL (*Washington: Govt. Printing Office, 1905, pp. 27, figs. 4*).—A bulletin giving suggestions to teachers in Indian schools regarding nature study lessons, window boxes, and gardening.

Education in Indian rural schools. A plea for nature study, F. G. SLY (*Agr. Jour. India, 1 (1906), No. 2, pp. 115-122*).—An argument for rural school instruction dealing with concrete objects before abstract, proceeding from the known to the unknown, and basing instruction upon the familiar surroundings of the child.

"The familiar surroundings of the rural school boy are essentially agricultural, so that his education should very largely be based upon agriculture." A distinction is made between teaching agriculture, which is not recommended, and teaching nature study through the use of agricultural material, which is strongly urged. Suggestions are given for training teachers in cooperation between the education and agricultural departments of India.

Royal Hungarian Central Viticultural Institute (*L'Institut Central Ampelologique Royal Hongrois. Budapest, 1905, pp. 15, figs. 6, dgms. 2*).—This is a description of the organization, buildings, and other equipment of the Royal Hungarian Central Viticultural Institute opened at Budapest in 1904. The institute includes divisions of

biology, chemistry, zymology, and viticulture and enology, each under a chief subordinate to the director of the institute. The buildings include a main building containing offices, library, museum, auditorium, lecture rooms, and laboratories, and 4 separate laboratory buildings, one for each division. In the vicinity of the buildings are several vineyards containing American and European vines and hybrids.

Agricultural education in India, J. Harward (*Trop. Agr. and Mag. Ceylon Agr. Soc., 25 (1905), No. 5, pp. 717-722*).—An historical and general account of agricultural education in India, including the work done in agricultural colleges, secondary schools, and rural schools.

Schools for colonial agriculture, Reinecke (*Tropenpflanzer, 10 (1906), No. 4, pp. 238-243*).—An account is given of the schools for colonial agriculture existing in the different countries of Europe and European colonies.

MISCELLANEOUS.

Fourteenth Annual Report of Colorado Station, 1901 (*Colorado Sta. Rpt. 1901, pp. 53*).—This report, recently issued, contains a financial statement for the fiscal year ended June 30, 1901; and reports of the director, heads of departments, and field agents of the station, parts of which are abstracted elsewhere in this issue. The report of the Plains Substation includes notes on weather conditions, various horticultural and field crops grown during the year, stock raising, irrigation, and other topics.

Report of Florida Station, 1903 (*Florida Sta. Rpt. 1903, pp. 19*).—This contains a report of the director, a financial statement for the fiscal years ended June 30, 1902-3, a list of the bulletins issued by the station, and brief reports of the heads of departments.

Report of Florida Station, 1904 (*Florida Sta. Rpt. 1904, pp. 22*).—This contains a report of the director, a financial statement for the fiscal year ended June 30, 1904, departmental reports, and a list of the publications of the station available for distribution.

Seventeenth Annual Report of Illinois Station, 1904 (*Illinois Sta. Rpt. 1904, pp. 13*).—This contains a brief statement concerning the principal lines of station work during 1904, a list of the bulletins published by the station, and a financial statement for the fiscal year ended June 30, 1904.

Twentieth Annual Report of Maine Station, 1904 (*Maine Sta. Rpt. 1904, pp. 226*).—This is made up entirely of reprints of Bulletins 100-111 of the station which were issued during the year.

Twenty-first Annual Report of Maine Station, 1905 (*Maine Sta. Rpt. 1905. pp. 268*).—This is made up entirely of reprints of Bulletins 112-124 which were issued during the year.

Fourteenth Annual Report of New Mexico Station, 1903 (*New Mexico Sta. Rpt. 1903, pp. 30*).—This contains a report of the director on the work of the station during the year with a list of press bulletins issued, periodicals received by the station, and a list of the available bulletins and reports to date. Departmental reports containing in some instances experimental work are included and a financial statement is given for the fiscal year ended June 30, 1903.

Twenty-third Annual Report of the New York State Station, 1904 (*New York State Sta. Rpt. 1904, pp. 457*).—This contains a financial statement for the year ended September 30, 1904, a list of periodicals received by the station, meteorological observations noted elsewhere, and reprints of Bulletins 245-260 of the station.

Ohio Agricultural Experiment Station (*Ohio Sta. Circ. 48, pp. 3*).—This calls attention to the nature and results of the work of the station as a justification for asking for an increase in the State appropriation.

Fifteenth Annual Report of Wyoming Station, 1905 (*Wyoming Sta. Rpt. 1905, pp. 77*).—This includes the organization list, a report of the director on the work and publications of the station during the year, a financial statement for the fiscal year ended June 30, 1905, and reports of the heads of departments, parts of which are noted elsewhere. The director's report contains also statements concerning recent State legislation of interest to the station.

A report on lamb feeding experiments has been noted from another publication (E. S. R., 17, p. 688). Analyses of forage plants are reprinted from Bulletin 65 of the station (E. S. R., 17, p. 240).

Report of the Secretary of Agriculture, 1905, JAMES WILSON (*U. S. Dept. Agr., Rpt. 81, pp. 100*).—This is a separate of the Secretary's report previously noted (E. S. R., 17, p. 923).

Publications of the Office of Experiment Stations issued during 1905 and station publications received by the Office of Experiment Stations during 1905 (*U. S. Dept. Agr., Office Expt. Stas. Circ. 66, pp. 14*).—Previous lists of this kind have been published in the bulletins and annual reports of this Office, and recently reprinted and distributed in the form of separates, which with the present circular furnishes a complete list of all the publications of this Office and the experiment stations since their organization up to the end of 1905.

Accessions to the Department Library, 1906 (*U. S. Dept. Agr., Library Bul. 59, pp. 77*).

NOTES.

Alabama College and Station.—W. T. Clarke, assistant superintendent of university extension and assistant in entomology of the California University and Station, has been appointed entomologist of the station. W. Gilder, a graduate of the veterinary college of Cornell University, has been appointed assistant in veterinary science, vice I. S. McAdory, resigned. D. T. Gray has been promoted to assistant professor of animal industry. E. R. Miller, formerly in charge of the department of pharmacy and recently connected with the Cuban experiment station, has been elected professor of pharmaceutical chemistry, vice W. H. Blome, resigned to engage in commercial pursuits.

Connecticut State Station.—The station entomologist is devoting his attention to the gypsy moth, which has made its appearance in the State. One square mile of territory near Stonington is said to have been invaded.

Georgia College.—The State legislature has appropriated $100,000 for the purpose of erecting and equipping buildings for the agricultural college. Through the efforts of the alumni of the institution, the university has recently acquired 500 acres of land adjoining the campus.

Illinois University and Station.—W. C. Coffey has been appointed instructor in sheep husbandry and D. O. Barto instructor in agriculture. Mr. Barto will make a study of those phases of agriculture suitable for use in secondary schools. The following additions have been made to the station staff: L. Hagenaur and A. F. Kidder, department of agronomy; H. O. Allison, department of animal husbandry; and J. M. Barnhart, department of dairy husbandry.

Kentucky Station.—George Roberts has been appointed assistant chemist.

Maryland Station.—C. W. Melick, assistant in dairy husbandry at the Kansas Agricultural College, has been appointed dairyman of the station to take effect September 1. H. Jennings, a graduate of Cornell University, in the class of 1906, has been appointed poultryman to take effect September 1. E. H. Brinkley, formerly of the station, has been appointed assistant in demonstration work to take effect October 1. The last two positions have been provided for by station appropriations.

Massachusetts Station.—L. S. Walker was appointed assistant chemist in the division of foods and feeding July 1, vice A. C. Whittier, resigned.

New Hampshire College.—Dr. T. J. Headlee has been appointed entomologist and F. W. Putnam assistant professor of drawing.

Cornell University.—Dr. T. L. Lyon, recently appointed professor of experimental agronomy in the college of agriculture, will devote his time to research, taking up his work about September 1. Dr. G. F. Warren, horticulturist of the New Jersey Station, has been appointed assistant professor of agronomy. E. O. Fippin, heretofore detailed by the Bureau of Soils of this Department, will remain with the university as assistant professor of agronomy with reference to soils. J. W. Gilmore, instructor in agronomy, has been made assistant professor of agronomy. The college of agriculture now has six professors in agronomy. C. F. Clark has been appointed assistant agronomist.

New York State Station.—Director W. H. Jordan has been granted a four months' leave of absence, the first half of which he will spend in the West. E. B. Hart, associate chemist, has resigned to accept the position of professor of agricultural chemistry in the University of Wisconsin, and chemist of the experiment station. Increased appropriations for the next fiscal year have permitted the following promotions and additions to the station staff: W. J. Schoene, assistant entomologist; James Wilson, of the Oklahoma Agricultural College, assistant bacteriologist; Richard Wellington, of the Massachusetts Agricultural College, assistant horticulturist; and G. T. French, of the Massachusetts Agricultural College, assistant botanist.

Ohio Station.—Edmund Secrest, a graduate of the Kansas Agricultural College and recently connected with the Forest Service of this Department, has been appointed assistant in forestry at the station.

Oklahoma Station.—W. L. English, a graduate of the Oklahoma Agricultural and Mechanical College, for some time assistant in animal husbandry in the college and station, and at present engaged in farming in Pottawatomie County, Okla., has been appointed director of the Oklahoma Agricultural Experiment Station, and will assume the duties of the position September 1, 1906.

Rhode Island College and Station.—Dr. Cooper Curtice has resigned to take up work in the Bureau of Animal Industry of this Department in connection with the eradication of the Texas fever tick. J. G. Halpin, instructor in poultry husbandry in the college, has resigned to accept a similar position in the Michigan Agricultural College. J. W. Bolte, a graduate of the Michigan Agricultural College and poultryman of the Utah College and Station, has been appointed assistant professor of animal industry and will have charge of poultry instruction. He will also be connected with the experiment station. Prof. F. C. Black, of the Indiana Normal University and College of Applied Science, has been appointed to the chair of highway engineering and will begin his new duties in September.

Tennessee Station.—S. E. Barnes, dairyman of the station, has been engaged by the dairy division of the Bureau of Animal Industry to do field work in Tennessee in the interests of dairying, in which work he will cooperate with the station. The vacancy has been filled by the appointment of J. N. Price. L. R. Neel has been appointed assistant in plat work, vice J. E. Converse, resigned to become manager of a farm in the vicinity of Knoxville.

Utah Station.—James Dryden, formerly connected with the station and more recently poultryman of the Montana Station and at present with the Cyphers Incubator Company, of Buffalo, N. Y., has been appointed poultryman, vice J. W. Bolte, resigned. C. Larsen, assistant in dairying at the Iowa College and Station, has been appointed dairyman to fill the vacancy caused by the resignation of J. A. Crockett, who will engage in private business.

Virginia College and Station.—Prof. R. J. Davidson, dean of the scientific department and chemist of the station, has severed his relations with the station in order to devote his entire time to the scientific department. The vacancy on the station staff has been filled by the appointment of Dr. W. B. Ellett, assistant chemist of the station. It is planned to reorganize the department with a first assistant and one or two laboratory assistants and to undertake new lines of investigation made possible by the Adams Act. W. L. Owen, recently appointed to take charge of the cooperative investigations in light tobacco at Chatham, Va., has resigned to accept a position in bacteriology in the Georgia Station. The vacancy has been filled by the appointment of R. P. Cocke. The State farmer's institute recently held at Roanoke was attended by 1,200 farmers, of whom 1,050 visited the college and station on a special train provided for their accommodation.

Bequest to the University of California.—The estate of the late M. Theodore Kearney, near Fresno, comprising about 5,000 acres of land, valued at nearly $1,000,000 and yielding an annual income of about $50,000, has been bequeathed to the University

of California, preferably for endowment of agricultural education and research. President Wheeler has expressed his belief that the trustees of the university will assume the responsibilities involved in accepting this trust.

International Congress of Agriculture.—The Eighth International Congress of Agriculture will be held at Vienna, Austria, May 21–25, 1907. The previous Congresses were held at Paris, 1889; The Hague, 1891; Brussels, 1895; Budapest, 1896; Lausanne, 1898; Paris, 1900, and Rome, 1903. A pamphlet has been issued giving the organization, regulations, and programme of the forthcoming congress. This contains the subjects for discussion of each of the eleven sections in which the congress is to be divided. All reports intended for the congress should be sent to the executive committee before December 1, 1906. Persons desirous of becoming members should notify the executive committee and pay the membership fee of 20 kronen ($4) before March 31, 1907. The secretary of the executive committee is Prof. Josef Häusler, Vienna, Austria, I. Schauflergasse 6.

Indian forestry college.—In order to make better provisions for research work in forestry, and to secure a permanent staff of forest experts for scientific research, as well as for training candidates for the government and state forestry service, the Imperial Forestry School at Dehra Dun, India, has been enlarged and hereafter will be known as the Imperial Forestry Research Institute and College. The college staff will include officers of the imperial service, holding the following positions: (1) Sylviculturist, who will make sylviculture his special study. (2) Superintendent of Forest Working Plans, who will collect and collate statistics of the results of forestry management throughout India. (3) Forest Zoologist, who will investigate the damages caused by insects and other pests. (4) Forest Botanist, who will study the botany of forest plants, distribution of species, diseases of forest trees, etc. (5) Forest Chemist, who will investigate the chemical properties of soils and forest produce. (6) Forest Economist, who will study economic methods of commercial timber production and marketing.

These officers, while engaged primarily in research work, will each deliver a course of lectures on his special subject in the college, and take part in the training of the students. The work of instruction, however, will for the most part be carried on by four assistant instructors.

Miscellaneous.—*Science Progress*, published in London from 1894 to 1898, has been revived under the name *Science Progress in the Twentieth Century*. The journal is to be issued quarterly. The first number contains, among others, articles on The Solvent Action of Roots upon the Soil Particles, by A. D. Hall; On the Occurrence of Prussic Acid and its Derivatives in Plants, by T. A. Henry; Some Notable Instances of the Distribution of Injurious Insects by Artificial Means, by F. V. Theobald; The Corn Smuts and their Propagation, by T. Johnson; and the Utilization of Proteids in the Animal, by F. G. Hopkins.

J. B. Mowry has been appointed commissioner of forestry in Rhode Island.

William Farrer, wheat specialist to the department of agriculture of New South Wales, died April 17, 1906. Mr. Farrer was noted especially for his work in the improvement of wheat by cross-breeding and selection, particularly in the direction of producing types resistant to rust and drought.

Prof. Gustav W. Lehman, prominent as a food chemist, died in Baltimore, August 5, 1906.

Dr. George W. Atherton, president of The Pennsylvania State College, died at that place July 24, 1906.

Last autumn, in the hope that a milder climate might be helpful, he went to southern California, where he spent the winter. Although the change for a time seemed beneficial, yet the relief proved to be but temporary. Upon his return home he gradually grew weaker until his disease culminated in death. At the last commencement, although extremely weak, he expressed a desire to meet the graduating

class and confer the degrees. This was his last public service to the institution over which he had presided for 24 years.

During his presidency the college developed from an institution with a small number of students, few buildings, and an inadequate teaching force to its present large attendance, ample equipment, and high position as an educational institution. Much of this progress was due to Doctor Atherton's indefatigable energy and intelligent interest in the development of technical education.

Doctor Atherton was born in Boxford, Mass., June 20, 1837. At the age of 12 his father died, leaving him with his mother and sister only partially provided for. His first employment was in a cotton mill, and later upon a farm. He worked his way through Philips Exeter Academy and Yale College, being graduated from the latter institution in 1863. He served in the civil war from 1861-63 as lieutenant and captain in the Tenth Connecticut Volunteers; was a teacher in the Albany Boys' Academy, 1863-67; professor in St. John's College, Annapolis, Md., 1867-68, and in the University of Illinois, 1868-69; was professor of political economy in Rutgers College, New Jersey, 1869-82; and president of The Pennsylvania State College, 1882-1906. The degree of LL.D. was conferred upon him by Franklin and Marshall College in 1883. He was one of the original organizers of the Association of American Agricultural Colleges and Experiment Stations, and was the first president of the organization.

INDEX OF NAMES.

O

INDEX OF SUBJECTS.

NOTE.—The abbreviations "Ala. College," "Conn. State," "Mass ," etc., after entries refer to the publications of the respective experiment stations; "Alaska," "Hawaii," and "P. R." to those of the experiment stations in Alaska Hawaii. and Porto Rico; "Can." to those of the experiment stations in Canada, and "U. S. D. A." to those of this Department.

O
